Abstract

The Casimir energies and pressures for a massless scalar field associated with $\delta$-function potentials in 1 + 1 and 3 + 1 dimensions are calculated. For parallel plane surfaces, the results are finite, coincide with the pressures associated with Dirichlet planes in the limit of strong coupling, and for weak coupling do not possess a power-series expansion in 1 + 1 dimension. The relation between Casimir energies and Casimir pressures is clarified, and the former are shown to involve surface terms. The Casimir energy for a $\delta$-function spherical shell in 3 + 1 dimensions has an expression that reduces to the familiar result for a Dirichlet shell in the strong-coupling limit. However, the Casimir energy for finite coupling possesses a logarithmic divergence first appearing in third order in the weak-coupling expansion, which seems unremovable. The corresponding energies and pressures for a derivative of a $\delta$-function potential for the same spherical geometry generalizes the TM contributions of electrodynamics. Cancellation of divergences can occur between the TE ($\delta$-function) and TM (derivative of $\delta$-function) Casimir energies. These results clarify recent discussions in the literature.

I. INTRODUCTION

Since the inception of quantum mechanics, divergences associated with zero-point energy have caused much confusion. One way to deal with them was to simply define them away. This view, however, appears to be untenable, in view of the observable consequence of zero-point fluctuations in the Casimir effect, well probed experimentally [1, 2]. Calculations of such forces, and of the associated energies, are generically plagued with infinities. One modern consensus is that Casimir forces between distinct bodies may be unambiguously computed, while self-stresses (the very concept of which is only somewhat hazily understood) are typically divergent. There are some famous counterexamples: Boyer’s result for the Casimir energies of a perfectly conducting spherical shell [3], and its generalizations to other geometries [4], dimensions [5, 6], and fields [7, 8]. Even situations which possess manifestly divergent energies, such as a dielectric ball [9], possess unambiguous finite dilute limits [10, 11], attributable to van der Waals forces [12].

Although these difficulties have been known since at least 1979 [3, 13, 14, 15], recently they were rediscovered and reexamined in a series of papers by the MIT group [16, 17, 18, 19, 20, 21]. Perhaps more heat that light has been generated by some of the recent discussions. It is the aim of the present paper to put the discussion on a somewhat clearer footing by examining Casimir energies and pressures of massless scalar fields in a $\delta$-function potential background. (This is what the MIT group now refer to as the “sharp” limit [20].) It is then possible to solve the problem exactly, and study how the result depends on the strength of the coupling. Although such calculations have been presented by the MIT group [17, 18, 20, 21] based on the summation of Feynman diagrams, they seem not to have appreciated that Casimir energies for such potentials were first computed by the Leipzig group. The first calculations with planar $\delta$-function potentials were those of Bordag et al. [22], who found equivalent expressions for the Casimir energies given later in Refs. [20, 21]. The corresponding spherical problem was studied first by Bordag et al. [23], who found a nonvanishing second heat kernel coefficient, indicating that the Casimir energy was divergent in third order in the coupling. After a perhaps dubious renormalization, Scandurra [24] extracted the finite part. Recently, Barton [25] has carried out related calculations, modeling a Fullerine molecule to control and physically interpret the divergences, and examining the TE and TM electromagnetic modes, with conclusions not too dissimilar from those of the MIT group.

Although, therefore, this model seems quite well-studied, it is perhaps worthwhile to reexamine it in what I consider the most physically transparent Green’s function approach, to see if some clarity can be brought to what seems at present a rather confused situation. In so doing, we shall clarify the discussion of the perturbative expansion, and learn that it is only the strong-coupling limit of the spherical Casimir energy that possess a finite self-stress, unless cancellations can occur between TE and TM modes (which certainly do occur in the strong coupling limit).

This paper is laid out as follows. In the next section, we find the Casimir pressure for a massless scalar interacting with two $\delta$-function potentials in one spatial dimension. (Equivalently, this is a spherical geometry in one dimension.) The pressure is completely finite, but is nonanalytic in the coupling for weak coupling. The Casimir energy receives

---

1 Barton [25] refers to my approach as “older methods,” but he employs methods of Debye going back to early in the previous century, and other classic techniques. I certainly feel in good company if I use the propagation functions invented by Green, as well as Debye expansions.
contributions from the boundaries (surface terms). The generalization to δ-function planes in three dimensions is immediate, and given in Sec. III. Sec. IV presents the corresponding calculation for the Casimir energy of a massless scalar interacting with a spherical δ-function shell. That resulting expression, in the strong-coupling limit, reduces to the standard one for a Dirichlet shell, yielding a finite self-energy [26]. However, for any finite coupling, the expression possesses an irremovable logarithmic divergence, which first appears in third-order in the weak-coupling expansion [20, 21, 23], although in second order, as noted previously [26], the energy is finite. Section V presents the Casimir energy and pressure for a spherical derivative of a δ-function potential, which, in the strong coupling limit, corresponds to the TM modes of electrodynamics. (The Dirichlet modes computed in Sec. IV correspond to the TE modes.) Concluding remarks are offered in Sec. VI.

II. 1 + 1 DIMENSIONS

We consider a massive scalar field (mass µ) interacting with two δ-function potentials, one at \( x = 0 \) and one at \( x = a \), which has an interaction Lagrange density

\[
\mathcal{L}_{\text{int}} = -\frac{\lambda}{2a} \delta(x) \phi^2(x) - \frac{\lambda'}{2a} \delta(x - a) \phi^2(x),
\]

where we have chosen the coupling constants \( \lambda \) and \( \lambda' \) to be dimensionless. (But see the following.) The Casimir energy for this situation may be computed in terms of the Green’s function

\[
G(x, x') = i \langle T \phi(x) \phi(x') \rangle,
\]

which has a time Fourier transform,

\[
G(x, x') = \int \frac{d\omega}{2\pi} e^{-i\omega(t-t')} g(x, x'; \omega),
\]

which in turn satisfies

\[
\left[ -\frac{\partial^2}{\partial x^2} + \kappa^2 + \frac{\lambda}{a} \delta(x) + \frac{\lambda'}{a} \delta(x - a) \right] g(x, x') = \delta(x - x').
\]

Here \( \kappa^2 = \mu^2 - \omega^2 \). This equation is easily solved, with the result

\[
g(x, x') = \frac{1}{2\kappa} e^{-\kappa|x-x'|} + \frac{1}{2\kappa\Delta} \left[ \frac{\lambda\lambda'}{(2\kappa a)^2} e^{2\kappa |x-x'|} \right.
\]

\[
- \frac{\lambda}{2\kappa a} \left( 1 + \frac{\lambda'}{2\kappa a} \right) e^{2\kappa a} e^{-\kappa(x+x')} - \frac{\lambda'}{2\kappa a} \left( 1 + \frac{\lambda}{2\kappa a} \right) e^{\kappa(x+x')} \] (2.5a)

for both fields inside, \( 0 < x, x' < a \), while if both field points are outside, \( a < x, x' \),

\[
g(x, x') = \frac{1}{2\kappa} e^{-\kappa|x-x'|} + \frac{1}{2\kappa\Delta} e^{-\kappa(x+x'-2a)} \left[ - \frac{\lambda}{2\kappa a} \left( 1 - \frac{\lambda'}{2\kappa a} \right) - \frac{\lambda'}{2\kappa a} \left( 1 + \frac{\lambda}{2\kappa a} \right) e^{2\kappa a} \right].
\] (2.5b)
For \( x, x' < 0 \),
\[
g(x, x') = \frac{1}{2\kappa}e^{-\kappa|x-x'|} + \frac{1}{2\kappa\Delta}e^{-\kappa(x+x'-2a)} \left[ -\frac{\lambda}{2\kappa a} \left( 1 + \frac{\lambda'}{2\kappa a} \right) - \frac{\lambda'}{2\kappa a} \left( 1 - \frac{\lambda}{2\kappa a} \right) e^{2\kappa a} \right].
\] (2.5c)

Here, the denominator is
\[
\Delta = \left( 1 + \frac{\lambda}{2\kappa a} \right) \left( 1 + \frac{\lambda'}{2\kappa a} \right) e^{2\kappa a} - \frac{\lambda\lambda'}{(2\kappa a)^2}.
\] (2.6)

Note that in the strong coupling limit we recover the familiar results, for example, inside
\[
\lambda, \lambda' \to \infty : \quad g(x, x') \to -\frac{\sinh \kappa x < \sinh \kappa (x-a)}{\kappa \sinh \kappa a}.
\] (2.7)

We can now calculate the force on one of the \( \delta \)-function points by calculating the discontinuity of the stress tensor, obtained from the Green’s function by
\[
\langle T^{\mu\nu} \rangle = \left( \partial^{\mu} \partial^{\nu} - \frac{1}{2} g^{\mu\nu} \partial^{\lambda} \partial_{\lambda} \right) \frac{1}{i} G(x, x') \bigg|_{x=x'}.
\] (2.8)

Writing
\[
\langle T^{\mu\nu} \rangle = \int \frac{d\omega}{2\pi} t^{\mu\nu},
\] (2.9)
we find inside
\[
t_{xx} = \frac{1}{2i}(\omega^2 + \partial_x \partial_{x'})g(x, x') \bigg|_{x=x'}
\]
\[
= \frac{1}{4i\kappa\Delta} \left\{ (2\omega^2 - \mu^2) \left[ \left( 1 + \frac{\lambda}{2\kappa a} \right) \left( 1 + \frac{\lambda'}{2\kappa a} \right) e^{2\kappa a} + \frac{\lambda\lambda'}{(2\kappa a)^2} \right] 
- \mu^2 \left[ \frac{\lambda}{2\kappa a} \left( 1 + \frac{\lambda'}{2\kappa a} \right) e^{-2\kappa(x-a)} + \frac{\lambda'}{2\kappa a} \left( 1 + \frac{\lambda}{2\kappa a} \right) e^{2\kappa x} \right] \right\}.
\] (2.10)

Let us henceforth simplify the considerations by taking the massless limit, \( \mu = 0 \). Then the stress tensor just to the left of the point \( x = a \) is
\[
t_{xx} \bigg|_{x=a-} = -\frac{\kappa}{2i} \left\{ 1 + 2 \left[ \left( \frac{2\kappa a}{\lambda} + 1 \right) \left( \frac{2\kappa a}{\lambda'} + 1 \right) e^{2\kappa a} - 1 \right]^{-1} \right\}.
\] (2.11)

From this we must subtract the stress just to the right of the point at \( x = a \), obtained from Eq. (2.5b), which turns out to be in the massless limit
\[
t_{xx} \bigg|_{x=a+} = -\frac{\kappa}{2i},
\] (2.12)
which just cancels the 1 in braces in Eq. (2.11). Thus the force on the point \( x = a \) due to the quantum fluctuations in the scalar field is given by the simple, finite expression
\[
F = \langle T_{xx} \rangle \bigg|_{x=a-} - \langle T_{xx} \rangle \bigg|_{x=a+} = -\frac{1}{4\pi a^2} \int_0^\infty dy \frac{1}{y(y+1)(y+1)e^y - 1}.
\] (2.13)
This reduces to the well-known, Lüscher result \[27, 28\] in the limit \(\lambda, \lambda' \to \infty\),

\[
\lim_{\lambda=\lambda' \to \infty} F = -\frac{\pi}{24a^2},
\]

(2.14)

and for \(\lambda = \lambda'\) is plotted in Fig. 1.

We can also compute the energy density. In this simple massless case, the calculation appears identical, because \(t_{xx} = t_{00}\) (conformal invariance). The energy density is constant [Eq. (2.10) with \(\mu = 0\)] and subtracting from it the \(a\)-independent part that would be present if no potential were present, we immediately see that the total energy is \(E = Fa\), so \(F = -\partial E/\partial a\). This result differs significantly from that given in Refs. \[17, 18, 19\], which is a divergent expression in the massless limit, not transformable into the expression found by this naive procedure. However, that result may be easily derived from the following expression for the total energy,

\[
E = \int (dr) \langle T^{00}\rangle = \frac{1}{2i} \int (dr) \left( \partial^0 \partial^0 - \nabla^2 \right) G(x, x') \bigg|_{x=x'}
\]

\[
= \frac{1}{2i} \int (dr) \int \frac{d\omega}{2\pi} 2\omega^2 G(r, r).
\]

(2.15)

Integrating over the Green’s functions in the three regions, given by Eqs. (2.5a), (2.5b), and (2.5c), we obtain for \(\lambda = \lambda'\),

\[
E = \frac{1}{4\pi a} \int_0^\infty dy \frac{1}{1 + y/\lambda} - \frac{1}{4\pi a} \int_0^\infty dy \frac{1 + 2/(y + \lambda)}{(y/\lambda + 1)^2 e^y - 1},
\]

(2.16)

where the first term is regarded as an irrelevant constant (\(\lambda/a\) is constant), and the second is the same as that given by Eq. (70) of Ref. \[18\] upon integration by parts.

FIG. 1: Casimir force between two \(\delta\)-function points having strength \(\lambda\) and separated by a distance \(a\).
The origin of this discrepancy is the existence of a surface contribution to the energy. Because \( \partial_{\mu}T^{\mu\nu} = 0 \), we have, for a region \( V \) bounded by a surface \( S \),

\[
0 = \frac{d}{dt} \int_V (dx)T^{00} + \int_S dS_i T^{0i}.
\]

Here \( T^{0i} = \partial^0 \phi \partial^i \phi \), so we conclude that there is an additional contribution to the energy,

\[
E_s = -\frac{1}{2} \int dS \cdot \nabla G(x, x') \bigg|_{x' = x} \tag{2.17}
\]

where the derivative is taken at the boundaries (here \( x = 0, a \)) in the sense of the outward normal from the region in question. When this surface term is taken into account the extra terms in Eq. (2.16) are supplied. The integrated formula (2.15) automatically builds in this surface contribution, as the implicit surface term in the integration by parts. (These terms are slightly unfamiliar because they do not arise in cases of Neumann or Dirichlet boundary conditions.) See Fulling [29] for further discussion.

It is interesting to consider the behavior of the force or energy for small coupling \( \lambda \). It is clear that, in fact, Eq. (2.13) is not analytic at \( \lambda = 0 \). (This reflects an infrared divergence in the Feynman diagram calculation.) If we expand out the leading \( \lambda^2 \) term we are left with a divergent integral. A correct asymptotic evaluation leads to the behavior

\[
F \sim \frac{\lambda^2}{4\pi a^2} (\ln 2\lambda + \gamma), \quad E \sim -\frac{\lambda^2}{4\pi a} (\ln 2\lambda + \gamma - 1), \quad \lambda \to 0. \tag{2.19}
\]

This behavior indeed was anticipated in earlier perturbative analyses. In Ref. [26] the general result was given for the Casimir energy for a \( D \) dimensional spherical \( \delta \)-function potential (a factor of \( 1/4\pi \) was inadvertently omitted)

\[
E = -2^{1-2D} \frac{\lambda^2}{\pi a} \frac{\Gamma(D/2)}{\Gamma(D/2)^2} \frac{\Gamma(D-3/2)\Gamma(1-D/2)}{\Gamma(1-D/2)} \tag{2.20}
\]

This possesses an infrared divergence as \( D \to 1 \):

\[
E^{(D=1)} = \frac{\lambda^2}{4\pi a} \Gamma(0), \tag{2.21}
\]

which is consistent with the nonanalytic behavior seen in Eq. (2.19).

### III. PARALLEL PLANES IN 3 + 1 DIMENSIONS

It is trivial to extract the expression for the Casimir pressure between two \( \delta \) function planes in three spatial dimensions, where the background lies at \( x = 0 \) and \( x = a \). We merely have to insert into the above a transverse momentum transform,

\[
G(x, x') = \int \frac{d\omega}{2\pi} e^{-i\omega(t-t')} \int \frac{dk}{(2\pi)^2} e^{i\mathbf{k} \cdot (\mathbf{r} - \mathbf{r}')_{\perp}} g(x, x'; \kappa), \tag{3.1}
\]
where now $\kappa^2 = \mu^2 + k^2 - \omega^2$. Then $g$ has exactly the same form as in Eqs. (2.5). The reduced stress tensor is given by, for the massless case,

$$t_{xx} = \frac{1}{2} (\partial_x \partial_{x'} - \kappa^2) \left. g(x, x') \right|_{x=x'},$$

(3.2)

so we immediately see that the attractive pressure on the planes is given by ($\lambda = \lambda'$)

$$P = -\frac{1}{32\pi^2 a^4} \int_0^{\infty} dy \frac{y^3}{(y/\lambda + 1)^2 e^y - 1},$$

(3.3)

which coincides with the result given in Refs. [20, 21].

The Casimir energy per unit area again might be expected to be

$$\mathcal{E} = -\frac{1}{96\pi^2 a^3} \int_0^{\infty} dy \frac{y^3}{(y/\lambda + 1)^2 e^y - 1} = \frac{1}{3} \frac{P}{a},$$

(3.4)

because then $P = -\frac{\partial}{\partial a} \mathcal{E}$. In fact, however, it is straightforward to compute the energy density $\langle T^{00}\rangle$ is the three regions, $z < 0$, $0 < z < a$, and $a < z$, and then integrate it over $z$ to obtain the energy/area, which differs from Eq. (3.4) because, now, there exists transverse momentum. We also must include the surface term (2.18a), which is of opposite sign, and of double magnitude, to the $k^2$ term. The net extra term is

$$\mathcal{E}' = -\frac{1}{48\pi^2 a^3} \int_0^{\infty} dy \frac{y^2}{1 + y/\lambda} \left[ 1 - \frac{y/\lambda}{(y/\lambda + 1)^2 e^y - 1} \right].$$

(3.5)

If we regard $\lambda/a$ as constant (so that the strength of the coupling is independent of the separation between the planes) we may drop the first, divergent term here as irrelevant, being independent of $a$, because $y = 2\kappa a$, and then the total energy is

$$\mathcal{E} = -\frac{1}{96\pi^2 a^3} \int_0^{\infty} dy \frac{y^3}{(y/\lambda + 1)^2 e^y - 1},$$

(3.6)

which coincides with the massless limit of the energy first found by Bordag et al. [22], and given in Refs. [20, 21]. As noted in Sec. II, this result may also readily be derived through use of (2.15). When differentiated with respect to $a$, Eq. (3.6), with $\lambda/a$ fixed, yields the pressure (3.3).

IV. THREE-DIMENSIONAL SPHERICAL POTENTIAL

We now carry out the same calculation in three spatial dimensions, with a radially symmetric background

$$\mathcal{L}_{\text{int}} = -\frac{1}{2} \Lambda \delta(r - a) \phi^2(x),$$

(4.1)

which would correspond to a Dirichlet shell in the limit $\lambda \to \infty$. The time-Fourier transformed Green’s function satisfies the equation ($\kappa^2 = -\omega^2$)

$$\left[ -\nabla^2 + \kappa^2 + \frac{\Lambda}{a} \delta(r - a) \right] G(r, r') = \delta(r - r').$$

(4.2)
We write $G$ in terms of a reduced Green’s function

$$G(r, r') = \sum_{lm} g_l(r, r') Y_{lm}(\Omega) Y^*_{lm}(\Omega'),$$

where $g_l$ satisfies

$$\left[ -\frac{1}{r^2} \frac{d}{dr} r^2 \frac{d}{dr} + \frac{l(l+1)}{r^2} + \kappa^2 + \frac{\lambda}{\kappa} \delta(r-a) \right] g_l(r, r') = \frac{1}{r^2} \delta(r-r').$$

We solve this in terms of modified Bessel functions, $I_{\nu}(x)$, $K_{\nu}(x)$, where $\nu = l + 1/2$, which satisfy the Wronskian condition

$$I'_{\nu}(x)K_{\nu}(x) - K'_{\nu}(x)I_{\nu}(x) = \frac{1}{x}.$$  \hspace{1cm} (4.5)

We solve Eq. (4.4) by requiring continuity of $g_l$ at each singularity, $r'$ and $a$, and the appropriate discontinuity of the derivative. Inside the sphere we then find ($0 < r, r' < a$)

$$g_l(r, r') = \frac{1}{\kappa r'} \left[ e_l(\kappa r_r) s_l(\kappa r_u) - \frac{\lambda}{\kappa a} s_l(\kappa r_r) s_l(\kappa r_u) \right] \cdot \frac{e_l^2(\kappa a)}{1 + \frac{\lambda}{\kappa a} s_l(\kappa a) e_l(\kappa a)}.$$  \hspace{1cm} (4.6)

Here we have introduced the modified Riccati-Bessel functions,

$$s_l(x) = \sqrt{\frac{\pi x}{2}} I_{l+1/2}(x), \quad e_l(x) = \sqrt{\frac{2x}{\pi}} K_{l+1/2}(x).$$  \hspace{1cm} (4.7)

Note that Eq. (4.6) reduces to the expected result, vanishing as $r \to a$, in the limit of strong coupling:

$$\lim_{\lambda \to \infty} g_l(r, r') = \frac{1}{\kappa r'} \left[ e_l(\kappa r_r) s_l(\kappa r_u) - \frac{e_l(\kappa a)}{s_l(\kappa a)} s_l(\kappa r_r) s_l(\kappa r_u) \right].$$  \hspace{1cm} (4.8)

When both points are outside the sphere, $r, r' > a$, we obtain a similar result:

$$g_l(r, r') = \frac{1}{\kappa r'} \left[ e_l(\kappa r_r) s_l(\kappa r_u) - \frac{\lambda}{\kappa a} e_l(\kappa r_r) e_l(\kappa r_u) \right] \cdot \frac{s_l^2(\kappa a)}{1 + \frac{\lambda}{\kappa a} s_l(\kappa a) e_l(\kappa a)}.$$  \hspace{1cm} (4.9)

which similarly reduces to the expected result as $\lambda \to \infty$.

Now we want to get the radial-radial component of the stress tensor to get the pressure on the sphere, which is obtained by applying the operator

$$\partial_r \partial_r - \frac{1}{2} (-\partial^0 \partial^0 + \nabla \cdot \nabla') \to \frac{1}{2} \partial_r \partial_r - \kappa^2 - \frac{l(l+1)}{r^2}$$

(4.10)

to the Green’s function, where in the last term we have averaged over the surface of the sphere. In this way we find, from the discontinuity of $\langle T_{rr} \rangle$ across the $r = a$ surface, the net stress

$$F = \frac{\lambda}{2\pi a^2} \sum_{l=0}^{\infty} (2l+1) \int_0^\infty dx \left[ \frac{(e_l(x)s_l(x))^' - \frac{2e_l(x)s_l(x)}{x}}{1 + \frac{\lambda e_l(x)s_l(x)}{x}} \right].$$  \hspace{1cm} (4.11)

The same result can be deduced by computing the total energy (2.15). The free Green’s function, the first term in Eqs. (4.6) or (4.9), evidently makes no significant contribution to
the energy, for it gives a term independent of the radius of the sphere, \( a \), so we omit it. The remaining radial integrals are simply

\[
\int_0^x dy \, s_l^2(y) = \frac{1}{2x} \left[ (x^2 + l(l + 1)) s_l^2 + xs_l s'_l - x^2 s_l'^2 \right],
\]

(4.12a)

\[
\int_x^\infty dy \, c_l^2(y) = -\frac{1}{2x} \left[ (x^2 + l(l + 1)) c_l^2 + xc_l c'_l - x^2 c_l'^2 \right],
\]

(4.12b)

where all the Bessel functions on the right-hand-sides of these equations are evaluated at \( x \).

Then using the Wronskian, we find that the Casimir energy is

\[
E = -\frac{1}{2\pi a} \sum_{l=0}^{\infty} (2l + 1) \int_0^\infty dx \, x \frac{d}{dx} \ln [1 + \lambda I_\nu(x) K_\nu(x)],
\]

(4.13)

If we differentiate with respect to \( a \), with \( \lambda / a \) fixed, we immediately recover the force (4.11).

This expression, upon integration by parts, coincides with that given by Barton [25], and was first analyzed in detail by Scandurra [24]. It reduces to the well-known expression for the Casimir energy of a massless scalar field inside and outside a sphere upon which Dirichlet boundary conditions are imposed, that is, that the field must vanish at \( r = a \):

\[
\lim_{\lambda \to \infty} E = -\frac{1}{2\pi a} \sum_{l=0}^{\infty} (2l + 1) \int_0^\infty dx \, x \frac{d}{dx} \ln [I_\nu(x) K_\nu(x)],
\]

(4.14)

because multiplying the argument of the logarithm by a power of \( x \) is without effect, corresponding to a contact term. Details of the evaluation of Eq. (4.14) are given in Ref. [26].

The opposite limit is of interest here. The expansion of the logarithm is immediate for small \( \lambda \). The first term, of order \( \lambda \), is evidently divergent, but irrelevant, since that may be removed by renormalization of the tadpole graph. In contradistinction to the claim of Refs. [17, 18, 20, 21], the order \( \lambda^2 \) term is finite, as claimed in Ref. [26]. That term is

\[
E^{(\lambda^2)} = \frac{\lambda^2}{4\pi a} \sum_{l=0}^{\infty} (2l + 1) \int_0^\infty dx \, x \frac{d}{dx} [I_{l+1/2}(x) K_{l+1/2}(x)]^2.
\]

(4.15)

The sum on \( l \) can be carried out using a trick due to Klich [30]: The sum rule

\[
\sum_{l=0}^{\infty} (2l + 1) c_l(x) s_l(y) P_l(\cos \theta) = \frac{xy}{\rho} e^{-\rho},
\]

(4.16)

where \( \rho = \sqrt{x^2 + y^2 - 2xy \cos \theta} \), is squared, and then integrated over \( \theta \), according to

\[
\int_{-1}^1 d \cos \theta P_l(\cos \theta) P_{l'}(\cos \theta) = \delta_{ll'} \frac{2}{2l + 1}.
\]

(4.17)

In this way we learn that

\[
\sum_{l=0}^{\infty} (2l + 1) c_l^2(x) s_l^2(y) = \frac{x^2}{2} \int_0^4 w e^{-w}.\]

(4.18)
Although this integral is divergent, because we did not integrate by parts in Eq. (4.15), that
divergence does not contribute:
\[
E^{(\lambda^2)} = \frac{\lambda^2}{4\pi a} \int_{0}^{\infty} dx \frac{1}{2x} \frac{d}{dx} \int_{0}^{4x} \frac{dw}{w} e^{-w} = \frac{\lambda^2}{32\pi a},
\]
which is exactly the result (4.25) of Ref. [26], which also follows from Eq. (2.20) here.

However, before we wax too euphoric, we recognize that the order \(\lambda^3\) term appears
logarithmically divergent, just as Refs. [20] and [21] claim. This does not signal a breakdown
in perturbation theory, as the divergence in the \(D = 1\) calculation did. Suppose we subtract
off the two leading terms,
\[
E = -\frac{1}{2\pi a} \sum_{l=0}^{\infty} (2l + 1) \int_{0}^{\infty} dx x \frac{d}{dx} \left[\ln \left(1 + \lambda I_\nu K_\nu\right) - \lambda I_\nu K_\nu + \frac{\lambda^2}{2} (I_\nu K_\nu)^2\right] + \frac{\lambda^2}{32\pi a}.
\]

To study the behavior of the sum for large values of \(l\), we can use the uniform asymptotic
expansion (Debye expansion),
\[
\nu \gg 1 : \quad I_\nu(x) K_\nu(x) \sim \frac{t}{2\nu} \left[1 + \frac{A(t)}{\nu^2} + \frac{B(t)}{\nu^4} + \ldots\right].
\]
Here \(x = \nu z\), and \(t = 1/\sqrt{1 + z^2}\). The functions \(A\) and \(B\), etc., are polynomials in \(t\). We
now insert this into Eq. (4.20) and expand not in \(\lambda\) but in \(\nu\); the leading term is
\[
E^{(\lambda^3)} \sim \frac{\lambda^3}{24\pi a} \sum_{\nu=0}^{\infty} \frac{1}{\nu} \int_{0}^{\infty} \frac{dz}{(1 + z^2)^{3/2}} \frac{\lambda^3}{24\pi a} \zeta(1).
\]
Although the frequency integral is finite, the angular momentum sum is divergent. The
appearance here of the divergent \(\zeta(1)\) seems to signal an insuperable barrier to extraction
of a finite Casimir energy for finite \(\lambda\).

This divergence has been known for many years, and was first calculated explicitly in
1998 by Bordag et al. [23], where the second heat kernel coefficient gave
\[
E \sim \frac{\lambda^3}{48\pi a} \frac{1}{s}, \quad s \to 0.
\]
A possible way of dealing with this divergence was advocated in Ref. [24].

V. TM SPHERICAL POTENTIAL

Of course, the scalar model considered in the previous section is merely a toy model,
and something analogous to electrodynamics is of far more physical relevance. There are
good reasons for believing that cancellations occur in general between TE (Dirichlet) and
TM (Robin) modes. Certainly they do occur in the classic Boyer energy of a perfectly
conducting spherical shell [3, 31, 32], and the indications are that such cancellations occur
even with imperfect boundary conditions [25]. Following the latter reference, let us consider
the potential
\[
\mathcal{L}_{\text{int}} = \frac{1}{2} \lambda a \frac{1}{r} \frac{\partial}{\partial r} \delta(r - a) \phi^2(x).
\]
In the limit $\lambda \to \infty$ this corresponds to TM boundary conditions. The reduced Green’s function is thus taken to satisfy
\[
\left[ -\frac{1}{r^2} \frac{d}{dr} r^2 \frac{d}{dr} + \frac{l(l+1)}{r^2} + \kappa^2 - \frac{\lambda a}{r} \frac{\partial}{\partial r} \delta(r - a) \right] g_l(r, r') = \frac{1}{r^2} \delta(r - r').
\] (5.2)

At $r = r'$ we have the usual boundary conditions, that $g_l$ be continuous, but that its derivative be discontinuous,
\[
r^2 \frac{d}{dr} g_l \bigg|_{r=r'} = -1,
\] (5.3)
while at the surface of the sphere the derivative is continuous,
\[
\frac{\partial}{\partial r} r g_l \bigg|_{r=a} = 0,
\] (5.4a)
while the function is discontinuous,
\[
g_l \bigg|_{r=a} = -\lambda \frac{\partial}{\partial r} r g_l.
\] (5.4b)

It is then easy to find the Green’s functions. When both points are inside the sphere,
\[
r, r' < a : \quad g_l(r, r') = \frac{1}{\kappa r r'} \left[ s_l(\kappa r) e_i(\kappa r') - \frac{\lambda \kappa a [e'_i(\kappa a)]^2 s_i(\kappa r) s'_i(\kappa r')}{1 + \lambda \kappa a e'_i(\kappa a) s'_i(\kappa a)} \right],
\] (5.5a)
and when both points are outside the sphere,
\[
r, r' > a : \quad g_l(r, r') = \frac{1}{\kappa r r'} \left[ s_l(\kappa r) e_i(\kappa r') - \frac{\lambda \kappa a [s'_i(\kappa a)]^2 e_i(\kappa r) e'_i(\kappa r')}{1 + \lambda \kappa a e'_i(\kappa a) s'_i(\kappa a)} \right].
\] (5.5b)

It is easy to see that these supply the appropriate Robin boundary conditions in the $\lambda \to \infty$ limit:
\[
\lim_{\lambda \to \infty} \frac{\partial}{\partial r} r g_l \bigg|_{r=a} = 0.
\] (5.6)

The Casimir energy may be readily obtained from Eq. (2.15), and we find, using the integrals (4.12),
\[
E = -\frac{1}{2\pi a} \sum_{l=0}^{\infty} (2l + 1) \int_0^{\infty} dx \frac{d}{dx} \ln \left[ 1 + \lambda x e'_i(x) s'_i(x) \right].
\] (5.7)

The force may be obtained from this by applying $-\partial/\partial a$, and regarding $\lambda a$ as constant [see Eq. (5.1)], or directly, from the Green’s function by applying the operator,
\[
t_{rr} = \frac{1}{2i} \left[ \nabla_r \nabla_{r'} - \kappa^2 - \frac{l(l+1)}{r^2} \right] g_l \bigg|_{r'=r},
\] (5.8)
which is the same as that in Eq. (4.10), except that
\[
\nabla_r = \frac{1}{r} \partial_r r,
\] (5.9)
appropriate to TM boundary conditions (see Ref. [6], for example). Either way, the total stress on the sphere is

\[ F = -\frac{\lambda}{2\pi a^2} \sum_{l=0}^{\infty} (2l + 1) \int_0^\infty dx x^2 \frac{[e'_l(x)s'_l(x)]'}{1 + \lambda x e'_l(x)s'_l(x)}. \]  

(5.10)

The result for the energy (5.7) is similar, but not identical, to that given by Barton [25].

Suppose we now combine the TE and TM Casimir energies, Eqs. (4.13) and (5.7):

\[ E^{\text{TE}} + E^{\text{TM}} = -\frac{1}{2\pi a} \sum_{l=0}^{\infty} (2l + 1) \int_0^\infty dx x \frac{d}{dx} \ln \left[ \left(1 + \lambda s_l\right)\left(1 + \lambda e'_l \right) \right]. \]  

(5.11)

In the limit \( \lambda \to \infty \) this reduces to the familiar expression for the perfectly conducting spherical shell [31]:

\[ \lim_{\lambda \to \infty} E = -\frac{1}{2\pi a} \sum_{l=1}^{\infty} (2l + 1) \int_0^\infty dx x \left( \frac{e'_l}{e_l} + \frac{e''_l}{e'_l} + \frac{s'_l}{s_l} + \frac{s''_l}{s'_l} \right). \]  

(5.12)

Here we have, as appropriate to the electrodynamic situation, omitted the \( l = 0 \) mode. This expression yields a finite Casimir energy. What about finite \( \lambda \)? In general, it appears that there is no chance that the divergence found in the previous section in order \( \lambda^3 \) can be cancelled. But suppose the coupling for the TE and TM modes are different. If \( \lambda^{\text{TE}}\lambda^{\text{TM}} = 4 \), a cancellation appears possible.

Let’s illustrate this by retaining only the leading terms in the uniform asymptotic expansions: \( (x = \nu z) \)

\[ \frac{e_l(x)s_l(x)}{x} \sim \frac{t}{2\nu}, \quad xe'_l(x)s'_l(x) \sim -\frac{\nu}{2t}, \quad \nu \to \infty. \]  

(5.13)

Then the logarithm appearing in the integral for the energy (5.11) is approximately

\[ \ln \sim \ln \left(-\frac{\lambda^{\text{TM}}}{2t} \right) + \ln \left(1 + \frac{\lambda^{\text{TE}}}{2\nu} \right) + \ln \left(1 - \frac{2t}{\lambda^{\text{TM}}\nu} \right). \]  

(5.14)

The first term here presumably gives no contribution to the energy, because it is independent of \( \lambda \) upon differentiation, and further we may interpret \( \sum_{l=0}^{\infty} \nu^2 = 0 \) [see Eq. (5.18)]. Now if we make the above identification of the couplings,

\[ \hat{\lambda} = \frac{\lambda^{\text{TE}}}{2} = \frac{2}{\lambda^{\text{TM}}}, \]  

(5.15)

all the odd powers of \( \nu \) cancel out, and

\[ E \sim -\frac{1}{2\pi a} \sum_{l=0}^{\infty} (2l + 1) \int_0^\infty dx x \frac{d}{dx} \ln \left(1 - \frac{\hat{\lambda}^2 t^2}{\nu^2} \right). \]  

(5.16)

The divergence encountered for the TE mode is thus removed, and the power series is simply twice the sum of the even terms there. This will be finite. Presumably, the same is true if the subleading terms in the uniform asymptotic expansion are retained.
It is interesting to approximately evaluate Eq. (5.10). The integral over $z$ may be easily evaluated as a contour integral, leaving

$$E \sim -\frac{1}{a} \sum_{l=0}^{\infty} \nu^2 \left( 1 - \sqrt{1 - \frac{\hat{\lambda}^2}{\nu^2}} \right).$$  \hspace{1cm} (5.17)

This $l$ sum is logarithmic divergent, an artifact of the asymptotic expansion, since we know the $\lambda^2$ term is finite. If we expand the square root for small $\hat{\lambda}^2/\nu^2$, we see that the $O(\hat{\lambda}^2)$ term vanishes if we interpret the sum as

$$\sum_{l=0}^{\infty} \nu^{-s} = (2^s - 1)\zeta(s),$$  \hspace{1cm} (5.18)

in terms of the Riemann zeta function. The leading term is $O(\hat{\lambda}^4)$:

$$E \sim -\frac{\hat{\lambda}^4}{8a} \sum_{l=0}^{\infty} \frac{1}{\nu^2} = \frac{\hat{\lambda}^4\pi^2}{16a}.$$  \hspace{1cm} (5.19)

To recover the correct leading $\lambda$ behavior in (4.19) requires the inclusion of the subleading $\nu^{-2n}$ terms displayed in Eq. (4.21).

Much faster convergence is achieved if we consider the results with the $l = 0$ term removed, as appropriate for electromagnetic modes. Let’s illustrate this for the order $\lambda^2$ TE mode (now, for simplicity, write $\lambda = \lambda^{\text{TE}}$) Then, in place of the energy (4.19) we have

$$\tilde{E}^{\lambda^2} = \frac{\lambda^2}{32\pi a} + \frac{\lambda^2}{4\pi a} \int_0^{\infty} \frac{dx}{x^2} \sinh^2 x e^{-2x} = \frac{\lambda^2}{a} \left( \frac{1}{32\pi} + \frac{\ln 2}{4\pi} \right) = \frac{\lambda^2}{a}(0.0651061).$$  \hspace{1cm} (5.20)

Now the leading term in the uniform asymptotic expansion is no longer zero:

$$E^{(0)} = -\frac{1}{2\pi a} \sum_{l=1}^{\infty} (2l + 1) \int_0^{\infty} dx \frac{d}{dx} \left( -\frac{\lambda^2 t^2}{8\nu^2} \right)$$

$$= \frac{\lambda^2}{8\pi a} \sum_{l=1}^{\infty} \nu^0 \left( -\frac{\pi}{2} \right) = \frac{\lambda^2}{16a} = \frac{\lambda^2}{a}(0.0625),$$  \hspace{1cm} (5.21)

which is 4% lower than the exact answer (5.20). The next term in the uniform asymptotic expansion is

$$E^{(2)} = -\frac{\lambda^2}{4\pi a} \left[ 3\zeta(2) - 4 \right] \int_0^{\infty} dz \frac{t^2}{8} - \frac{6t^4 + 5t^5}{8}$$

$$= \frac{\lambda^2}{a} \left( \frac{3\pi^2}{2048} - \frac{3}{256} \right) = \frac{\lambda^2}{a}(0.0027368),$$  \hspace{1cm} (5.22)

which reduces the estimate to

$$E^{(0)} + E^{(2)} = \frac{\lambda^2}{a}(0.0652368),$$  \hspace{1cm} (5.23)

13
which is now 0.2% high. Going out one more term gives

\[ E^{(4)} = -\frac{\lambda^2}{8\pi a} [15\zeta(4) - 16] \int_0^\infty dz \frac{t^4}{16}(7 - 148t^2 + 554t^4 - 708t^6 + 295t^8) \]

\[ = -\frac{\lambda^2}{a} \frac{59\pi^4}{524288} + \frac{\lambda^2}{a} \frac{177}{16328} = -\frac{\lambda^2}{a} (0.000158570), \]

and the estimate for the energy is now only 0.04% low:

\[ E^{(0)} + E^{(2)} + E^{(4)} = \frac{\lambda^2}{a} (0.06507823). \]

We could also make similar remarks about the TM contributions. However, evidently there are additional subtleties here, so we will defer further discussion for a further publication.

VI. CONCLUSIONS

In this paper we have repeated some calculations with “sharp” but not necessarily “strong” potentials. That is, we have computed Casimir energies in the presence of \( \lambda \delta(x-a) \) potentials, in the cases when the delta function lies on two parallel planes (first considered in Ref. [22]), and when the support of the \( \delta \) function is a sphere (first considered in Ref. [23, 24]). We have also considered spherical potentials of the form \( \lambda \delta'(r-a)/r \). For either spherical potential, the approach given here yields finite result in all orders, except the third, provided we make the coupling constant identification (5.15) in the TM case. That is, the expression for the energy possess a logarithmic divergence entirely associated with the order \( \lambda^3 \) Feynman graph. This was rediscovered by Graham et al. [20, 21], but obscured by the apparent (spurious) divergence they also claimed to find in order \( \lambda^2 \). The bottom line, however, is that these sharp potentials yield a divergent Casimir self-stress.

The generalizations drawn in Graham et al. papers [17, 18, 20, 21] are, however, perhaps too strong. The fact that the \( \lambda \to \infty \) limit of the expression for the energy coincides with that for the Dirichlet shell, does not prove that the latter is divergent. It does, however, suggest that that idealization does not yield the full result for the energy of a configuration defined by a real material boundary. This, of course, is no surprise. It has been recognized since at least 1979 [1, 13] that constructing a shell from real materials will yield apparent divergences as the ideal limit is approached, so for example, a shell of finite thickness made of dielectric material will correspond to a divergent Casimir energy.

So the finite Boyer energy [3] for an ideal sphere results from omitting divergent terms, which may or may not have observable consequences. (It may be, of course, that for electromagnetic modes, the divergence found here could cancel, for which we have provided some evidence.) However, what is remarkable, and of some significance, is that this finite term is unique. For example, Barton has recently exhibited a Buckyball model of a conducting spherical shell that possesses various large energy contributions referring to the material properties of the shell, but which nevertheless possesses a unique, if subdominant, Boyer term of order \( 1/a \) [25].

It may be useful to compare this situation with a slightly better understood example, the Casimir energy of a dielectric sphere. That is certainly divergent; yet if the divergences are isolated in terms that contribute to the volume and surface energies, in order \((\epsilon - 1)^2\) a
unique $1/a$ coefficient emerges [10, 11, 23, 33], which may be interpretable as the van der Waals energy [34]. That coefficient diverges in order $(\epsilon - 1)^3$ [23]. This fact seems to bear a striking resemblance to the finite Casimir energy found here in order $\lambda^2$, and the divergence in the next order. There is also the more than analogous relationship between the finiteness of the Casimir energy for a dielectric-diamagnetic ball with $\epsilon \mu = 1$, and the finiteness found here when $\lambda^{TE} \lambda^{TM} = 4$: In both cases the divergences separately associated with TE and TM modes cancel.

There are also extremely interesting issues related to surface divergences in the local Casimir energy density, which have been discussed recently by Fulling [29]. His ideas likely will have bearing on understanding the nature of the divergences encountered in these problems.

Evidently, there is much work to be done in understanding the nature of quantum vacuum energy. It would obviously be of great benefit if it would be possible to access these questions experimentally.

Acknowledgments

The author would like to thank Michael Bordag, Ines Cavero-Pelaez, Ricardo Estrada, Steve Fulling, Klaus Kirsten, Kuloth Shajesh, and all the participants of the recent workshop on Quantum Field Theory Under the Influence of External Conditions (QFEXT03) for helpful discussions, and Gabriel Barton for sending me his papers prior to publication. I am grateful to the US Department of Energy for partial financial support of this research.
