Abstract

In this paper, we describe the two different stochastic differential equations representing cholera dynamics. The first stochastic differential equation is formulated by introducing the stochasticity to deterministic model by parametric perturbation technique which is a standard technique in stochastic modeling and the second stochastic differential equation is formulated using transition probabilities. We analyse a stochastic model using suitable Lyapunov function and Itô formula. We state and prove the conditions for global existence, uniqueness of positive solutions, stochastic boundedness, global stability in probability, moment exponential stability, and almost sure convergence. We also carry out numerical simulation using Euler-Maruyama scheme to simulate the sample paths of stochastic differential equations. Our results show that the sample paths are continuous but not differentiable (a property of Wiener process). Also, we compare the numerical simulation results for deterministic and stochastic models. We find that the sample path of $S\dot{I}_R - B$ stochastic differential equations model fluctuates within the solution of the $S\dot{I}_R - B$ ordinary differential equation model. Furthermore, we use extended Kalman filter to estimate the model compartments (states), we find that the state estimates fit the measurements. Maximum likelihood estimation method for estimating the model parameters is also discussed.

Keywords

Stochastic Differential Equations, Stability Condition, Extended Kalman
1. Introduction

It is well known that diseases have impacts on people’s health. Therefore, it is necessary to study the mechanism by which the disease spread, conditions for the disease to have minor or major outbreak and get the knowledge on how to control the diseases such as cholera, Ebola, etc. In this study we are mainly concern with cholera epidemic. Cholera is an infectious disease that causes severe watery diarrhea, which leads to dehydration and even death if untreated. According to WHO report [1], about 1.4 to 4.3 million cases of cholera are reported each year worldwide and more than 140,000 deaths per year are reported due to cholera. As a result of this, several mathematical models have been developed to model cholera epidemics, through these models one can predict the behaviour of the disease and control the particular epidemic. Any epidemic of an infectious disease can be modelled by using either deterministic or stochastic models. The deterministic models are formulated as a system of ordinary different equations and are preferred by many researchers since its analysis is simple compared to stochastic models. However, the shortcomings of deterministic models are: they give less information, rely on the law of large numbers, difficulty to do estimation, when the population is very small it becomes difficult to do analysis and also, experimentally the measured trajectories do not behave as predicted due to some random effects that disturb the system [2].

Due to these limitations of ordinary differential equations in modelling infectious diseases, stochastic modelling of infectious diseases in both heterogeneous and homogeneous population emerged as an alternative to deterministic model and alleviated some of the problems of deterministic models in modelling epidemic diseases. In reality many phenomena in nature are usually affected by stochastic noise and the ordinary differential Equation (ODEs) models ignore the stochastic effects [2]. The stochasticity can be added to the ODEs by including the random terms or elements by parametric perturbation technique. This technique introduces other parameters to the model known as noise intensities.

Many of the models that have been employed in water-borne settings have been deterministic, thus ignoring the possible effects of randomness; see, e.g. [3] [4] [5] [6] [7]. These models incorporate an environmental pathogen component that is the concentration of the vibrios into a SIR (susceptible-infected-recovered) and SIIR (susceptible-symptomatic infected-asymptomatic infected-recovered) epidemic framework. Some of these models only considered compartment I as a single compartment (individuals with severe symptoms only) (e.g. [3] [4] [5] [6]) instead of splitting it into two heterogeneous groups that are symptomatic and asymptomatic infected individuals to study the transmission dynamics of cholera epidemic. Also, some of these models considered only direct transmission of disease i.e., human to human and other models ignored
the feedback loop from infected individuals to the environment reservoir. However, in their studies no stochastic models considered, so as to keep track where the disease is at continuous time and not only at discrete time as shown in their studies.

In [7] they developed deterministic model by extending the work by [6]. The work in [6] considered infected individuals \( I \) as a homogeneous group that is people with severe symptoms like vomiting and diarrhoea. Therefore, [7] divided infected individuals \( I \) into symptomatic infected \( I_s \) and asymptomatic infected \( I_a \), in order to observe the contribution of concentration of Vibrio cholerae in the environment through excretion from each compartment and hence how it leads to the transmission dynamics of cholera epidemic.

In the stochastic modeling of cholera epidemic few papers emphasized on cholera stochastic models. [8] developed a deterministic model and further, extended it stochastic differential equations, the limitations to their paper are: no numerical analysis considered in their paper and compartment \( I \) is considered as single compartment, it could be better to split it into two groups, individuals with severe symptoms (symptomatic infected individuals) and those with mild symptoms (asymptomatic infected individuals) so as to observe the contribution of these two groups to the concentration of Vibrio cholerae through excretion.

[9] [10] developed a simple deterministic and stochastic model to discuss the spread of cholera. In their paper, they described the spread of cholera by modeling the bacteria population in contaminated water and human interaction with the bacteria in the water supply. The limitation to their paper is the absence of enough theoretical and numerical analysis. In [11] proposed a deterministic model that described the interaction among the two types of vibrios and viruses. The deterministic model proposed was further extended to include the random effects and from the stochastic model formulated it indicated that there is always a positive probability of disease extinction within the human host.

In this paper, we extend the deterministic model developed in [7] by formulating an equivalent stochastic differential Equation (SDEs). The formulated stochastic differential Equation (SDEs) models will be analyzed theoretically using suitable Lyapunov functions, Itô formula and some stochastic techniques. Numerical simulation will be carried using Euler-Maruyama scheme and extended Kalman filter. Also, maximum likelihood estimation method will be used to estimate the model parameters.

In the next section, we present a deterministic cholera epidemic model with water treatment, which is a model formulated by [7]. In Section 3, the corresponding two different stochastic models are formulated using parametric perturbation technique and transition probabilities approach. In Section 4, the formulated stochastic differential equations are analyzed by proving the existence and positivity of solutions, stochastic boundedness, global stability in probability, moment exponential stability, and almost sure convergence. In Section 5, the numerical results from the deterministic and stochastic simulations are presented, discussed and compared. In Section 6, we provide a brief discussion to
support our findings. Ultimately, the last section concludes our paper.

2. Cholera Deterministic Model

From the description of the dynamics of cholera as shown in Figure 1, we the following set of ordinary differential equation system as in [7].

\[
\begin{align*}
\frac{dS(t)}{dt} &= bN_c - \frac{\beta B(t)S(t)}{\kappa + B(t)} - \mu S(t), \\
\frac{dI_s(t)}{dt} &= p\frac{\beta B(t)S(t)}{\kappa + B(t)} - (\mu + r_1 + d)I_s(t), \\
\frac{dI_a(t)}{dt} &= q\frac{\beta B(t)S(t)}{\kappa + B(t)} - (\mu + r_2)I_a(t), \\
\frac{dR(t)}{dt} &= r_1I_s(t) + r_2I_a(t) - \mu R(t), \\
\frac{dB(t)}{dt} &= \alpha_1I_s(t) + \alpha_2I_a(t) - (\delta + \phi)B(t),
\end{align*}
\]  

with suitable initial conditions. The total human population is given by

\[N_c = S(t) + I_s(t) + I_a(t) + R(t) .\]

From the model: \(S(t), \ I_s(t), \ I_a(t), \ R(t)\) and \(B(t)\) refer to susceptible individuals, symptomatic infected individuals, asymptomatic infected individuals, recovered individuals and the pathogen concentration in the contaminated environment respectively. The model parameters are described as follows.

\(b\) is the birth rate or recruitment rate, \(\beta\) is rate of exposure to contaminated water, \(\kappa\) is the concentration of Vibrio cholerae in water, \(\alpha_1\) is the contribution

---

**Figure 1.** The interaction of cholera epidemic transmission dynamics between compartments is shown.
of $I_s(t)$ to the population of *Vibrio cholerae* through excretion, $\alpha_z$ is the contribution of $I_a(t)$ to the population of *Vibrio cholerae* through excretion, $d$ death rate due to cholera, $\delta$ death rate of *Vibrio cholerae* due to water treatment, $\phi$ is the mortality rate for bacteria including phage degradation, $r_1$ is the recovery rate of symptomatic infected individuals, $r_2$ is the recovery rate of asymptomatic infected individuals, $p$ is the prob. of new infected from $S(t)$ to be symptomatic, $q$ is the prob. of new infected $S(t)$ to be asymptomatic, $\mu$ is the natural death rate.

The key parameter in epidemiology is the basic reproduction number, which is defined as the average number of secondary infectious cases transmitted by a single primary infectious cases introduced into a whole susceptible population [12]. This parameter is useful because it helps determine whether an infectious disease will spread within the population or not. To compute $R_0$, the next generation matrix approach is used as in [13]. It is obtained by taking the largest (dominant) eigenvalue value (spectral radius) of

$$ R_0 = \left\{ \frac{\alpha \beta \mu p + \alpha z \beta q r_1 + \alpha z \beta p r_2 + \alpha z \beta d q + \alpha z \mu q}{D_n} \right\}_{bN_v}, \quad (2) $$

where $F_i$ is the rate of appearance of new infection in compartment $i$, $\mathcal{V}_i$ is the net transition between compartments, $E_0$ is the disease free equilibrium and $\mathcal{X}_i$ stand for the terms in which the infection is in progression i.e., $I_s(t)$, $I_a(t)$ and $B(t)$ in the model (1). Hence, the basic reproduction number obtained in [7] was as follows:

$$ R_0 = \left\{ \frac{\alpha \beta \mu p + \alpha z \beta q r_1 + \alpha z \beta p r_2 + \alpha z \beta d q + \alpha z \mu q}{D_n} \right\}_{bN_v}, \quad (2) $$

where

$$ D_n = \delta \kappa \mu d + \delta \kappa \mu i^2 + \delta \kappa \mu r_1 + \delta \kappa d r_2 + \delta \kappa m r_2 + \delta \kappa r_1 r_2 + \delta \kappa \mu \phi + \phi \kappa i^2 + \kappa \mu r_1 + \kappa \phi d r_2 + \kappa \mu m r_2 + \kappa \phi r_1 r_2. $$

From Equation (2), when $R_0 < 1$, the highly infectious vibrios will not grow within human host and the environmental vibrios ingested into human body will not cause cholera infection. But when $R_0 > 1$ the human vibrios will grow and persist, and hence leads to human cholera.

### 3. Stochastic Differential Equations

In this section we provide two approaches of formulating stochastic differential equations from the deterministic model (1). These approaches are parametric perturbation Itô SDEs and Itô SDEs from the transition probabilities.

#### 3.1. Parametric Perturbation Itô SDEs

The idea of parametric perturbation is to choose a parameter of interest from the deterministic model and change it to random variable [14] [15]. In this study we introduce the randomness into the model by replacing parameters $\beta$ and $d$ by
\[ \beta \mapsto \beta + \sigma_1 \, dW_1(t) \] and \[ d \mapsto d + \sigma_2 \, dW_2(t) \], where \( W_1 \) and \( W_2 \) are two independent standard Brownian motions with the following properties:

1) \( W_0^1 = 0 \ P \text{-a.s.} \)
2) For all times \( 0 \leq s < t \), the increment \( W_t - W_s \) is normally distributed with zero mean and variance \( t - s \); i.e., \( W_t - W_s \sim N(0, t - s) \),
3) For all times \( 0 < t_1 < t_2 < \cdots < t_n \), the increments \( W_{t_i} - W_{t_{i-1}} \) of the process are independent random variables,
4) All sample paths \( W(\cdot, \omega): [0, \infty) \to \mathbb{R}, \omega \in \Omega \) are continuous \( \mathbb{P} \text{-a.s.} \).

Similarly, \( \sigma_1 \) and \( \sigma_2 \) are real constants, known as the intensities of the stochastic environment.

From the deterministic model (1) we get the following system of stochastic differential equations:

\[
\begin{align*}
\frac{dS(t)}{S(t)} &= \left[ bN_e - \frac{\beta B(t) S(t)}{\kappa + B(t)} - \mu S(t) \right] dt - \frac{\sigma_1 B(t) S(t) \, dW_1(t)}{\kappa + B(t)}, \\
\frac{dI_s(t)}{I_s(t)} &= \left[ \int p \beta B(t) S(t) - \left( \mu + r_1 + d \right) I_s(t) \right] dt - \frac{\sigma_1 p B(t) S(t) \, dW_1(t)}{\kappa + B(t)} - \sigma_2 I_s(t) \, dW_2(t), \\
\frac{dI_a(t)}{I_a(t)} &= \left[ \int q \beta B(t) S(t) - \left( \mu + r_2 \right) I_a(t) \right] dt - \frac{\sigma_2 q B(t) S(t) \, dW_2(t)}{\kappa + B(t)}, \\
dR(t) &= \left[ r_1 I_1(t) + r_2 I_2(t) - \mu R(t) \right] dt, \\
\frac{dB(t)}{B(t)} &= \left[ \alpha_1 I_1(t) + \alpha_2 I_2(t) - (\delta + \phi) B(t) \right] dt,
\end{align*}
\]

with suitable initial conditions. The technique of parameter perturbation introduces another parameters \( \sigma_1 \) and \( \sigma_2 \) in a model.

### 3.2. Itô SDEs with Transition Probabilities

This method was proposed by [16] [17], the stochastic differential equations follow from the diffusion process. The nature of stochastic differential equation to be formulated is in this form:

\[
\frac{dx(t)}{\Delta t} = f(t, x(t); \theta) \frac{\Delta t}{\Delta t} + G(t, x(t); \theta) \, dW(t),
\]

where \( G(t, x(t); \theta) \) is a matrix satisfying \( GG^T = \Sigma \) [16] [17], \( \Sigma \) is the co-variance to order \( \Delta t \), \( \Sigma \Delta t \) is the approximate covariance matrix, \( W(t) \) is the vector of independent Wiener process, \( \theta \) is a vector of parameters and \( f(t, x(t); \theta) \) is the drift part or deterministic part.

From Equation (1) we formulate an equivalent SDEs as

\[
\frac{dx(t)}{\Delta t} = F(t, x(t); \theta) \frac{\Delta t}{\Delta t} + G(t, x(t); \theta) \, dW(t),
\]

where \( F = \mathbb{E}[\Delta x] / \Delta t \) and \( G = \sqrt{\mathbb{E}[\Delta x (\Delta x)^T] / \Delta t} \). Clearly, \( x(t) \) is an Itô process,
such that \( x(t) = [x_1, x_2, x_3, x_4]^T \). Then, \( x_1, x_2, x_3, x_4 \), corresponds to the number of individuals \( S(t), I_1(t), I_2(t), R(t) \in [0, N_c] \) respectively and \( B(t) \) the *Vibrio cholerae* concentration in the environment. However, \( B(t) \) is not a compartment occupancy as the other one are so its transition is not considered in the formulation of transitions.

In order to find the expectation \( E[\Delta x] \) and covariance matrix \( \Sigma \), we need to consider the transition probabilities as stated in Table 1. The transition probabilities are formulated from Equation (1). From Table 1, the expectation and variance co-variance matrix are computed as follows:

\[
E[\Delta x] = \sum_{j=1}^{10} P_j (\Delta x_j) = P_1 \Delta x_1 + P_2 \Delta x_2 + P_3 \Delta x_3 + P_4 \Delta x_4 + P_5 \Delta x_5 + P_6 \Delta x_6 + P_7 \Delta x_7 + P_8 \Delta x_8 + P_9 \Delta x_9 + P_{10} \Delta x_{10}.
\]

On substituting the values of \( P_j, \Delta x_j \) and \( [x_1, x_2, x_3, x_4]^T = [S(t), I_1(t), I_2(t), R(t)]^T \) to Equation (6), we get

\[
E[\Delta x] = \begin{bmatrix}
    bN_c - \frac{\beta B(t)S(t)}{\kappa + B(t)} - \mu S(t) \\
    \frac{p \beta B(t)S(t)}{\kappa + B(t)} -(\mu + r_1 + d) I_1(t) \\
    \frac{q \beta B(t)S(t)}{\kappa + B(t)} -(\mu + r_2) I_2(t) \\
    r_1 I_1(t) + r_2 I_2(t) - \mu R(t)
\end{bmatrix} dt
\]

and the co-variance matrix is given by

**Table 1.** Possible changes in the process for the \( SI_{I_2}R-B \) model.

| Possible changes | Probabilities |
|------------------|---------------|
| \( \Delta x_1 = [1,0,0,0]^T \) | \( P_1 = bN_c, M \) |
| \( \Delta x_2 = [-1,1,0,0]^T \) | \( P_2 = \frac{p \beta B x_2}{\kappa + B} M \) |
| \( \Delta x_3 = [-1,0,1,0]^T \) | \( P_3 = \frac{q \beta B x_3}{\kappa + B} M \) |
| \( \Delta x_4 = [0,-1,0,0]^T \) | \( P_4 = dx, M \) |
| \( \Delta x_5 = [-1,0,0,0]^T \) | \( P_5 = \mu x, M \) |
| \( \Delta x_6 = [0,-1,0,1]^T \) | \( P_6 = r x, M \) |
| \( \Delta x_7 = [0,-1,0,0]^T \) | \( P_7 = \mu x, M \) |
| \( \Delta x_8 = [0,0,-1,0]^T \) | \( P_8 = r x, M \) |
| \( \Delta x_9 = [0,0,0,-1]^T \) | \( P_9 = r x, M \) |
| \( \Delta x_{10} = [0,0,0,-1]^T \) | \( P_{10} = \mu x, M \) |
Also, by substituting the values of $p_i$, $\Delta x_i$, and
$[x_1, x_2, x_3, x_4] = [S(t), I_s(t), I_a(t), R(t)]$ to Equation (7), we get
\[ E\left[\Delta x(\Delta x)^T\right] = \sum_{i=1}^{10} P_i(\Delta x_i)(\Delta x_i)^T \]
\[ = P_1(\Delta x_1)(\Delta x_1)^T + P_2(\Delta x_2)(\Delta x_2)^T + P_3(\Delta x_3)(\Delta x_3)^T + P_4(\Delta x_4)(\Delta x_4)^T \]
\[ + P_5(\Delta x_5)(\Delta x_5)^T + P_6(\Delta x_6)(\Delta x_6)^T + P_7(\Delta x_7)(\Delta x_7)^T \]
\[ + P_8(\Delta x_8)(\Delta x_8)^T + P_9(\Delta x_9)(\Delta x_9)^T + P_{10}(\Delta x_{10})(\Delta x_{10})^T. \]

Also, the Itô stochastic differential equation, where global Lipschitz conditions are satisfied to ensure the existence and uniqueness of strong solution, can be written as in Equation (4) as found in [14]. Hence by Equation (5), the Itô stochastic differential equations become:
\[ \text{dx}(t) = \begin{bmatrix}
\frac{bN_e - \beta B(t) S(t)}{\kappa + B(t)} - \mu S(t) \\
\frac{p \beta B(t) S(t)}{\kappa + B(t)} - (\mu + r_i + d) I_s(t) \\
\frac{q \beta B(t) S(t)}{\kappa + B(t)} - (\mu + r_a) I_a(t) \\
r_i I_s(t) + r_a I_a(t) + \mu R(t)
\end{bmatrix} dt \]
4. Analysis of Parametric Perturbation Itô Stochastic Differential Equation Model

In this paper, unless otherwise stated, we let \( \Omega, \mathcal{F}, \{\mathcal{F}_t\}, \mathbb{P} \) be a complete filtered probability space, with \( \{\mathcal{F}_t\}_{t \geq 0} \) satisfying the usual conditions (i.e., increasing and right continuous also \( \mathcal{F}_0 \) contains all \( \mathbb{P} \)-null sets). Let

\[
\Delta = \left\{ x \in \mathbb{R}^4 : x_1 + x_2 + x_3 + x_4 < \frac{bN_x}{\mu} \right\},
\]

where

\[
x_1 = S(t), x_2 = I_s(t), x_3 = I_a(t), x_4 = R(t).
\]

4.1. Global Existence and Uniqueness of Positive Solutions

Before proving the existence and uniqueness of positive solutions, let us state the conditions that guarantee the existence and uniqueness of solution of Equation (4).

**Lemma 1.** Assume that there exist two positive constants \( \hat{K} \) and \( K \) such that

1) (Lipschitz condition) for all \( x, y \in \mathbb{R}^n \) and \( t \in [t_0, T] \)

\[
\left| f(x, t) - f(y, t) \right|^2 \leq \hat{K} \left| x - y \right|^2.
\]

2) (Linear growth condition) for all \( (x, t) \in \mathbb{R}^n \times [t_0, T] \)

\[
\left| f(x, t) \right|^2 \leq K \left( 1 + |x|^2 \right).
\]

**Theorem 1.** For any initial value \( (S(0), I_s(0), I_a(0), R(0), B(0)) \in \mathbb{R}_+^5 \), there is a unique solution \( x(t) = (S(t), I_s(t), I_a(t), R(t), B(t)) \) to system (3) for all \( t \geq 0 \), and the solution will remain in \( \mathbb{R}_+^5 \) with the probability 1, namely \( x(t) \in \mathbb{R}_+^5 \), for all \( t \geq 0 \) almost surely.

**Proof.** Since the coefficients of system (3) satisfy the local Lipschitz condition, then for initial values \( (S(0), I_s(0), I_a(0), R(0), B(0)) \in \mathbb{R}_+^5 \), there is unique local solution \( S(t), I_s(t), I_a(t), R(t), B(t) \) on \([0, \nu_c]\), where \( \nu_c \) is the first hitting time or explosion time. In order to prove that the solution is global and positive, we need to show that \( \nu_c = \infty \) a.s. Let \( k_0 > 0 \) be sufficiently large so that \( S(0), I_s(0), I_a(0), R(0), B(0) \) remain within the interval \( \left[ \frac{1}{k_0}, k_0 \right] \). For
integer \( k \geq k_0 \). Let \( \nu_k : \Omega \mapsto [0, \infty) \) be any random variable (taking eventually infinite value) on a filtered probability space \( (\Omega, \mathcal{F}, \{\mathcal{F}_t\}, \mathbb{P}) \). We say that \( \nu_k \) is a stopping time for filtration \( \mathcal{F}_t \) if at each (deterministic) time \( t \geq 0 \), the event \([\nu_k \leq t]\) is known in \( \mathcal{F}_t \). In this study we define

\[
\nu_k = \inf \left\{ t \in [0, \nu_k) : x_i(t) \notin \left( \frac{1}{k}, k \right) \text{ for some } i, 1 \leq i \leq 5 \right\}
\]

Let \( \emptyset \) be empty set then the inf \( \emptyset = \infty \). By definition \( \nu_k \) increases as \( k \to \infty \). Let \( \nu_\infty = \lim_{k \to \infty} \nu_k \), then \( \nu_\infty \leq \nu_k \) a.s. We need to show that \( \nu_\infty = \infty \) a.s. Then \( \nu_\infty = \infty \) and \( x(t) \in \mathbb{R}^5 \). If this statement is false we say that, there exist \( \varepsilon \in (0, 1) \) and a constant \( T > 0 \), such that \( \mathbb{P}\{\nu_\infty \leq T\} > \varepsilon \). As a consequence to this, there exist an integer \( k_i > k_0 \) such that

\[
\mathbb{P}\{\nu_k \leq T\} \geq \varepsilon, \quad \forall k \geq k_i
\]

For \( t \leq \nu_k \) and at each \( k \),

\[
d(S + I_s + I_a + R) = \left[ \Lambda - (S + I_s + I_a + R)\mu - dI_s \right]dt
\]

\[
\leq \left[ \Lambda - (S + I_s + I_a + R)\mu \right]dt,
\]

where \( \Lambda = \frac{bN_s}{\mu} \). Then

\[
S(t) + I_s(t) + I_a(t) + R(t) \leq \begin{cases} \frac{\Lambda}{\mu} & \text{if } N_0 \leq \frac{\Lambda}{\mu} \\ N_0 & \text{if } N_0 \geq \frac{\Lambda}{\mu} \end{cases} =: M_i,
\]

where

\[
N_0 = S(0) + I_s(0) + I_a(0) + R(0),
\]

and

\[
M_i = \max \left[ \frac{\Lambda}{\mu}, N_0 \right].
\]

Define now \( C^{1,2} \) the Lyapunov function \( V : \mathbb{R}^5_+ \to \mathbb{R}_+ \) by

\[
V(S, I_s, I_a, R, B) = (S - 1 - \ln S) + (I_s - 1 - \ln I_s) + (I_a - 1 - \ln I_a) + (R - 1 - \ln R) + (B - 1 - \ln B),
\]

and \( S(t), I_s(t), I_a(t), R(t), B(t) \in \Omega \). Then \( V(x(t), t) \) is an Itô stochastic process with the SDEs given by

\[
dV(x(t), t) = \left[ V_s(x(t), t) + V_a(x(t), t)f(t) + \frac{1}{2} \text{tr} \left( g^T(t) V_{aa}(x(t), t) g(t) \right) \right]dt
\]

\[
+ V_s(x(t), t)g(t)dW(t),
\]

which becomes

\[
dV(x(t), t) = LV dt + V_s(x(t), t)g(t)dW(t),
\]

where
\[ LV = \left(1 - \frac{1}{S}\right) \Lambda - \frac{\beta BS}{\kappa + B} \mu S + \left(1 - \frac{1}{I_s}\right) p \frac{\beta BS}{\kappa + B} (\mu + r_1 + d) I_s \\
+ \left(1 - \frac{1}{I_a}\right) q \frac{\beta BS}{\kappa + B} - (\mu + r_2) I_a + \left(1 - \frac{1}{R}\right) r_1 I_s + r_2 I_a - \mu R \\
+ \left(1 - \frac{1}{B}\right) \alpha_1 I_s + \alpha_2 I_a - (\delta + \phi) B + \frac{1}{2 S^2} \left[ \frac{\sigma^2 B^2 S^2}{(\kappa + B)^2} \right] dt \\
+ \frac{1}{2 I_s^2} \left[ \frac{\sigma^2 p^2 B^2 S^2}{(\kappa + B)^2} + \sigma^2 I_s^2 \right] dt + \frac{1}{2 I_a^2} \left[ \frac{\sigma^2 q^2 B^2 S^2}{(\kappa + B)^2} \right] dt \]

Hence

\[ LV \leq \Lambda + \frac{\beta B}{\kappa + B} + \mu + \frac{p \beta BS}{\kappa + B} + \mu + r_1 + d + \frac{q \beta BS}{\kappa + B} + \mu + r_2 + r_1 I_s \\
+ r_2 I_a + \mu + \alpha_1 I_s + \alpha_2 I_a + \delta + \phi + \frac{\sigma^2 B^2}{2 (\kappa + B)^2} + \frac{\sigma^2 p^2 B^2 S^2}{2 I_s^2 (\kappa + B)^2} (15) \]

\[ \frac{\sigma^2}{2} + \frac{S^2}{2 I_s^2 (\kappa + B)^2} \]

From \( M = \max \left[ \frac{\Lambda}{\mu}, N_0 \right] \), it follows that

\[ LV \leq \Lambda + \left( \frac{p \beta B}{\kappa + B} + \frac{q \beta B}{\kappa + B} + r_1 + r_2 + \alpha_1 + \alpha_2 \right) M + \frac{\beta B}{\kappa + B} + \delta + \phi \\
+ \frac{\sigma^2 B^2}{2 (\kappa + B)^2} + \frac{\sigma^2 p^2 B^2 M^2}{2 I_s^2 (\kappa + B)^2} + \frac{\sigma^2}{2} + 4 \mu + r_2 + r_1 + d + \frac{M^2 \sigma^2 q^2 B^2}{2 I_a^2 (\kappa + B)^2} (16) \]

\[ := K_s \]

where \( K \) is a positive constant independent of variables \( S, I_s, I_a, R, B \) and time \( t \). Then we obtain

\[ dV \leq K_s dt - \left( \frac{S}{I_s} - \frac{1}{p} \right) \frac{\sigma_1 p B d V_1(t)}{\kappa + B} - \frac{S}{I_a} \frac{\sigma_2 q B d V_2(t)}{\kappa + B} - \sigma_3 dV_3(t), (17) \]

let \( V_k \wedge T = \min \{ V_k, T \} \). Introduce integral to Equation (17)

\[ \int_0^{V_k \wedge T} dV = \int_0^{V_k \wedge T} \left( \frac{S}{I_s} - \frac{1}{p} \right) \frac{\sigma_1 p B d V_1(s)}{\kappa + B} - \frac{S}{I_a} \frac{\sigma_2 q B d V_2(s)}{\kappa + B} - \sigma_3 dV_3(s) \]

\[ = \int_0^{V_k \wedge T} \kappa ds - \int_0^{V_k \wedge T} \left( \frac{S}{I_s} - \frac{1}{p} \right) \frac{\sigma_1 p B d V_1(s)}{\kappa + B} - \frac{S}{I_a} \frac{\sigma_2 q B d V_2(s)}{\kappa + B} (18) \]

Introducing the expectation to Equation (18) and by the Gronwall inequality, leads to

\[ \mathbb{E} \left[ V \left( S(V_k \wedge T), I_s(V_k \wedge T), I_a(V_k \wedge T), I_s(V_k \wedge T), B(V_k \wedge T) \right) \right] \leq C + K T, \]

where \( C = V (S(0), I_s(0), I_a(0), R(0), B(0)) \). Since the mean of stochastic integral equals zero [18]. Then let \( \Omega_k = \{ V_k \leq T \}, \forall k \geq k_1 \) from inequality (9), we have \( \mathbb{P} (\Omega_k) \geq \epsilon \). Then for all \( \omega \in \Omega_k \), there must exist at least one of
which can take either $\frac{1}{k}$ or $k$. Hence we have

$$V(S(v,T), I_s(v,T), I_a(v,T), R(v,T), B(v,T)) \geq \left[ k - 1 - \log(k) \right] \land \left[ \frac{1}{k} - 1 - \log\left( \frac{1}{k} \right) \right].$$

(20)

again define the indicator function on $\Omega_k$ denoted by $\mathcal{I}_k$ be defined for all $\omega \in \Omega_k$ by

$$\mathcal{I}_k(\omega) = \begin{cases} 1 & \text{if } \omega \in \Omega_k \\ 0 & \text{otherwise} \end{cases}$$

From Equation (19) and by Bienayme Chebyshev inequality we have

$$C + \mathbb{E} \mathcal{I}_k S(v_T), I_s(v_T), I_a(v_T), R(v_T), B(v_T)) \geq \epsilon \left[ k - 1 - \log(k) \right] \land \left[ \frac{1}{k} - 1 - \log\left( \frac{1}{k} \right) \right].$$

(21)

when $k \to +\infty$, this leads to contradiction as

$$\infty > V(S(0), I_s(0), I_a(0), R(0), B(0)) + \mathbb{E}T = \infty$$

Therefore, we conclude that for the solution $S(t), I_s(t), I_a(t), R(t), B(t)$ of cholera model not to explode at finite time with probability 1, we need to have $\nu_\infty = \infty$ a.s. This completes the proof. □

Theorem 1 shows that the solution of model (3) will remain in $\mathbb{R}_+^5$. Next, we give the definition of stochastic ultimate boundedness [19], which is very important in population dynamics.

**Definition 1.** The solution $x(t) = (S(t), I_s(t), I_a(t), R(t), B(t))$ of model (3) are said to be stochastically ultimately bounded, if for any $\epsilon \in (0,1)$, there is a positive constant $\delta = \delta(\epsilon)$, such that for any initial value $x_0 = (S(0), I_s(0), I_a(0), R(0), B(0)) \in \mathbb{R}_+^5$, the solution $x(t)$ to Equation (3) has a property that

$$\limsup_{t \to \infty} \mathbb{P}\left( \sqrt{x(t)} > \delta \right) < \epsilon.$$

**Theorem 2.** The solutions of system (3) are stochastically ultimately bounded for any initial value $x_0 \in \mathbb{R}_+^5$.

**Proof.** From Theorem 1, we showed that $S(t), I_s(t), I_a(t), R(t), B(t)$ remain in $\mathbb{R}_+^5$, for all $t \geq 0$ almost surely.

Let $V_1, V_2$ and $V_3$ be lyapunov functions stated as

$$V_1 = \epsilon S^\theta, \quad V_2 = \epsilon I_s^\theta, \quad V_3 = \epsilon I_a^\theta \quad \text{where } \theta > 1.$$  

(22)

Taking their derivatives with respect to $\theta$ we get

$$V_1'(\theta) = \frac{\partial \epsilon S^\theta}{S}, \quad V_2'(\theta) = \frac{\partial \epsilon I_s^\theta}{I_s} \quad \text{and} \quad V_3'(\theta) = \frac{\partial \epsilon I_a^\theta}{I_a}.$$  

(23)

Using Itô formula we get

$$dV_1 = LV_1dt - \sigma \theta B \epsilon S^\theta d\mathcal{W}(t).$$
\[ dV_2 = LV_2 dt - \frac{\sigma_1 p \theta B \epsilon S^0}{\kappa + B} dV_1 (t) + \frac{\sigma_1 \theta e^I_2 dV_1 (t)}{\kappa + B}, \] 
\[ dV_3 = LV_3 dt - \frac{\sigma_2 q \theta B \epsilon S^0}{\kappa + B} dV_1 (t), \]

but
\[ LV_1 = \frac{\partial V_1}{\partial t} + V_{10} f (t) + \frac{1}{2} \text{trace} \left( g_1^T (t) V_{100} g_1 (t) \right), \]
\[ LV_2 = \frac{\partial V_2}{\partial t} + V_{20} f (t) + \frac{1}{2} \text{trace} \left( g_2^T (t) V_{200} g_2 (t) \right), \]
\[ LV_3 = \frac{\partial V_3}{\partial t} + V_{30} f (t) + \frac{1}{2} \text{trace} \left( g_3^T (t) V_{300} g_1 (t) \right), \] 

where
\[ V_{100} = \frac{\theta (\theta - 1) e^2 S^0}{S^2}, \]
\[ V_{200} = \frac{\theta (\theta - 1) e^2 l^2}{I_s^2}, \]
\[ V_{300} = \frac{\theta (\theta - 1) e^2 l^2}{I_a^2}, \]

\[ g_1 (t) = \left[ -\sigma_1 B S \right] / \left[ \kappa + B \right], g_2 (t) = \left[ \sigma_1 p B S \right] / \left[ \kappa + B \right], g_3 (t) = \left[ \sigma_2 q B S \right] / \left[ \kappa + B \right]. \]

Therefore
\[ LV_1 = e^2 S^0 \left[ 1 + \theta \left( \frac{\Lambda}{S} \right) \frac{\beta B}{\kappa + B} - \mu \right] + \frac{1}{2} \theta (\theta - 1) e^2 S^0 \sigma_1^2 B^2 \]
\[ + \frac{1}{2} \sigma_2^2 \theta (\theta - 1) e^2 l^2, \]
\[ LV_2 = e^2 l_s^2 \left[ 1 + \theta \left( \frac{p \beta B S}{l_s (\kappa + B)} - \mu - r_1 - d \right) \right] + \frac{1}{2} \sigma_1^2 \theta (\theta - 1) e^2 l_s^2 \]
\[ + \frac{1}{2} \sigma_2^2 \theta (\theta - 1) e^2 l_s^2, \]
\[ LV_3 = e^2 l_a^2 \left[ 1 + \theta \left( \frac{q \beta B S}{l_a (\kappa + B)} - \mu - r_2 \right) \right] + \frac{1}{2} \sigma_1^2 \theta (\theta - 1) e^2 l_a^2 \]
\[ + \frac{1}{2} \sigma_2^2 \theta (\theta - 1) e^2 l_a^2. \]

There exists positive constants \( K_1, K_2 \) and \( K_3 \) such that
\[ LV_1 < K_1 e^2, \quad LV_2 < K_2 e^2, \quad \text{and} \quad LV_3 < K_3 e^2. \] 

It follows that
\[ \mathbb{E} \left( S^0 (t) \right) - \mathbb{E} \left( S^0 (0) \right) \leq K_1, \quad \mathbb{E} \left( l_s^0 (t) \right) - \mathbb{E} \left( l_s^0 (0) \right) \leq K_2 \]
\[ \text{and} \quad \mathbb{E} \left( l_a^0 (t) \right) - \mathbb{E} \left( l_a^0 (0) \right) \leq K_3. \] 

Then
\[ \limsup_{t \to \infty} \mathbb{E} \left[ S^0 (t) \right] \leq K_1 < \infty, \quad \limsup_{t \to \infty} \mathbb{E} \left[ l_s^0 (t) \right] \leq K_2 < \infty \]
\[ \text{and} \quad \limsup_{t \to \infty} \mathbb{E} \left[ l_a^0 (t) \right] \leq K_3 < \infty. \]

For \( x(t) = (S(t), l_s(t), l_a(t)) \in \mathbb{R}_+^3 \) and consider the case of \( 0 < \theta < 3 \).

Then from the holder inequality we have
\[
\left| x(t) \right|^p = (S^2(t) + I^2_s(t) + I^2_u(t))^\theta \leq \left( 3^\theta \max \left\{ S^\theta(t), I^\theta_s(t), I^\theta_u(t) \right\} \right)^2 \leq 3^2 \left\{ S^\theta(t) + I^\theta_s(t) + I^\theta_u(t) \right\}
\]

(32)

consequently we have

\[
\limsup_{t \to \infty} E \left| x(t) \right|^\theta \leq 3^2 K_4,
\]

(33)

where \( K_4 > 0 \) is a suitable constant.

There exists a positive constants \( \delta_1 \) such that

\[
\limsup_{t \to \infty} \sqrt{\frac{\left| x(t) \right|^\theta}{\theta}} \leq \delta_1.
\]

Given \( \epsilon > 0 \) and let \( \delta = \frac{\delta_1^2}{\epsilon^2} \), then by Bienayme Chebyshev inequality

\[
P\left( \left| x(t) \right| > \delta \right) \leq \frac{E \left| x(t) \right|^\theta}{\delta^2} = \epsilon.
\]

Hence

\[
\limsup_{t \to \infty} P\left( \left| x(t) \right| > \delta \right) \leq \frac{\delta_1}{\sqrt{\epsilon}} = \epsilon.
\]

This completes the proof as required. \( \square \)

4.2. Moment Exponential Stability

The moment exponential stability of the equilibrium solutions of stochastic differential Equation (3) are established from the idea of Lyapunov function [20].

**Lemma 2.** Consider a function \( C^{1,2} \left( \mathbb{R}^n \times [t, \infty); \mathbb{R}_+ \right) \) satisfying these inequalities:

\[
M_1 \left| x \right|^p \leq V(x,t) \leq M_2 \left| x \right|^p
\]

and

\[
LV(x,t) \leq -M_3 \left| x \right|^p, \quad t \geq 0, \forall (x,t) \in \mathbb{R}^n \times [t, \infty]
\]

where \( M_1, M_2, M_3 \) and \( p \) are positive constants. Then the equilibrium solution of Equation (3) is \( p \)th moment exponentially stable. When \( p = 2 \), it is usually said to be exponentially stable in mean square and the DFE is globally asymptotically stable.

**Lemma 3.** When \( p \geq 2 \) and \( x,y,\epsilon > 0 \). Then

\[
x^{p-1}y \leq \frac{(p-1)cx^p}{p} + \frac{1}{p}e^{\frac{1}{p}}y^p \quad \text{and} \quad x^{p-2}y^2 \leq \frac{(p-2)cx^p}{p} + \frac{2}{p}y^p e^{\frac{(2-p)}{2}}.
\]

**Theorem 3.** If \( R_0 < 1 \) and \( p \geq 2 \), the disease free equilibrium of the model system (3) is \( p \)th moment exponentially stable in \( \Delta \).

**Proof.** Given that \( (S(0), I_s(0), I_u(0), R(0), B(0)) \in \Delta \), as from Theorem 1 the solution of the system remains in \( \Delta \). Set \( p \geq 2 \), then consider Lyapunov function \( V = \lambda_1 \left( \frac{\Delta}{\mu} - S \right)^p + \frac{I^p_s}{p} + \lambda_2 I^p_u + \lambda_3 R^p + \lambda_4 B^p \), we have
\[ LV = -\lambda_b p A \left( \frac{\Lambda}{\mu} - S \right)^{p-1} + \frac{\lambda_b p B S \left( \frac{\Lambda}{\mu} - S \right)}{\kappa + B} + \frac{\lambda_b p A \left( \frac{\Lambda}{\mu} - S \right)^{p-1}}{\mu S} \]

\[ + \frac{1}{2} \lambda_b p (p-1) \frac{\Lambda}{\mu} S^{p-1} \alpha_i S_i \left( \frac{\Lambda}{\mu} - S \right)^{p-1} + I^p \left( \frac{p B S}{\kappa + B} - (\mu + r_i + d) I \right) \]

\[ + \frac{1}{2} (p-1) I^p \left( \frac{\Lambda}{\mu} S^{p-1} \alpha_i S_i \left( \frac{\Lambda}{\mu} - S \right)^{p-1} + \frac{1}{2} \sigma_i^2 (p-1) I \right) + \lambda_b p I^p \left( \frac{q B S}{\kappa + B} - (\mu + r_i) I \right) \]

\[ + \lambda_b p R^{p-1} \left( r_i I + r_i I - \mu R \right) + \lambda_b p B^{p-1} \left( \alpha_i I + \alpha_i I - \delta B - \phi B \right) \]

\[ + \frac{1}{2} \lambda_b p (p-1) I^p \left( \frac{\sigma_i^2 q B^2 S^2}{(\kappa + B)^2} \right) . \]

In $\Delta$, we have $S(0), I_x(0), I_z(0), R(0), B(0) \in \left( \frac{\Lambda}{\mu}, 0, 0, 0, 0 \right)$, such that $S \leq \frac{B}{\kappa + B}$, then from the fact that $\frac{B}{\kappa + B} \leq 1$, as $B \in [0,1]$, there exists $\eta \in [0,1]$ such that $\frac{\eta A^2}{\mu^2} (x^2 + y^2) \leq S^2 x^{p-1} y^2$, Then $LV$ becomes

\[ LV \leq -\lambda_b p A \left( \frac{\Lambda}{\mu} - S \right)^{p-1} + \frac{B}{\kappa + B} \lambda_b p A \left( \frac{\Lambda}{\mu} - S \right)^{p-1} \]

\[ + \frac{1}{2} \lambda_b p (p-1) \eta \sigma_i^2 \frac{\Lambda}{\mu} S^{p-1} \alpha_i S_i \left( \frac{\Lambda}{\mu} - S \right)^{p-1} + \frac{1}{2} \sigma_i^2 (p-1) I \leq \frac{\lambda_b p (p-1)}{\mu^2} \eta \sigma_i^2 q B^2 S^2 \]

\[ (35) \]

\[ (36) \]

Applying the idea of Lemma 3, we can formulate some of the inequalities as follows

\[ I_x R^{p-1} \leq \frac{p-1}{p} e^{\mu R} + \frac{1}{p} e^{\mu^2 R} I, \]

\[ I^2 \left( \frac{A}{\mu} - S \right)^{p-1} \leq \frac{p-2}{p} e^{\mu S} + \frac{2}{p} e^{2-\mu} I, \]

\[ N_x \left( \frac{A}{\mu} - S \right)^{p-1} \leq \frac{p-1}{p} e^{\mu S} + \frac{1}{p} e^{\mu^2 N}. \]

On substituting these inequalities in Equation (19), we get

\[ LV \leq -\lambda_b (p-1) e^{\mu S} + \frac{\lambda_b}{\mu} \lambda_b p (p-1) e^{\mu S} \]

\[ + \frac{1}{2} \lambda_b (p-1) \left( p-2 \right) \eta \sigma_i^2 \frac{B^2}{\mu^2} e^{\mu S} + \frac{p^2}{2p} (p-1) (p-2) \eta \sigma_i^2 \frac{B^2}{\mu^2} e^{\mu S} \]

\[ - \left( \mu + r_i + d \right) \frac{1}{2} \lambda_b (p-1) \sigma_i^2 \left( \mu + r_i + d \right) I + \lambda_b (p-1) \phi \mu R + \lambda_b (p-1) \gamma c R \]

\[ + \lambda_b \alpha_i (p-1) \epsilon B + \lambda_b \alpha_i (p-1) \epsilon B + \frac{p_b}{p} (p-1) \beta \mu c I, \]
+ \lambda_q(p-1)\beta \frac{\Lambda}{\mu} e I^p_s - \lambda_p(p+2)I^p_s - \lambda_4 \mu p R^p
\]

- \lambda_p(\delta + \phi) B^p + \frac{1}{2} \lambda_q(p-1)(p-2)\eta \sigma^2 q^2 \frac{b^2}{\mu^2} \eta \left( \frac{\Lambda}{\mu} - S \right)^p
\]

+ \frac{1}{2p} (p-1)(p-2)\eta p^2 \sigma^2 \frac{b^2}{\mu} e I^p_s + \lambda_q \eta e^{1-p} I^p_s + \lambda_4 r_4 e^{1-p} I^p_s
\]

+ \lambda_3 \alpha e^{1-p} I^p_s + \lambda_2 \alpha e^{1-p} I^p_s.
\]

Hence
\[
L^V \leq - \left[ \mu + r_1 + d - \frac{1}{2}(p-1)\sigma^2 + \frac{P}{p} (p-1)\beta \frac{\Lambda}{\mu} e
\right]
\]

\[
- \frac{1}{2p} (p-1)(p-2)\eta p^2 \sigma^2 \frac{b^2}{\mu^2} e - \lambda_3 r_4 e^{1-p} - \lambda_3 \alpha e^{1-p} \right] I^p_s
\]

\[
- \left[ r_1(p-1) + r_2(p-1) + \mu p \right] \lambda_q e R^p
\]

\[
- \left[ p(\delta + \phi) + \alpha_1(p-1) - \alpha_2(1-p) \right] \lambda_p B^p
\]

\[
- \left[ (p-1) \beta e \frac{q}{\mu} + p(\mu + r_2) \right] \lambda_1 - \lambda_3 r_4 e^{1-p} - \lambda_3 \alpha e^{1-p} \right] I^p_s
\]

\[
- \left[ - (\mu + \beta) \frac{b}{\mu} - \frac{1}{2} (p-2) \eta \sigma^2 \frac{b^2}{\mu^2} - F_1 \right] \lambda_1(p-1) e \left( \frac{\Lambda}{\mu} - S \right)^p
\]

\[
- \left[ \lambda_3 e^{1-p} - (\beta + \mu) \frac{b}{\mu} e^{1-p} \lambda_1 - (p-1) \eta \sigma^2 \frac{b^2}{\mu^2} \eta \frac{2^{2-p}}{\lambda_1} \right]
\]

\[
- \left[ \frac{p_1}{p} \beta \frac{b}{\mu} e^{1-p} - \frac{p-1}{p} \eta p^2 \sigma^2 \frac{b^2}{\mu^2} \eta \frac{2^{2-p}}{\lambda_1} - F_2 \right] N^p_e,
\]

where
\[
F_1 = \frac{p^2}{2p \mu^2} (p-2) \eta \sigma^2 \frac{b^2}{\mu^2} + \frac{\lambda_3(p-2)\eta \sigma^2 q^2 \frac{b^2}{\mu^2}}{2\lambda_1} \text{ and}
\]

\[
F_2 = \lambda_3 q \beta e^{1-p} + \lambda_3 (p-1) \eta \sigma^2 q^2 \frac{b^2}{\mu^2} \eta \frac{2^{2-p}}{\lambda_1} \text{. If we choose } \epsilon \text{ sufficiently very small, then we can choose } \lambda_1, \lambda_2, \lambda_3, \lambda_4, \lambda_5 \text{ positive such that the coefficients}
\]

\[
\left( \frac{\Lambda}{\mu} - S \right)^p, I^p_s, \epsilon R^p, B^p, N^p_e \text{ become negative.}
\]

Hence, according to Lemma 2 the proof is complete. □

4.3. Almost Sure Convergence

**Theorem 4** If \( R_0 \in (0, 1) \), then \( I(t), I_s(t), R(t) \) converge almost surely exponentially to \( (0, 0, 0) \).

**Proof.** Let \( (S(t), I(t), I_s(t), R(t)) \in \Delta \). As \( R_0 \in (0, 1) \), define the lyapunov function as \( V(I, I_s, R) = \ln(I(t) + I_s(t) + wR(t)) \), such that \( w > 0 \). Using Itô formula we get

\[
\int_0^T \frac{\lambda}{\mu} e I_s d\mu - \int_0^T \lambda_3 \alpha e^{1-p} I_s d\mu
\]

\[
- \int_0^T \lambda_3 r_4 e^{1-p} I_s d\mu - \int_0^T \lambda_3 \alpha e^{1-p} I_s d\mu
\]
\[
\begin{align*}
\frac{dV}{I_y(t)+I_u(t)+wR(t)} &= \frac{1}{\kappa+B} \left[ \frac{\beta BS}{\kappa+B} \left( \mu + r_1 + d \right) I_y - \left( \mu + r_2 \right) I_u \right] \\
&+ q \frac{\beta BS}{\kappa+B} \left( \mu + r_2 \right) I_u + w \left( r_1 I_y + r_2 I_u - \mu R \right) \\
&- \frac{1}{2 \left( I_y(t)+I_u(t)+wR(t) \right)^2} \left[ \frac{\sigma^2 p^2 B^2 S^2}{\kappa+B} + \frac{\sigma^2 q^2 B^2 S^2}{\kappa+B} \right] \\
&\quad \times \left( I_y(t)+I_u(t)+wR(t) \right) \\
&+ \frac{\sigma q BSdV(t)}{I_y(t)+I_u(t)+wR(t)} + \frac{\sigma q BSdV(t)}{(\kappa+B) I_y(t)+I_u(t)+wR(t)} \\
&+ \frac{\sigma p BSdV(t)}{(\kappa+B) I_y(t)+I_u(t)+wR(t)} + \frac{\sigma q BSdV(t)}{(\kappa+B) I_y(t)+I_u(t)+wR(t)}.
\end{align*}
\]

But \( p + q = 1 \), also by dropping some of the negative terms in Equation (40) we obtain

\[
\begin{align*}
\frac{dV}{I_y(t)+I_u(t)+wR(t)} &= \frac{1}{\kappa+B} \left[ \frac{\beta BS}{\kappa+B} \left( \mu + r_1 + d \right) I_y - \left( \mu + r_2 \right) I_u \right] \\
&+ w \left( r_1 I_y + r_2 I_u - \mu R \right) \\
&- \frac{1}{2 \left( I_y(t)+I_u(t)+wR(t) \right)^2} \left[ \frac{\sigma^2 p^2 B^2 S^2}{\kappa+B} + \frac{\sigma^2 q^2 B^2 S^2}{\kappa+B} \right] \\
&\quad \times \left( I_y(t)+I_u(t)+wR(t) \right) \\
&+ \frac{\sigma p BSdV(t)}{(\kappa+B) I_y(t)+I_u(t)+wR(t)} + \frac{\sigma q BSdV(t)}{(\kappa+B) I_y(t)+I_u(t)+wR(t)} \\
&+ \frac{\sigma q BSdV(t)}{(\kappa+B) I_y(t)+I_u(t)+wR(t)}.
\end{align*}
\]

When \( R_0 < 1 \), then disease die out and hence \( B = 0 \). Therefore

\[
\begin{align*}
\frac{dV}{I_y(t)+I_u(t)+wR(t)} &= \frac{1}{\kappa+B} \left[ \frac{\beta BS}{\kappa+B} \left( \mu + r_1 + d \right) I_y \right] \\
&+ w \left( r_1 I_y - \mu R \right) \\
&- \frac{1}{2 \left( I_y(t)+I_u(t)+wR(t) \right)^2} \left[ \frac{\sigma^2 p^2 B^2 S^2}{\kappa+B} + \frac{\sigma^2 q^2 B^2 S^2}{\kappa+B} \right] \\
&\quad \times \left( I_y(t)+I_u(t)+wR(t) \right) \\
&+ \frac{\sigma p BSdV(t)}{(\kappa+B) I_y(t)+I_u(t)+wR(t)} + \frac{\sigma q BSdV(t)}{(\kappa+B) I_y(t)+I_u(t)+wR(t)} \\
&+ \frac{\sigma q BSdV(t)}{(\kappa+B) I_y(t)+I_u(t)+wR(t)}.
\end{align*}
\]

Let \( \theta = \min \left( \mu + r_1 + d - wR_1, \mu + r_2 - wR_2, w \mu \right) \). It follows that

\[
\begin{align*}
\frac{dV}{I_y(t)+I_u(t)+wR(t)} &\leq -\theta \frac{dV}{I_y(t)+I_u(t)+wR(t)} \\
&+ \frac{\sigma p BSdV(t)}{(\kappa+B) I_y(t)+I_u(t)+wR(t)} + \frac{\sigma q BSdV(t)}{(\kappa+B) I_y(t)+I_u(t)+wR(t)}.
\end{align*}
\]

Introducing integral both sides from 0 to \( t \) to Equation (44) we get
\[
\ln(I_s(t) + I_a(t) + wR(t)) \\
\leq \ln(I_s(0) + I_a(0) + wR(0)) - \theta t + \int_0^t \frac{\sigma_2 I_s(s) d\mathcal{W}_2(s)}{I_s(s) + I_a(s) + wR(s)},
\]

(45)

Then from the strong law of large number for local martingale we have
\[
\lim_{t \to \infty} \frac{1}{t} \int_0^t \frac{\sigma_2 I_s(s) d\mathcal{W}_2(s)}{I_s(s) + I_a(s) + wR(s)} = 0 \quad \text{a.s.}
\]

(46)

Hence, from Equation (45) and Equation (46) we have that
\[
\limsup_{t \to \infty} \frac{1}{t} \ln(I_s(t) + I_a(t) + wR(t)) \leq -\theta < 0.
\]

This completes the proof. □

**Theorem 5.** If \( \frac{1}{2} \sigma^2 > \frac{\beta^2}{\mu} \), then the disease free equilibrium \( E' \) is almost surely stable in \( \Delta \).

**Proof.** Define a Lyapunov function as follows
\[
V = \ln\left( \frac{\Lambda}{\mu} - S \right) + I_a + R + B.
\]

Applying the Itô formula to function \( V \) above we get
\[
dV = \frac{1}{\left( \frac{\Lambda}{\mu} - S \right) + I_a + R + B} \left( -\Lambda + \frac{\beta BS}{\kappa + B} + \mu S + \frac{q\beta BS}{\kappa + B} - (\mu + r_2)I_a \\
+ r_1 I_s + r_2 I_a - \mu R \right) + \frac{1}{\frac{\Lambda}{\mu} - S + I_a + R + B} \left( \alpha_1 I_s + \alpha_2 I_a - (\delta + \phi) \right) dt
\]
\[
- \frac{1}{2} \left( \frac{\Lambda}{\mu} - S + I_a + R + B \right)^2 \left( \frac{\sigma_1^2 B^2 S^2}{(\kappa + B)^2} + \frac{\sigma_2^2 q^2 B^2 S^2}{(\kappa + B)^2} \right) dt
\]
\[
+ \frac{\sigma, B S d\mathcal{W}_1(t)}{(\kappa + B) \left( \frac{\Lambda}{\mu} - S + I_a + R + B \right)} + \frac{\sigma, q B S d\mathcal{W}_2(t)}{(\kappa + B) \left( \frac{\Lambda}{\mu} - S + I_a + R + B \right)}.
\]
(47)

From Equation (47) let \( q = 1 \) and \( p = 0 \), then
\[
dV = \frac{1}{\left( \frac{\Lambda}{\mu} - S \right) + I_a + R + B} \left( -\Lambda + \frac{2\beta BS}{\kappa + B} - \mu (S - I_a - R) + r_1 I_s + \alpha_1 I_s \\
+ \alpha_2 I_a - (\delta + \phi) B \right) dt - \frac{1}{\left( \frac{\Lambda}{\mu} - S + I_a + R + B \right)^2} \frac{2\sigma_1^2 B^2 S^2}{(\kappa + B)^2} dt
\]
\[
+ \frac{2\sigma, B S d\mathcal{W}_1(t)}{(\kappa + B) \left( \frac{\Lambda}{\mu} - S + I_a + R + B \right)}
\]
(48)
\[
dV = \frac{1}{\left(\frac{\Lambda}{\mu} - S\right) + I_a + R + B} \left\{ \frac{2\beta BS}{\kappa + B} - \Lambda - \mu(S - I_a - R) + r_t I_s + \alpha_t I_s \right. \\
+ (S - I_a - R)B \right\} dt - \frac{2\sigma_i^2 B^2 S^2}{(\kappa + B)^2 \left[ \left(\frac{\Lambda}{\mu} - S\right) + I_a + R + B \right]^2} dt \\
+ \frac{2\sigma_i B S d\mathcal{W}_i(t)}{(\kappa + B) \left[ \left(\frac{\Lambda}{\mu} - S\right) + I_a + R + B \right]},
\]

let
\[
Y = \frac{BS}{(\kappa + B) \left[ \left(\frac{\Lambda}{\mu} - S\right) + I_a + R + B \right]}. 
\]

Then, \(dV\) becomes
\[
dV = \left\{ -2\sigma_i^2 Y^2 + 2\beta Y \right\} dt - \frac{2\sigma_i^2 B^2 S^2}{(\kappa + B)^2 \left[ \left(\frac{\Lambda}{\mu} - S\right) + I_a + R + B \right]^2} dt \\
+ 2\sigma_i Y d\mathcal{W}_i(t),
\]

Then, \(dV\) deduce to
\[
dV \leq \left( -2\sigma_i^2 Y^2 + 2\beta Y - \mu \right) dt + 2\sigma_i Y d\mathcal{W}_i(t),
\]

since
\[
-2\sigma_i^2 Y^2 + 2\beta Y - \mu = -2\sigma_i^2 \left( Y - \frac{\beta}{\sigma_i^2} \right)^2 + \frac{2\beta^2 - \mu \sigma_i^2}{\sigma_i^2},
\]

we have
\[
dV \leq \frac{2\beta^2 - \mu \sigma_i^2}{\sigma_i^2} dt + 2\sigma_i Y d\mathcal{W}_i(t).
\]

Applying integration from 0 to \(t\) both sides to Equation (52), we get
\[
\ln \left( \left[ \frac{\Lambda}{\mu} - S(t) \right] + I_a(t) + R(t) + B(t) \right) \\
\leq \ln \left( \left[ \frac{\Lambda}{\mu} - S(0) \right] + I_a(0) + R(0) + B(0) \right) \\
+ \left( \frac{2\beta^2 - \mu \sigma_i^2}{\sigma_i^2} \right) t + \int_0^t 2\sigma_i Y(s) d\mathcal{W}_i(s).
\]

Then, for all time \(t \in [0, T]\), the quadratic variation of the Itô integral process \(I(Y_t)\) is deterministic integral over \([0, t]\) of \(Y_t^2\) i.e.,
\[
\left[ \int_0^t Y(s) d\mathcal{W}_i(s) \right]^2 = \int_0^t Y(s)^2 ds \leq Ct,
\]
where $C$ is a constant. Then by strong law of large number for local martingales, we have

$$\lim_{t \to \infty} \frac{1}{t} \int_0^t Y(s) \, dW_s(t) = 0 \quad \text{a.s.} \quad (55)$$

From Equation (54) and (55), we conclude that

$$\limsup_{t \to \infty} \left[ \frac{\Lambda}{\mu} - S(t) + I_s(t) + R(t) + B(t) \right] \leq \frac{2\beta^2 - \mu \sigma_1^2}{\sigma_1^2} < 0.$$

This completes the proof 5. □

**Theorem 6.** If $R_0 < 1$, then $S(t), I_s(t), I_r(t), R(t), B(t)$ converge almost surely to

$$\left( bN_c, 0, 0, 0 \right) \quad \text{in } \Lambda.$$

**Proof:** We are required to show that

$$\lim_{t \to \infty} \left( bN_c - S(t) \right) = 0 \quad \text{a.s.}$$

Consider the first equation of model system (3), let $\Lambda = bN_c$. Using Itô formula we have

$$d \left( \frac{\Lambda}{\mu} - S \right) = \left( -\mu \left( \frac{\Lambda}{\mu} - S \right) + \frac{\beta BS}{\kappa + B} \right) \, dt + \frac{\sigma_1 BSdW_1(t)}{\kappa + B}, \quad (56)$$

Applying integration both sides from $0$ to $t$ to Equation (56), we get

$$\frac{\Lambda}{\mu} - S(t) = \frac{\Lambda}{\mu} - S(0) + \int_0^t \frac{\beta BS(s)}{\kappa + B} \, ds - \int_0^t \mu \left( \frac{\Lambda}{\mu} - S(s) \right) \, ds + \int_0^t \frac{\sigma_1 BSdW_1(s)}{\kappa + B}.$$  

From the fact that $B \leq 1$ and from Theorem 4, we have in $\Lambda$ that

$$\lim_{t \to \infty} \int_0^t \frac{\beta BS(s)}{\kappa + B} \, ds \leq \lim_{t \to \infty} \int_0^t \beta S(s) \, ds \leq \beta D e^{-\alpha t} < \infty.$$

Hence

$$\lim_{t \to \infty} \left( \frac{\Lambda}{\mu} - S(t) \right) < \infty \quad \text{a.s.} \quad (58)$$

Also

$$\lim_{t \to \infty} \int_0^t \mu \left( \frac{\Lambda}{\mu} - S(s) \right) \, ds < \infty \quad \text{a.s.} \quad (59)$$

Combining Equation (57) and (59), we get

$$\lim_{t \to \infty} \int_0^t \left( \frac{\Lambda}{\mu} - S(s) \right) \, ds = \int_0^\infty \left( \frac{\Lambda}{\mu} - S(s) \right) \, ds < \infty \quad \text{a.s.} \quad (60)$$

If $S(t)$ does not converge almost surely to $\frac{\Lambda}{\mu}$, there is $\Omega \in \Omega$ such that the $\mathbb{P}(\Omega) > 0$, then for all $\omega \in \Omega$, it follows that...
Then, there exists, $T > 0$ such that
\[
\left(\frac{\Lambda}{\mu} - S(t, \omega)\right) > \frac{1}{2} \rho(\omega), \quad \forall t \geq T.
\]

We have
\[
\int_0^T \left(\frac{\Lambda}{\mu} - S(s, \omega)\right) ds = \int_0^T \left(\frac{\Lambda}{\mu} - S(s, w)\right) ds + \int_T^\infty \left(\frac{\Lambda}{\mu} - S(s, w)\right) ds \\
\geq \int_T^\infty \left(\frac{\Lambda}{\mu} - S(s, w)\right) ds = \infty.
\]

Then, as $\Omega_1 \subseteq \Omega_2$, where
\[
\Omega_2 = \left\{ \omega, \int_0^T \left(\frac{\Lambda}{\mu} - S(s, \omega)\right) ds = \infty \right\}.
\]

It implies that $\mathbb{P}(\Omega) > 0$. But from Equation (57), we see that $\mathbb{P}(\Omega) = 0$. This leads to contradiction.

Hence,
\[
\lim_{t \to \infty} \frac{\Lambda}{\mu} - S(t) = 0 \quad \text{a.s.}
\]

This completes the proof of Theorem 6. $\square$

5. Numerical Results

In this section, we numerically solve the ordinary differential Equation (ODEs) model (1) and stochastic differential Equation (SDEs) model (3) and (8) by fourth order Runge-Kutta and Euler-Maruyama scheme respectively. The behaviour of individuals sample path of the stochastic differential equation models are compared to the deterministic solution. Initially, one infective is introduced into a population. The time step is $\Delta t = 0.01$ and the time axis is the number of time steps, e.g., Time = 100 means 100 time steps and thus, an actual total time of $100 \Delta t = 1$. The Euler-Maruyama scheme is one of the numerical methods for computing the sample paths of SDEs (3) and (8) [21]. This method is a finite difference approximation
\[
x(t + \Delta t) = x(t) + f(x(t), t) \Delta t + G(x(t), t) \rho \sqrt{\Delta t},
\]
\begin{equation}
\tag{62}
\end{equation}

From Equation (62), the vector $\rho = (\rho_1, \cdots, \rho_j)$ is $j$ independent standard normal random numbers $\rho_j \in N(0, 1)$. Also, $t = 0, \Delta t, 2\Delta t, \cdots$, and $\Delta t$ is chosen sufficiently very small to ensure good convergence. The sample path of the $SIIR - B$ stochastic differential equations is shown in Figure 6. It is observed that the sample path is continuous but not differentiable (a Wiener process property).

Maximum likelihood estimation method is used to estimate the unknown parameters $\theta$ of a SDE (8) by maximizing the likelihood [16].
Let \( p(t_k, x_k | t_{k-1}, x_{k-1}; \theta) \) be the transition probability density of \((t_{k-1}, x_{k-1})\) given vector \( \theta \). Suppose that the density of the initial state is \( p_0(x_0 | \theta) \), in maximum likelihood estimation of \( \theta \) [16], the joint density

\[
D(\theta) = p_0(x_0 | \theta) \prod_{k=1}^{N} p(t_k, x_k | t_{k-1}, x_{k-1}; \theta),
\]

is maximized over \( \theta \in \mathbb{R}^m \). The value of \( \theta \) that maximizes \( D(\theta) \) will be denoted by \( \theta_\ast \in \mathbb{R}^m \). For simplicity, it is more convenient to minimize the function

\[
L(\theta) = -\ln\left( p_0(x_0 | \theta) \right) - \sum_{k=1}^{N} \ln\left( p(t_k, x_k | t_{k-1}, x_{k-1}; \theta) \right),
\]

where, \( p(t_k, x_k | t_{k-1}, x_{k-1}; \theta) \) is computed recursively by extended Kalman filter and its approximation is

\[
\eta(\theta) = \sum_{j=1}^{N} \frac{1}{2} \ln(2\pi S_j) + \frac{1}{2} \sum_{j=1}^{N} \left( y_j - h(m_j, t) \right)^\top S_j^{-1} \left( y_j - h(m_j, t) \right) - \ln p(\theta),
\]

where

\[
\begin{align*}
S_j &= H_j(m_j) p_j H_j^\top(m_j) + Z_j, \\
K_j &= p_j H_j^\top(m_j, t) S_j^{-1}, \\
m_j &= m_j^+ + K_j \left( y_j - h(m_j^-) \right), \\
p_j &= p_j^+ - K_j S_j K_j^\top,
\end{align*}
\]

\( H_j(x, t) \) is the Jacobian matrix of \( h(x, t) \), \( y_j = h(x(t_j)) + z_j \), \( y_j \) is the measurement at time \( t_j \), \( x(t_j) \) is the state at time \( t_j \), \( \theta \) is the vector of parameter to estimated, \( Z_j \) is the covariance matrix of the measurement error at \( t_j \). However, at \( t_0 \) the state is assumed to have the prior distribution. For more details on EKF (see [22]).

The estimated parameters by MLE are shown in Table 2. It is observed that the estimates are close to the true parameter values. Figures 2-5 show the extended Kalman filter estimates together with the true solution from ODE, measurements and states. Here black line, blue line and green line represents ODE solution, measurements and states realizations respectively. It is observed that the extended Kalman filter fits the states, which means states \((S(t), I_s(t), I_a(t), R(t))\) can easily be estimated. The stochastic model (3) can be re-written in the following discretization equations:

\[
\begin{align*}
S_{k+1} &= S_k + \left[ bN + \frac{\beta B S_k}{K + B_k} - \mu S_k \right] \Delta t - \sigma_1 B S_k \sqrt{\Delta t} Z_k, \\
I_{ak+1} &= I_{ak} + \left[ \frac{p B S_k}{K + B_k} - (\mu + r_1 + d) I_{ak} \right] \Delta t - \sigma_2 B S_k \sqrt{\Delta t} Z_k, \\
I_{sk+1} &= I_{sk} + \left[ \frac{q B S_k}{K + B_k} - (\mu + r_2) I_{sk} \right] \Delta t - \sigma_3 B S_k \sqrt{\Delta t} Z_k,
\end{align*}
\]
Figure 2. The sample path of $S(t)$ for SDE (8) and deterministic solution for $S(t)$ graphed with extended Kalman filter estimates.

Figure 3. The sample path of $R(t)$ for SDE (8) and deterministic solution for $R(t)$ graphed with extended Kalman filter estimates.

Figure 4. The sample path of $I_a(t)$ for SDE (8) and deterministic solution for $I_a(t)$ graphed with extended Kalman filter estimates.
Figure 5. The sample path of $I_s(t)$ for SDE (8) and deterministic solution for $I_s(t)$ graphed with extended Kalman filter estimates.

$$R_{k+1} = R_k + (r_1I_{sk} + r_2I_{ak} - \mu R_k) \Delta t,$$

$$B_{k+1} = B_k + (\alpha_1I_{sk} + \alpha_2I_{ak} - (\delta + \phi)B_k) \Delta t,$$

where $Z_k (k=1,2,\cdots,n)$ is the Gaussian random variables $N(0,1)$. The Euler-Maruyama scheme is used to simulate the sample paths of stochastic differential Equation (3) and the result is graphed in Figure 6. From Figure 6, we observe that the susceptible proportion eventually converges to zero; the entire population becomes infected, and later they recover from the disease. Also, the sample path of $SI_sI_RB$ stochastic differential equations is continuous but not differentiable (a property of Wiener process).

The sample path of $SI_sI_RB$ stochastic differential equations model together with the solutions of ordinary differential equations is graphed in Figure 7. From Figure 7, we find that the sample path of $SI_sI_RB$ stochastic differential equations model fluctuates within the solution of the $SI_sI_RB$ ordinary differential equation model.

6. Discussion

We have proposed a new modeling framework for the dynamics of cholera using both deterministic and stochastic models. Our focus is on the interaction of environmental vibrios to human (which causes the transformation from the environmental vibrios to human) and the infected individuals shedding bacteria into the environment. For deterministic model, we derived the basic reproduction number $R_0$. The basic reproduction number is a critical parameter for disease dynamics. In the deterministic model, the value of the basic reproduction number $R_0$ determines the persistence or extinction of the disease. If $R_0 < 1$, the disease is eliminated, whereas if $R_0 > 1$, the disease persists in the population. From the deterministic model we have formulated two stochastic differential equations using parametric perturbation and transition probabilities methods.
Figure 6. The sample path of \( S(t), I_s(t), I_a(t), R(t) \) for SDE model (3) when \( \Delta t = 0.01 \), \( \sigma_1 = 0.2 \) and \( \sigma_2 = 0.1 \).

Figure 7. The sample path of \( S(t), I_s(t), I_a(t), R(t) \) for SDE model (3) are graphed with the deterministic solutions (dashed curve) when \( \Delta t = 0.01 \), \( \sigma_1 = 0.2 \) and \( \sigma_2 = 0.1 \).
We have proved the existence and uniqueness of positive solution, we showed that the solution of stochastic model are stochastically ultimately bounded, we derived that when $R_0 < 1$, then the infected compartments and bacteria goes to extinction. We carried out numerical simulation using Euler-Maruyama scheme to simulate the sample paths of stochastic differential Equation (3). Our results show that, the sample paths are continuous but not differentiable (a property of Wiener process) Also, we carefully compared the numerical simulation results for deterministic and stochastic models. We find that, the sample path of $SI_1I_2R - B$ stochastic differential equations model fluctuates within the solution of the $SI_1I_2R - B$ ordinary differential equation model as seen in Figure 7. However, the model parameters of SDEs are estimated by maximum likelihood estimation method. It is shown that the estimates are close to the true parameter values as seen in Table 2. Also, we used extended Kalman filter to estimate the states (compartments) of stochastic model (8) by recursively computing the transition probability density. It is observed that the state estimates fit the measurements as seen in Figures 2-5. Hence, we find that both models that are deterministic and stochastic models are very useful in understanding the dynamics of cholera epidemic. Nevertheless, Stochastic differential equation models are more important than deterministic models since they incorporate random effects such as environmental stochasticity and this enables us to model different quantities such as probability of extinction, probability of distributions and variances which cannot be captured in deterministic models.

7. Conclusions

In this paper, two stochastic differential equations models are formulated from the deterministic model using two different approaches: parametric perturbation and Transition probabilities. For deterministic model, the basic reproduction number $R_0$ determines whether the disease is eliminated or persists in the given population. For stochastic model, the perturbed stochastic differential equation is first analyzed by proving the existence and positivity of the solutions. Secondly, we looked at the stability aspect of the model; we proved that the number of symptomatic infected, asymptomatic infected and bacteria tends to asymptotically to zero exponentially almost surely. Also, we showed that the equilibrium solution of the SDEs is $p$th moment exponentially stable and it is usually said to be exponentially stable in mean square. Numerical simulations are carried to simulate the sample paths of stochastic models by Euler-Maruyama scheme and the

| Parameter | $b$ | $\beta$ | $\kappa$ | $\alpha_1$ | $\alpha_2$ | $d$ | $\delta$ | $\phi$ | $r_1$ | $r_2$ | $p$ | $q$ | $\mu$ |
|-----------|-----|---------|---------|-----------|-----------|----|-------|-------|------|------|----|----|------|

| Source | [23] | [26] | [26] | [23] | [23] | [25] | [7] | [23] | [23] | [23] | [7] | [7] | [23] [24] |
| Estimates | 0.00007169 | 0.3479 | 855,526.77 | 1.48 | 0.088 | 0.000556 | 0.046 | 0.022 | 0.134 | 0.51 | 0.66 | 0.268 | 0.0000442 |

Table 2. Estimated model parameters for cholera epidemic by MLE.
solutions of deterministic model by fourth order Runge-Kutta method. It is observed that the sample paths are continuous but not differentiable (a property of Wiener process) and the sample paths of stochastic differential equations models fluctuate within the solutions of deterministic model. However, the model parameters of SDEs are estimated by maximum likelihood estimation method. It is shown that the estimates are close to the true parameter values. Also, extended Kalman filter is used to estimate the states of stochastic model by recursively computing the transition probability density. It is observed that the state estimates fit the measurements. So, we can say that cholera transmission dynamics can be modeled using stochastic differential equations. It is clear that real world problems such as disease are not deterministic in nature so including random effects to the model gives us a more realistic way of modeling cholera epidemics and other epidemic diseases. For example, using stochastic differential equation model we managed to examine the limiting asymptotic distribution of the number of symptomatic infected, asymptomatic infected and bacteria.
