(Dated: May 2, 2014)

Theoretical framework— LQC is formulated in the canonical language. Because of general covariance the canonical Hamiltonian is a combination of constraints \( C_I \). Consistency requires that the constraints are preserved under the evolution they generate. This is assured in the classical theory by the closure of the Poisson algebra of the constraints

\[
\{ C_I, C_J \} = f^K_{IJ}(A^j_k, E^a_i) C_K, \tag{1}
\]

where \( C_I, I = 1, 2, 3 \), are the Gauss, diffeomorphism and Hamiltonian constraints and \( f^K_{IJ}(A^j_k, E^a_i) \) are structure functions which, in general, depend on the phase space (Ashtekar) variables \( (A^j_k, E^a_i) \). In LQC, quantum corrections can be studied as effective modifications of the Hamiltonian constraint. In doing so, anomalies generically appear: the modified constraints \( C^Q_I \) do not form a closed algebra anymore:

\[
\{ C^Q_I, C^Q_J \} = f^K_{IJ}(A^j_k, E^a_i) C^Q_K + A_{IJ}. \tag{2}
\]

The anomalous term \( A_{IJ} \) can be removed by carefully adjusting the form of the quantum correction to the Hamiltonian constraint. This is achieved by adding suitable “counterterms” that vanish in the classical limit. The resulting deformed algebra can be phenomenologically very rich.
In the case of a flat FLRW background, the Ashtekar variables can be decomposed as follows

\[ A^i_a = \gamma \bar{k} \delta_a^i + \delta A^i_a \quad \text{and} \quad E_i^a = \bar{\rho} \delta_a^i + \delta E_i^a, \tag{3} \]

where \( \bar{k} \) and \( \bar{\rho} \) parametrize the background phase space, and \( \gamma \) is the Barbero-Immirzi parameter. The variation of the connection receives contributions from the fluctuations of both the intrinsic and extrinsic curvature: \( \delta A^i_a = \delta \Gamma^i_a + \gamma \delta K^i_a \).

LQC generates two main classes of effective corrections to the constraints, called the inverse-volume corrections and the holonomy corrections \[2\]. The closure of the algebra of cosmological perturbations has been extensively studied for inverse-volume corrections. It was explicitly shown that closure can indeed be achieved. This was demonstrated for scalar \[4,5\], vector \[6\] and tensor modes \[7\]. Using the anomaly-free scalar perturbations, predictions for the power spectrum were also obtained \[8\]. This allowed to put constraints on some parameters of the model using observations of the cosmic microwave background radiation (CMB) \[9\].

Here, we focus on the holonomy corrections – appearing because of the use of the holonomy of the Ashtekar connection. It is worth emphasizing that for tensor modes, the algebra is automatically anomaly-free. For this reason, several works were devoted to the phenomenology of holonomy-corrected tensor perturbations (see \textit{e.g.} \[10\]). The anomaly-free algebra for vector modes was studied in \[11\] and recently fully derived, including matter, in \[12\]. The scalar algebra was obtained in \[13\].

\textbf{Perturbations–} Taking into account the form of the perturbed variables \[3\], we introduce a general expression for the variation of the spin connection as

\[ \delta \Gamma^i_a = \frac{1}{2 \bar{\rho}} X^{ijb}_{ca} \partial_b \delta E^c_j + \frac{1}{2 \bar{\rho}^2} Y_{abc}^{ijkl} \delta E^c_j \partial_b \delta E^a_i, \tag{4} \]

where

\[ X^{ijb}_{ca} = \varepsilon^i_c \delta^a_b - \varepsilon^i_b \delta^a_c + \varepsilon^{ijb} \delta^a_c + \varepsilon^{aib} \delta^c_j. \tag{5} \]

\( Y_{abc}^{ijkl} \) has an expression similar to \( X^{ijb}_{ca} \), but more complicated: it is not needed here explicitly, because it appears only as a boundary term in the second order term of the Hamiltonian constraint \[15\] in a way that does not affect the equations of motion. The information about what kind of perturbations we consider (scalar, vector or tensor perturbations) is coded in the term \( \frac{1}{2 \bar{\rho}} X^{ijb}_{ca} \partial_b \delta E^c_j \).

The variation of the densitized triad can be decomposed as follows:

\[ \delta E_i^a = \bar{\rho} \left[ -2 \psi \delta^i_a + (\delta^i_a \partial_c \partial_a - \partial^a \partial_i) E_i^a - c_1 \partial^a F_i^a - c_2 \partial_i F^a - \frac{1}{2} h_a^i \right], \tag{6} \]

where the first two terms \( \psi \) and \( E \) correspond to scalar modes, the terms with \( F_i \) and \( F^a \) to vector modes and the term with \( h_a^i \) to the tensor mode. Vector modes are transverse, and tensor modes are transverse and traceless. These conditions constrain \( \delta E_i^a \) and \( \delta K_a^i \), as well as the lapse \( \delta N \) and the shift vector \( \delta N^a \). In particular, vanishing trace implies

\[ \delta_a^i \delta_i^a = \delta^a_a \delta K_a^i = 0. \tag{7} \]

Tensor and vector perturbations satisfy this condition, so that in these cases the terms containing these expressions disappear from the constraints. The form of the metric in the case of vector and tensor modes implies that the variation of the lapse is zero: \( \delta N = 0 \). Therefore, some first-order constraints do not influence the perturbed dynamics.

For vector modes, the variation of the shift corresponds to one of the two degrees of freedom indicated with \( S_a \) and \( F_i \): \( \delta N^a = S^a \). For tensor modes instead, the transverseness, \textit{i.e.} null divergence, implies

\[ \partial^a \delta E^a_i = 0. \tag{8} \]

As above, the form of the metric for tensor modes implies \( \delta N^a = 0 \) for the shift, so that some further first-order terms do not contribute to the dynamics.

Scalar perturbations are the more general: no term disappears and all the constraints contribute to define the perturbed dynamics. We have

\[ \delta N = \tilde{N} \phi \quad \text{and} \quad \delta N^a = \partial^a B, \tag{9} \]

where \( \tilde{N} \) is the unperturbed part of the lapse \( N = \tilde{N} + \delta N \) and \( \phi \) and \( B \) are scalar fields.

If we turn-on the quantum corrections by modifying the Hamiltonian constraint, anomalies appear and we have to add counterterms in order to make the Poisson algebra closed. In previous works, these counterterms were found considering separately the case of each kind of modes. The tensor and vector cases were simpler because of the vanishing of several terms in the constraints, as observed. The scalar case, on the other hand, is from this perspective the most general one, since all the constraint terms are present. It is indeed easy to see that the counterterms that adjust the Hamiltonian for the scalar case \[15\] work also for the vector and tensor cases, thus providing a general solution to the closure of the algebra. Therefore starting from the scalar case it is possible to define a unique closed algebra of modified constraints, with the most general counterterms, giving back correct counterterms for scalar and tensor perturbations when imposing transverseness and vanishing trace.

\textbf{Constraints–} We consider the algebra of the diffeomorphism and Hamiltonian constraints (see \[2\] for the expression of the constraints in terms of the variables \[3\]). In each constraint, gravity and matter – here modeled by a single scalar field with canonical variables \( (\varphi, \pi) \) – contribute.
Diffeomorphism constraint— The diffeomorphism constraint can be decomposed as
\[
D[N^a] = \int d^3 x \left( \bar{N}^{a} \left( (D^{(0)} + D^{(2)}) + \delta N^{a} D^{(1)} \right) \right). \tag{10}
\]
Since we are considering an FLRW background metric, the shift \( N^a = \bar{N}^a + \delta N^a \) has zero \( N^a \). This implies that the diffeomorphism constraint can be considered at the first order.

Using the symmetry properties of \([5]\) we can write the constraint for the gravitational part as
\[
\kappa D_g = \bar{p} \partial_a \delta K^d_a - \bar{p} \partial_a \delta K^d_a - \bar{k} \partial_a \delta E^d_a, \tag{11}
\]
and for the matter part as
\[
D_m = \bar{\pi} \partial_a \delta \varphi. \tag{12}
\]
Recall that for tensor modes \( \delta N^a = 0 \), therefore \( D_g \) and \( D_m \) play a role only for scalar and vector perturbations.

Hamiltonian constraint— We consider the gravitational part of the Hamiltonian constraint up to the second order:
\[
H[N] = \int d^3 x \left[ \bar{N} \left( (\mathcal{H}^{(0)} + \mathcal{H}^{(2)}) + \delta N \mathcal{H}^{(1)} \right) \right]. \tag{13}
\]
Using again the symmetry properties of \([5]\), the expansion of the constraint given in \([2]\) gives
\[
2\kappa \mathcal{H}^{(0)} = -6\sqrt{\bar{p}} \bar{k}^2, \tag{14}
\]
at zeroth order and
\[
2\kappa \mathcal{H}^{(1)} = -4\sqrt{\bar{p}} \delta K^d_a + \frac{\bar{k}}{\sqrt{\bar{p}}} \partial^i \partial_a \delta E^i_a, \tag{15}
\]
at first order, for all kinds of perturbations. On the other hand, the second order turns out to be
\[
2\kappa \mathcal{H}^{(2)} = -2\frac{\bar{k}}{\sqrt{\bar{p}}} \delta K^d_a \delta E^a_d + \frac{\bar{k}^2}{\sqrt{\bar{p}}} \delta K^d_a \delta E^a_d
+ \sqrt{\bar{p}} \left( \delta^i_b \delta K^d_{a} \delta^j_d \delta K^i_b - \delta^i_b \delta K^d_{a} \delta^j_d \delta K^i_b \right)
+ \frac{1}{4 \bar{p}^2} \left( \delta^i_b \delta E^a_{d} \delta^j_d \delta E^b_j - 2 \delta^i_b \delta E^a_{d} \delta^j_d \delta E^b_j \right)
+ \frac{1}{\bar{p}^2} X_{d}^{j d} \epsilon_{i k} \partial_a \left( \delta E^d_i \partial_a \delta E^j_d \right)
+ \frac{1}{\bar{p}^2} Z_{a b}^{c d} \left( \partial_a \delta E^c_d \right) \left( \partial_b \delta E^d_b \right) \tag{16}
\]
and is different depending on the mode considered. The difference is only in the term \( Z_{a b}^{c d} \). Its explicit form reads
\[
Z_{a b}^{c d} = \frac{1}{4} \epsilon_{k}^{i j} \epsilon_{m n} X_{m c}^{j d} X_{a f}^{i e} - \epsilon_{k}^{i j} X_{b c}^{j d} \delta_{a}^{e}
- \epsilon_{k}^{i j} X_{b a}^{j d} + \frac{1}{2} \delta_{a}^{e} \epsilon_{k}^{i j} X_{b c}^{j d}. \tag{17}
\]
Imposing the conditions that define each mode and using \([5]\), we obtain that the term \( Z_{a b}^{c d} \left( \partial_a \delta E^c_d \right) \left( \partial_b \delta E^d_b \right) \) in \([16]\) is respectively
\[
\delta_{a b} \delta_{c d} \left( \partial_a \delta E^c_d \right) \left( \partial_b \delta E^d_b \right) \quad \text{for tensor modes}, \tag{18}
\]
\[
0 \quad \text{for vector modes}, \tag{19}
\]
\[
- \frac{1}{2} \delta_{a}^{e} \delta_{b}^{i} \delta_{d}^{j} \left( \partial_a \delta E^c_d \right) \left( \partial_b \delta E^d_b \right) \quad \text{for scalar modes}. \tag{20}
\]
This term is the only one that takes different forms when restricted to perturbations of the scalar, vector or tensor types. It follows that only the counterterms originating from this term will differ from one another for different types of perturbations.

Quantum corrections— In the classical case, the algebra is closed:
\[
\{ D_m^{(n+g)}[N^a], D_m^{(n+g)}[N^a] \} = 0, \tag{21}
\]
\[
\{ H_m^{(n+g)}[N^a], D_m^{(n+g)}[N^a] \} = -H_m^{(n+g)}[\delta N^a \partial_a \delta N], \tag{22}
\]
\[
\{ H_m^{(n+g)}[N^a], H_m^{(n+g)}[N^a] \} = D_m^{(n+g)} \left[ \frac{2}{3} \partial^a (\delta N_2 - \delta N_1) \right]. \tag{23}
\]
This term is not under corrections from quantum effects \([12]\). We add quantum corrections at an effective level by replacing in the Hamiltonian constraint
\[
\bar{k} \to \frac{\sin(\bar{\mu} \gamma \bar{k})}{\bar{\mu} \gamma}, \tag{24}
\]
as a result of the quantization of the holonomies \([13]\). The parameter \( \bar{\mu} \), proportional to the ratio between the Planck length and the scale factor, carries the information on the scale at which quantum corrections become relevant. This yields the quantum-corrected Friedmann equations
\[
H^2 = \frac{\kappa}{3} \rho \left( 1 - \frac{\rho}{\rho_c} \right) = \mathcal{H}^2 \tag{25}
\]
where \( H \) and \( \mathcal{H} \) are the Hubble rate respectively in cosmic time and in conformal time, \( \rho \) is the energy density and \( \rho_c \approx 0.4 \rho_{\gamma} \) is the energy density at which a repulsive quantum-gravity force appears, removing the classical initial singularity \([2]\). The appearance of anomalies is contrasted by inserting counterterms in \( \mathcal{H}^{(1)} \) and \( \mathcal{H}^{(2)} \). For the explicit form of the resulting constraints, we refer the reader to the literature (see \([15]\)). The same modified constraints have been found in \([10]\), where the counters of \([15]\) appears naturally after a Taylor expansion of the holonomies of the perturbed Ashtekar connection.

We are here interested in the structure of the resulting closed algebra.

Results— Remarkably, the resulting quantum-corrected algebra valid for all different kind of perturbations is obtained with a single structure modification \([21][23]\). This appears in the last equations \([23]\), which becomes
\[
\{ H_{m}^{(n+g)}[N^a], H_{m}^{(n+g)}[N^a] \} = \Omega D^{(n+g)} \left[ \frac{\bar{N}}{\bar{p}} \partial^a (\delta N_2 - \delta N_1) \right]. \tag{26}
\]
where
\[ \Omega = \cos(2\bar{\mu}^\gamma \bar{h}) = 1 - 2 \frac{\rho}{\rho_c}. \]  

(27)

The single \( \Omega \) factor represents the quantum correction. It goes to 1 in the classical limit. This simple correction appears also in the definition of the evolution of the perturbations using gauge-invariant observables.

**Mukhanov-Sasaki equations of motion**—Finally, we can derive the correction to the Mukhanov-Sasaki [17] equation of motion for gauge-invariant perturbations of scalar and tensor type \( v_{S(T)} \). In conformal time, this is given by \[15, 18\]

\[ v''_{S(T)} - \Omega \nabla^2 v_{S(T)} - \frac{z''_{S(T)}}{z_{S(T)}} v_{S(T)} = 0, \]  

(28)

which reduces to the classical equation when \( \Omega \to 1 \). This equation holds for both scalar and tensor perturbations. Since we have considered the simple case of a scalar field, there is no vorticity and therefore there is no physical solution corresponding to vector perturbations.

For scalar perturbations, the Mukhanov variables in the quantum case are given by

\[ v_S = \sqrt{\bar{p}} \left( \delta \phi + \frac{\partial \phi}{\partial \mathcal{H}} \right) \quad \text{and} \quad z_S = \sqrt{\bar{p}} \frac{\partial \phi}{\partial \mathcal{H}}. \]

(29)

If we impose the divergence and the trace to be zero, we obtain for tensor modes

\[ v_T = \sqrt{\bar{p}} \frac{\bar{h}}{\Omega} \quad \text{and} \quad z_T = \sqrt{\bar{p}} \frac{\bar{h}}{\Omega}, \]

(30)

where \( \bar{h} \) represents the two degrees of freedom of \( h^i_a \). Inserting (30) into (28) we obtain the following form of the equations of motion for tensor perturbations:

\[ h''^i_a + h'^i_a \left( 2 \mathcal{H} - \frac{\Omega}{\Omega} \right) - \Omega \nabla^2 h^i_a = 0. \]

(31)

This equation is clearly different from what has been used in previous works.

**Conclusions**—We have presented a consistent framework for the study of perturbations in Loop Quantum Cosmology. It is possible to write down a unique quantum-corrected algebra. This has a simple form, and the same quantum correction holds for all the different kinds of perturbations.

This simple correction also appears in the Mukhanov-Sasaki equation, and consists in the insertion of the single factor (27), which becomes relevant only when the matter energy density approaches the Planck scale.

We notice that there exist a small region in the strong quantum regime where \( \Omega \) becomes negative. This yields a change of signature of the effective metric \[15, 19\] associated to the appearance of divergences in the equation of motion of cosmological perturbations. As a consequence, new observable features could appear since the value of tensor modes would be higher than in the classical case. This have to be further investigated, possibly going beyond the effective treatment.

The existence of a single deformed closed algebra for all kind of perturbations, as exhibited in this work, is a strong case for the self-consistency of effective LQC.
