Abstract

The Residual Smoothing Scheme (RSS) have been introduced in [1] as a backward Euler’s method with a simplified implicit part for the solution of parabolic problems. RSS have stability properties comparable to those of semi-implicit schemes while giving possibilities for reducing the computational cost. A similar approach was introduced independently in [10, 11] but from the Fourier point of view. We present here a unified framework for these schemes and propose practical implementations and extensions of the RSS schemes for the long time simulation of nonlinear parabolic problems when discretized by using high order finite differences compact schemes. Stability results are presented in the linear and the nonlinear case. Numerical simulations of 2D incompressible Navier-Stokes equations are given for illustrating the robustness of the method.

1 Introduction

It is a common fact in numerical analysis that the choice of a time marching scheme must balance stability, accuracy and reasonable computational cost. Typically, when considering e.g. the numerical solution of a space-discretized parabolic problems, such as

\[
\frac{du}{dt} + Au = f, \quad u(0) = u_0,
\]

(1)

where \( A \) denotes the stiffness matrix, it is well known that the implicit schemes are stable but need an additional problem to be solved at each step while the explicit schemes are very cheap
but suffer of a hard time step limitation making them bad suited for capturing the long time behavior of the solutions. An ideal scheme should combine stability and low computational cost (explicity) for a comparable accuracy.

Two independent attempts have been made successfully in that direction:

First, A. Cohen and al proposed in [1] the following stabilization to the forward Euler scheme (Residual Smoothing Scheme or RSS) for the discretized parabolic equations associated to homogeneous Dirichlet (or Neumann) Boundary conditions:

\[
\frac{u^{(k+1)} - u^{(k)}}{\Delta t} + \tau B(\frac{u^{(k+1)} - u^{(k)}}{\Delta t}) + Au^{(k)} = f,
\]  

(2)

where \( \tau \) is a positive real number to be chosen and \( B \) a preconditioner of the stiffness matrix \( A \). Originally introduced in the context of wavelet discretizations, the matrix \( B \) can be taken as the diagonal part of \( A \) and is then an unconditional preconditioner: the new scheme is no more expensive than the classical forward Euler’s while the stability is increased. However, RSS is only first order accurate in time and, in order to increase the accuracy, it was proposed in [1] to apply a Richardson extrapolation; typically a second order of accuracy was obtained as shown by numerical evidences. A rough analysis of the stabilized and extrapolated scheme was made by Ribot and Schatzman [16, 17], they derived stability and error estimates in energy norms.

Independently, Costa, Dettori, Gottlieb and Temam have introduced in [10, 11] a similar approach but starting from a Fourier-analysis point of view, in the context of multiresolution methods of nonlinear Galerkin type for spectral discretizations (Fourier, Chebyshev), see [19]. They proposed to stabilize the forward Euler scheme for the heat equation

\[ u_t - u_{xx} = f, \]

by adding a stabilization term of the form \( \beta \frac{du}{dt} \). The new scheme writes in Fourier basis as

\[
\frac{\hat{u}_m^{(k+1)} - \hat{u}_m^{(k)}}{\Delta t} + \beta_j \frac{\Delta t}{\Delta t} (\hat{u}_m^{(k+1)} - \hat{u}_m^{(k)}) = -m^2 \hat{u}_m^{(k)} + \hat{f}_m, \quad m = N_{j-1}, \ldots, N_j,
\]

(3)

where we have decomposed the frequency range \([1, N]\) into \( \bigcup_{j=1}^{d} [N_{j-1}, N_j] \). In other words

\[
\frac{\hat{u}^{(k+1)} - \hat{u}^{(k)}}{\Delta t} - B(\hat{u}^{(k+1)} - \hat{u}^{(k)}) = -D\hat{u}^{(k)} + \hat{f},
\]

with \( D = \text{diag}(1, 4, 9, \cdots N^2) \) and

\[
B = \begin{pmatrix}
B_1 & 0 & 0 \\
0 & \ddots & \ddots \\
0 & \ddots & B_d
\end{pmatrix},
\]
with $B_j = \beta_j I_{d_j}$, $I_{d_j}$ being the identity matrix of size $(N_j - N_{j-1}) \times (N_j - N_{j-1})$ (we have set $N_0 = 0$ and $N_d = N$); $B$ is then a preconditioner of $D$ in the Fourier space. In the linear case, these two approaches coincide. Of course, same framework can be derived when considering orthogonal polynomials. Costa and Chehab [7, 8] have extended this scheme to hierarchical discretizations in finite differences.

The main advantage of the RSS approach is that a simplified (yet costless) solver is used for the implicit part of the time marching scheme while displaying comparable stability properties to Backward’s Euler Scheme. One situation of particular interest, on which we focus in the present work, occurs when handling high order discretizations of the stiffness matrix $A$, e.g. with finite differences compact schemes. In that case, $A$ is full, this is due to the implicit part of the scheme. Hence, matrix-vector product are costly and must be reduced as far as possible. A lower level of space discetization (say second order) generates a sparse stiffness matrix $B$ which is a natural efficient preconditioner of $A$. Then, the RSS scheme can be implemented efficiently taking advantage of the existing (sometimes fast) solvers of the system of the form

$$(I_d + \Delta t B)u = f,$$

such as sparse factorizations and FFT.

The RSS approach can be proposed to solve fully discretized time dependent PDEs with high accurate spatial discretization, with compact scheme, while using the computational facilities of the sparse numerical solvers (Fast solvers, limited memory).

In this article, we propose a unified approach to RRS-like schemes that rely [1] and [11]. We derive stability results in the linear and the nonlinear case; we also present practical and efficient adaptations for the high accurate finite differences solutions of nonlinear parabolic equations.

The paper is organized as follows: in Section 2, we derive a general approach to RSS schemes and we give stability results in the linear and the nonlinear case, the accuracy in time of the new scheme is also discussed. After that, in section 3, we describe the compact scheme discretization and the preconditioning that will be used. Section 4 is devoted to numerical illustrations, we compare RSS approach to the classical one with emphasis on the stability, the accuracy (particularly the dynamics to steady state) and for that purpose, we solve high accurate finite difference steady state of 2D incompressible Navier-Stokes equations (Lid driven cavity) and recover the results of the literature.

2 Derivation of the stabilized schemes - properties

2.1 Formal Derivation of the stabilized schemes

Let us consider the finite dimensional differential system

$$\frac{du}{dt} + F(u) = 0, \quad t > 0,$$

$$u(0) = u_0,$$

(4)

(5)
here $F : \mathbb{R}^N \rightarrow \mathbb{R}^N$ is a regular map. The backward Euler scheme applied to the above system generates the iterations
\[ u^{(k+1)} - u^{(k)} + \Delta t F(u^{(k+1)}) = 0, \]
and a (possibly) nonlinear problem must be solved at each step. Making the approximation
\[ F(u^{(k+1)}) \approx F(u^{(k)}) + F'(u^{(k)})(u^{(k+1)} - u^{(k)}), \]
where $F'(u^{(k)})$ denotes the differential of $F$ at $u^{(k)}$, we obtain the scheme
\[ \frac{u^{(k+1)} - u^{(k)}}{\Delta t} + F'(u^{(k)})(u^{(k+1)} - u^{(k)}) + F(u^{(k)}) = 0, \]
so
\[ u^{(k+1)} = u^{(k)} - \Delta t(Id + \Delta t F'(u^{(k)}))^{-1} F(u^{(k)}). \]
Setting $\Phi(v) = v - u^{(k)} + \Delta t F(v)$, we see that $u^{(k+1)}$ is nothing else but the first iteration of the Newton-Raphson scheme applied to $\Phi(v)$ when starting from the initial guess $u^{(k)}$.  

Now, if we replace $F'(u^{(k)})$ by a preconditioner $\tau B_k$, we find
\[ \frac{u^{(k+1)} - u^{(k)}}{\Delta t} + \tau B_k (u^{(k+1)} - u^{(k)}) + F(u^{(k)}) = 0, \]  
\[ \text{Global stabilization} \]  
and $u^{(k+1)}$ is thus the first iteration of a quasi Newton Method applied to $\Phi(v)$ when starting from the initial guess $u^{(k)}$.  

The efficiency of this stabilized scheme is closely related to the cost of the computation of the preconditioner of the jacobian matrix which changes at each iteration: technique of existing updating factorizations as those presented in [6] and [2] could be adapted.  

In the present work, we will not discuss on the analysis of the nonlinear version of the scheme, say (7), but we will present on Section 4 numerical results obtained with this scheme. We will rather consider the semi linear approach: if $F(u)$ can be expressed as $F(u) = Au + f(u)$, we define teh scheme
\[ \frac{u^{(k+1)} - u^{(k)}}{\Delta t} + \tau B_k (u^{(k+1)} - u^{(k)}) + F(u^{(k)}) = 0, \]  
\[ \text{Stabilization of the linear part} \]  
where $B$ is a preconditioner of $A$.

It is important to point out that (7) is consistant with the computation of steady states and can then be applied as a pseudo-time numerical solver, as illustrated in Section 4 with impressive NSE.
Of course this stabilization approach applies to the linear case \(f(u) = 0\). Particularly, RSS is a simplified \(\theta\)-scheme in which the matrix \(A\) is replaced by a preconditioner. Indeed, the \(\theta\)-scheme write, after simplifications as

\[
u^{(k+1)} = u^{(k+1)} - \Delta t(Id + \theta \Delta tA)^{-1}(Au^{(k)} - f)
\]

and, substituting \(A\) by \(B\) in the implicit part, we recover the RSS

\[
u^{(k+1)} = u^{(k+1)} - \Delta t(Id + \theta \Delta tB)^{-1}(Au^{(k)} - f)
\]

with \(\theta = \tau\).

In practice, the use of a preconditioner \(B\) of \(A\) leads to propose \(K = Id + \tau \Delta t B\) as preconditioner of \(M = Id + \Delta t A\), where \(Id\) is the identity matrix. This can be realized in many ways, e.g., by computing \(K\) as an incomplete factorization of \(M\); in some cases it can be done by solving the linear systems involving \(K\) with fast solvers (FFT or so), see section 3. The RSS approach applies also to linear problems with a matrix \(A(t)\) which depends on time \(t\):

\[
\frac{\partial u}{\partial t} + A(t)u = f,
\]

that we discretize as

\[
(Id + \tau \Delta t B_k) \left( u^{(k+1)} - u^{(k)} \right) = F - A(k\Delta t)u^{(k)}.
\]

The matrix \(K_k\) can be computed as an incomplete LU factorization of \(M = Id + \Delta t A(k\Delta t)\) and, if \(A(t)\) does vary slightly with \(t\), incremental factorization updates from \(K_{k-1}\) can be done following the techniques proposed in [6]. Notice also that scheme (10) can be obtained by applying RSS to linearized equation, as

\[
(Id + \tau \Delta t B_k) \left( u^{(k+1)} - u^{(k)} \right) = -\Delta t F(u^{(k)}),
\]

where \(B_k\) is here such that \(F(u^k) = B_k u^k\).

### 2.2 Properties of the schemes

#### 2.2.1 The linear case

Let \(A\) and \(B\) be both \(N \times N\) real symmetric positive definite matrices; the symmetry of \(A\) is considered for the sake of simplicity however the following approach remains valuable in the nonsymmetric case, see section 3 and Theorem 3.2. We assume that there exist two strictly positive real numbers \(\alpha\) and \(\beta\) such that

\[
\mathcal{H} \quad \quad \alpha < Bu, u > \leq < Au, u > \leq \beta < Bu, u >, \forall u \in \mathbb{R}^N.
\]
It is important to note that $\alpha$ and $\beta$ can depend on the dimension $N$, if not the matrix $B$ is said to be an unconditional preconditioner of $A$. We will use the following notations: $<.,.>$ is the euclidian scalar product in $\mathbb{R}^N$ and $\| . \|$, the associated norm. We will note $\lambda_{\text{min}}$ (resp. $\lambda_{\text{max}}$) the lowest (resp. the largest) eigenvalue of $A$.

We now consider the RSS scheme applied to the discretized heat equation

$$\frac{u^{(k+1)} - u^{(k)}}{\Delta t} + \tau B(u^{(k+1)} - u^{(k)}) = -Au^{(k)}.$$  

We first prove a simple stability result:

**Proposition 2.1** Under hypothesis $\mathcal{H}$, we have the following stability conditions:

- If $\tau \geq \frac{\beta}{2}$, the scheme is unconditionally stable (i.e. stable $\forall \Delta t > 0$)
- If $\tau < \frac{\beta}{2}$, then the scheme is stable for $0 < \Delta t < \frac{2}{(1 - \frac{2\tau}{\beta}) \rho(A)}$.

**Proof.** Taking the usual scalar product of each terms with $u^{(k+1)} - u^{(k)}$, we find

$$\frac{1}{\Delta t} \| u^{(k+1)} - u^{(k)} \|^2 + \tau < B(u^{(k+1)} - u^{(k)}), u^{(k+1)} - u^{(k)} > = -< Au^{(k)}, u^{(k+1)} - u^{(k)} > .$$

Using the parallelogram identity,

$$< Au^{(k)}, u^{(k+1)} - u^{(k)} > = \frac{1}{2} \left( < Au^{(k+1)}, u^{(k+1)} > - < A(u^{(k+1)} - u^{(k)}), u^{(k+1)} - u^{(k)} > \right),$$

we infer

$$\frac{1}{\Delta t} \| u^{(k+1)} - u^{(k)} \|^2 + \tau < B(u^{(k+1)} - u^{(k)}), u^{(k+1)} - u^{(k)} >$$

$$-\frac{1}{2} \left( < Au^{(k)}, u^{(k)} > - < Au^{(k+1)}, u^{(k+1)} > + < A(u^{(k+1)} - u^{(k)}), u^{(k+1)} - u^{(k)} > \right) = 0.$$

Hence the stability condition $< Au^{(k)}, u^{(k)} > < Au^{(k+1)}, u^{(k+1)} >$ holds when

$$\frac{1}{\Delta t} \| u^{(k+1)} - u^{(k)} \|^2 + \tau < B(u^{(k+1)} - u^{(k)}), u^{(k+1)} - u^{(k)} > -\frac{1}{2} < A(u^{(k+1)} - u^{(k)}), u^{(k+1)} - u^{(k)} > > 0.$$

We have, using $\mathcal{H}$

$$\tau < B(u^{(k+1)} - u^{(k)}), u^{(k+1)} - u^{(k)} > -\frac{1}{2} < A(u^{(k+1)} - u^{(k)}), u^{(k+1)} - u^{(k)} > \geq$$

$$\left( \tau - \frac{1}{2} \right) < A(u^{(k+1)} - u^{(k)}), u^{(k+1)} - u^{(k)} > (\geq 0).$$

A sufficient stability condition is then

$$\frac{1}{\Delta t} \| u^{(k+1)} - u^{(k)} \|^2 + \left( \tau - \frac{1}{2} \right) < A(u^{(k+1)} - u^{(k)}), u^{(k+1)} - u^{(k)} > > 0.$$
This is satisfied once $\frac{1}{\Delta t} + \lambda_{\text{min}}(\frac{\tau}{\beta} - \frac{1}{2}) > 0$. Therefore, if $\frac{\tau}{\beta} - \frac{1}{2} \geq 0$ the previous inequality holds for all $\Delta t > 0$, this means the stability $\forall \Delta t > 0$.

Now if $\tau < \frac{\beta}{2}$, then, since $< A(u^{(k+1)} - u^{(k)}) , u^{(k+1)} - u^{(k)} > \leq \rho(A) \| u^{(k+1)} - u^{(k)} \|^2$, a sufficient condition of stability is

$$\frac{1}{\Delta t} + \left( \frac{\tau}{\beta} - \frac{1}{2} \right) \rho(A) > 0,$$

from which we deduce

$$0 < \Delta t < \frac{2}{\left( 1 - 2 \frac{\tau}{\beta} \right) \rho(A)},$$

as a sufficient stability condition. \hfill \blacksquare

We point out that if $B = A$ (then $\alpha = \beta = 1$) and $\tau = \theta \in [0,1]$, the stability condition coincide with the one of the $\theta$-scheme.

The stability is easily obtained when taking $\tau$ large enough. However, a too large value of $\tau$ deteriorates the consistency of the scheme and, as a particular effect, the convergence to the steady state is longer in time. In fact both the value of $\tau$ and the preconditioning quality of $B$ act on the accuracy of the RRS scheme which remains always first order accurate in time as illustrated in Figure 1.

![Figure 1: (left) Influence of the parameter $\tau$ on the accuracy of RSS. Error vs time for different values of $\tau$. $N = 127, \Delta t = 0.004$, (right) Error vs time with ILU(2) and SSOR preconditioners, $N = 63, \tau = 1, \Delta t = 0.004$](image-url)

A first natural question is the choice of the best value $\tau_{\text{opt}}$ of $\tau$, for a fixed preconditioner $B$; $\tau_{\text{opt}}$ can be simply computed such as minimizing $\| \tau B - A \|_F$. We easily show that

$$\tau_{\text{opt}} = \frac{\text{trace}(B^T A)}{\| B \|_F^2}.$$
We remark that when \( B = Id \), then \( \tau_{opt} = \frac{\text{trace}(A)}{n} \), the mean value of the eigenvalues of \( A \).

A second natural question deals with the gain of stability brought by the RSS scheme as respect to an explicit method, namely forward Euler’s for which the time step must be taken strictly lower than \( \Delta t_c = \frac{2}{\rho(A)} \). In other words, for a given preconditioner matrix \( B \) and for a given number \( \tau \), we look to \( \kappa > 1 \) such that RSS is stable with time step \( \Delta t = \kappa \Delta t_c \). We deduce directly from the previous computations.

**Proposition 2.2**  
- If \( \tau \geq \frac{\beta}{2} \), RSS is infinitely more stable than backward Euler’s.
- If \( \tau < \frac{\beta}{2} \), then RSS is at least \( \kappa = \frac{1}{1 - \frac{2\tau}{\beta}} \) times more stable than Euler’s.

**Proof.** We deduce from the proposition 2.1 that \( \left( 1 - \frac{2\tau}{\beta} \right) \rho(A) = \kappa \), then \( \kappa = \frac{1}{1 - \frac{2\tau}{\beta}} \).

We now propose to quantify the consistency error with \( \tau \) by comparison with the Backward Euler Scheme (which is unconditionally stable). Particularly we analyse the behavior of the difference of the sequences generated by the two schemes: the stabilization has as an effect to slow down the convergence in time to the steady state.

**Proposition 2.3** We consider the two sequences

\[
\frac{u^{(k+1)} - u^{(k)}}{\Delta t} + \tau B(u^{(k+1)} - u^{(k)}) = f - A u^{(k)},
\]

and

\[
\frac{v^{(k+1)} - v^{(k)}}{\Delta t} + A v^{(k+1)} = f,
\]

with \( u^{(0)} = v^{(0)} \). We let \( M = Id - \Delta t(Id + \tau \Delta t B)^{-1} A \) and we assume that \( \| M \| < 1 \), then, there exists \( \gamma \in [0, 1[ \) such that

\[
\| u^{(k)} - v^{(k)} \| \leq \Delta t^2 \| \tau B - A \| \frac{1}{1 - \gamma} \| f - A v^{(0)} \|, \forall k \geq 0.
\]

**Proof.** We first remark that \( \| M \| < 1 \) implies the stability of the RSS scheme, since \( M \) is the iteration matrix and \( \rho(M) \leq \| M \| \).

We take the difference and we let \( w^{(k)} = u^{(k)} - v^{(k)} \). We have

\[
\frac{w^{(k+1)} - w^{(k)}}{\Delta t} + \tau B(w^{(k+1)} - w^{(k)}) + (\tau B - A)(v^{(k+1)} - v^{(k)}) = -A w^{(k)}
\]

Hence, after the usual simplifications, we can write

\[
w^{(k+1)} = (Id - \Delta t(Id + \tau \Delta t B)^{-1} A)w^{(k)} - \Delta t(Id + \tau \Delta t B)^{-1}(\tau B - A)(v^{(k+1)} - v^{(k)}),
\]
Using the definition of $M$, we obtain directly the estimate
\[ \| w^{(k+1)} \| \leq M \| w^{(k+1)} \| + \Delta t \| (Id + \tau \Delta t B)^{-1} \| \| \tau B - A \| \| v^{(k+1)} - v^{(k)} \|. \]

We first remark that we have the relations
\[ v^{(k+1)} - v^{(k)} = \Delta t(Id + \Delta t A)^{-1}(f - Av^{(k)}), \]
and
\[ r^{(k+1)} = (Id - \Delta t A)(Id + \Delta t A)^{-1}r^{(k)}, \]
where we have set $r^{(k)} = f - Av^{(k)}$. It follows that
\[ v^{(k+1)} - v^{(k)} = \Delta t(Id + \Delta t A)^{-1}((Id - \Delta t A)(Id + \Delta t A)^{-1})^k r^{(0)}. \]
Then
\[ \| v^{(k+1)} - v^{(k)} \| \leq \Delta t \| (Id + \Delta t A)^{-1} \| \| (Id - \Delta t A)(Id + \Delta t A)^{-1} \| k \| r^{(0)} \|. \]

We set $\gamma = \|(Id - \Delta t A)(Id + \Delta t A)^{-1} \|$, we have of course $\gamma < 1, \forall \Delta t > 0$. A simple induction gives
\[ \| w^{(k+1)} \| \leq M \| w^{(0)} \| + \Delta t^2 \| (Id + \tau \Delta t B)^{-1} \| \| \tau B - A \| \| (Id + \Delta t A)^{-1} \| \| \sum_{j=0}^{k} \gamma^{(j)} \| M \|^{k-j} \| r^{(0)} \|. \]

Using $\| M \| < 1$ and $w^{(0)} = 0$ we find
\[ \| w^{(k+1)} \| \leq \Delta t \| (Id + \tau \Delta t B)^{-1} \| \| \tau B - A \| \Delta t \| (Id + \Delta t A)^{-1} \| \| \sum_{j=0}^{k} \gamma^{(j)} \| r^{(0)} \|. \]

Hence
\[ \| w^{(k+1)} \| \leq \Delta t^2 \| \tau B - A \| \frac{1}{1 - \gamma} \| r^{(0)} \|, \]
which shows the dependence on $\| \tau B - A \|$. Of course if $\tau = 1$ and $B = A$ we have $w^{(k)} = 0, \forall k$. Hence the result. \[ \blacksquare \]

We deduce immediately the

**Corollary 2.4** The RSS method is first order accurate.

**Proof.** It suffices to own that the Backward Euler method is first order accurate. \[ \blacksquare \]

We now will consider the particular the case in which $B$ is a diagonal matrix. This choice allows a fast solution of the implicit part of RSS, the matrix $Id + \tau \Delta t B$ being also diagonal. In general situations, a diagonal preconditioner is not the most efficient, but in some cases, e.g. when the discrete problem in written in hierarchical-like bases, it is particularly interesting to consider $B$ as a diagonal matrix: A. Cohen et al [1] have introduced the RSS scheme for a
problem discretized in a wavelet basis, in which the diagonal part of the stiffness matrix is an
inconditional preconditioner; this was independently applied by Costa et al [10, 11] using Fourier
and Chebyshev expansions and then in finite differences with incrementals unknowns by Chehab
and Costa [7, 8, 9]. The underlying idea is to decompose the unknowns $U$ of the nodal basis
into a hierarchy of arrays of details at different levels ($\hat{U}_0, \hat{U}_1, \cdots, \hat{U}_d)^T$; here $\hat{U}_0$ is associated to
a coarse discretization and then captures only low frequencies while the other set of components
$\hat{U}_j, \quad j = 1, \cdots, d$ are details associated to refinement of the coarse approximation space and cap-
ture high frequencies.
The time limitation of the explicit schemes for parabolic problems depends on its capability
to contain high frequencies expansions. In Fourier-like basis, the details attached to high fre-
quencies are small quantities regardless to the details attached to low frequencies since they
contribute residually to the energy norm of the signal. As proposed in [11, 7, 8] this situation
allows to damp differently the high and the low frequencies components without deterioring the
consistency of the scheme.

Consider for instance the heat equation

$$u_t - u_{xx} = f,$$

that we discretize in time with the forward Euler scheme as

$$\frac{u^{(k+1)} - u^{(k)}}{\Delta t} - u_{xx}^{(k)} = f.$$

In [10, 11], this scheme was proposed to be stabilized as

$$\frac{u^{(k+1)} - u^{(k)}}{\Delta t} + \beta \frac{u^{(k+1)} - u^{(k)}}{\Delta t} - u_{xx}^{(k)} = f.$$

Considering a Fourier discretization, we find, after simplifications

$$\frac{\hat{u}_m^{(k+1)} - \hat{u}_m^{(k)}}{\Delta t} - \beta \frac{\hat{u}_m^{(k+1)} - \hat{u}_m^{(k)}}{\Delta t} = -k^2 \hat{u}_m^{(k)} + \hat{f}_m, \quad m = 1, \cdots, N.$$

If we decompose the frequency range $[1, N]$ into $\cup_{j=1}^d [N_{j-1}, N_j]$, the above scheme can be applied
to each range with a different stabilizing parameter $\beta_j$, so we obtain, for $j = 1, \cdots, d$

$$\frac{\hat{u}_m^{(k+1)} - \hat{u}_m^{(k)}}{\Delta t} - \beta_j \frac{\hat{u}_m^{(k+1)} - \hat{u}_m^{(k)}}{\Delta t} = -m^2 \hat{u}_m^{(k)} + \hat{f}_m, \quad m = N_{j-1}, \cdots, N_j.$$

Letting $\tilde{\beta}_i = \frac{\beta_i}{\Delta t}$, the last scheme is rewritten as

$$\hat{u}_m^{(k+1)} = \left(1 - \frac{m^2 \Delta t}{1 + \Delta t \tilde{\beta}_j}\right) \hat{u}_m^{(k)} + \frac{\Delta t}{1 + \Delta t \tilde{\beta}_j} \hat{f}_m, \quad m = N_{j-1}, \cdots, N_j.$$

The stability condition is then

$$(m^2 - 2\tilde{\beta}_j) \Delta t < 2, m = N_{j-1}, \cdots, N_j.$$
The scheme is unconditionally stable at level \( j \) if \( \tilde{\beta}_j \geq \frac{N^2_{j+1}}{2(j+1)} \) and stable under condition \( 0 < \Delta t < \frac{2}{N^2_{j+1} - 2\tilde{\beta}_j} \) otherwise. This condition is of course similar to that found in Proposition 2.1.

Now, considering all the components, we write
\[
\hat{u}^{(k+1)} - \hat{u}^{(k)} = \frac{\Delta t}{\tilde{\beta}_j} - B(\hat{u}^{(k+1)} - \hat{u}^{(k)}) = -D\hat{u}^{(k)} + \hat{f},
\]
with \( D = \text{diag}(1, 4, 9, \cdots N^2) \) and
\[
B = \begin{pmatrix}
B_1 & 0 & 0 \\
0 & \ddots & \ddots \\
0 & \cdots & B_d
\end{pmatrix},
\]
where \( B_j = \beta_j I_{d_j} \), \( I_{d_j} \) being the identity matrix of size \((N_j - N_{j-1}) \times (N_j - N_{j-1})\) (we have set \( N_0 = 0 \) and \( N_d = N \)).

\( B \) is then a preconditioner of \( D \) in the Fourier space; in the linear case, these two approaches coincide. Costa and Chehab [7, 8] have extended this scheme to hierarchical discretizations in finite differences.

Note that this framework allows to damp high frequencies and to leave unchanged the low ones changing only slightly the consistency of the scheme while increasing its stability. This can be done typically by taking \( \beta_j = 0 \) on the low frequencies components and \( \beta_j >> 1 \) on the high ones.

As stated in the introduction, we concentrate on problems discretized in the nodal basis, however, it is useful to make the link with the hierarchical approach. We give a block version of Proposition 2.1.

We assume that the stiffness matrix \( A \) written in a detail basis possesses the following block decomposition
\[
A = \begin{pmatrix}
A_{1,1} & A_{1,2} & \cdots & A_{d,d} \\
A_{2,1} & & & \\
\vdots & & & \\
A_{d,1} & \cdots & A_{d,d}
\end{pmatrix}.
\]

We note the corresponding block decomposition of a vector \( U \) as \( U = (u_1, \cdots, u_d)^T \). We have the

**Theorem 2.5** A sufficient stability condition is
\[
\frac{1}{\Delta t} + \tau \beta_i - \frac{1}{4} \left( \sum_{j=1}^{d} \| A_{i,j} \| + \| A_{j,i} \| \right) > 0, i = 1, \cdots, d.
\]

**Proof.** Taking the scalar product of the equation with \( U^{(k+1)} - U^{(k)} \), we find
\[
\frac{1}{\Delta t} \| U^{(k+1)} - U^{(k)} \|^2 + \tau < B(U^{(k+1)} - U^{(k)}), U^{(k+1)} - U^{(k)} > + \frac{1}{2} \left( < AU^{(k)}, U^{(k)} > - < AU^{(k+1)}, U^{(k+1)} > + < A(U^{(k+1)} - U^{(k)}), U^{(k+1)} - U^{(k)} > \right) = 0,
\]

11
and using the block decomposition

\[
\sum_{i=1}^{d} \frac{1}{\Delta t} \left\| u_i^{(k+1)} - u_i^{(k)} \right\|^2 + \tau \beta_i \left\| u_i^{(k+1)} - u_i^{(k)} \right\|^2
\]

\[-\frac{1}{2} \left( <U^{(k)}, U^{(k)}> - <U^{(k+1)}, U^{(k+1)}> \right) + \frac{1}{2} \sum_{i=1}^{d} \sum_{j=1}^{d} <A_{i,j} (u_j^{(k+1)} - u_j^{(k)}), u_i^{(k+1)} - u_i^{(k)}> = 0.
\]

A sufficient condition for the energy stability is then

\[
\sum_{i=1}^{d} \frac{1}{\Delta t} \left\| u_i^{(k+1)} - u_i^{(k)} \right\|^2 + \tau \beta_i \left\| u_i^{(k+1)} - u_i^{(k)} \right\|^2 - \frac{1}{2} \sum_{i=1}^{d} \sum_{j=1}^{d} <A_{i,j} (u_j^{(k+1)} - u_j^{(k)}), u_i^{(k+1)} - u_i^{(k)}> > 0.
\]

Since,

\[
-\frac{1}{2} \sum_{i=1}^{d} \sum_{j=1}^{d} <A_{i,j} (u_j^{(k+1)} - u_j^{(k)}), u_i^{(k+1)} - u_i^{(k)}> \geq -\frac{1}{2} \sum_{i=1}^{d} \sum_{j=1}^{d} \|A_{i,j}\| \left\| u_i^{(k+1)} - u_i^{(k)} \right\| \left\| u_j^{(k+1)} - u_j^{(k)} \right\|
\]

\[
\geq -\frac{1}{4} \sum_{i=1}^{d} \sum_{j=1}^{d} \|A_{i,j}\| \left\| u_j^{(k+1)} - u_j^{(k)} \right\|^2
\]

\[
-\frac{1}{2} \sum_{i=1}^{d} \sum_{j=1}^{d} \|A_{i,j}\| \left\| u_i^{(k+1)} - u_i^{(k)} \right\|^2
\]

\[
= -\frac{1}{4} \sum_{i=1}^{d} \left( \sum_{j=1}^{d} \|A_{i,j}\| + \|A_{j,i}\| \right)
\]

We find as sufficient stability condition

\[
\sum_{i=1}^{d} \left( \frac{1}{\Delta t} + \tau \beta_i - \frac{1}{4} \left( \sum_{j=1}^{d} \|A_{i,j}\| + \|A_{i,j}\| \right) \right) \left\| u_i^{(k+1)} - u_i^{(k)} \right\|^2 > 0.
\]

In particular, if \( \tau \beta_i \geq \frac{1}{4} \left( \sum_{j=1}^{d} \|A_{i,j}\| + \|A_{j,i}\| \right) > 0 \), the stability is unconditional.

It has to be noted that when \( d = 1 \) and \( B = \text{Id} \), we recover the result given by Proposition 2.1.

We infer also that, the extradiagonal coefficients of stiffness matrices in hierarchical-like basis enjoy of a decreasing magnitude properties far from the diagonal making successful the approach.

If we consider Fourier basis, the stiffness matrix \( A \) is diagonal and the stability condition at range \( j \) is

\[(m^2 - 2\tilde{\beta}_j)\Delta t < 2, m = N_{j-1}, \cdots, N_j\]

so, taking \( \beta_j = \frac{N_{j+1}^2}{2} \), we have an incondiditionally stable RSS scheme.
2.2.2 The nonlinear case

We aim at applying the RSS Scheme to reaction-diffusion equation (such as Allen-Cahn’s, see section 4) say

\[ \frac{\partial u}{\partial t} - \Delta u + \frac{1}{\epsilon^2} f(u) = 0, \quad x \in \Omega, \ t > 0, \]  
\[ \frac{\partial u}{\partial n} = 0 \quad \partial \Omega, \ t >, \]  
\[ u(x, 0) = u_0(x) \quad x \in \Omega. \]  

(11)

The RSS scheme applied to the discretized scheme reads as

\[ \frac{u^{(k+1)} - u^{(k)}}{\Delta t} + \tau B(u^{(k+1)} - u^{(k)}) + \frac{1}{\epsilon^2} f(u^{(k)}) = -Au^{(k)} \]  

(14)

We set \( E(u) = \frac{1}{2} < Au, u > + \frac{1}{\epsilon^2} < F(u), 1 > \), where \( F \) is a primitive of \( f \) that we choose such that \( F(0) = 0 \). We say that the scheme is energy decreasing if

\[ E(u^{(k+1)}) < E(u^{(k)}) \]

Particularly, if \( F \) as nonnegative values, the scheme will be stable for the norm \( |u|_A = \sqrt{<Au,u>} \).

**Theorem 2.6** Assume that \( f \) is \( \mathcal{C}^1 \) and \( |f'|_{\infty} \leq L \). We have the following stability conditions

- **If \( \tau \geq \frac{\beta}{2} \)** then
  - if \( \left( \frac{\tau}{\beta} - \frac{1}{2} \right) \lambda_{\text{min}} - \frac{L}{2\epsilon^2} \geq 0 \) then the scheme is unconditionally stable
  - if \( \left( \frac{\tau}{\beta} - \frac{1}{2} \right) \lambda_{\text{min}} - \frac{L}{2\epsilon^2} < 0 \) then the scheme is table for

  \[ 0 < \Delta t < \frac{1}{\frac{L}{2\epsilon^2} - \left( \frac{\tau}{\beta} - \frac{1}{2} \right) \lambda_{\text{min}}} \]

- **If \( \tau < \frac{\beta}{2} \)** then the scheme is table for

  \[ 0 < \Delta t < \frac{1}{\frac{L}{2\epsilon^2} - \left( \frac{\tau}{\beta} - \frac{1}{2} \right) \rho(A)} \]

**Proof.** We have, taking the scalar product in \( \mathbb{R}^N \) of each element of the with \( u^{(k+1)} - u^{(k)} \):

\[ \frac{1}{\Delta t} \| u^{(k+1)} - u^{(k)} \|^2 + \tau < B(u^{(k+1)} - u^{(k)}), u^{(k+1)} - u^{(k)} > = -\frac{1}{\epsilon^2} < f(u^{(k)}), u^{(k+1)} - u^{(k)} > \]

\[ - < Au^{(k)}, u^{(k+1)} - u^{(k)} >. \]
Let us now consider the nonlinear term. We have using Taylor-Lagrange’s expansion

\[ F(u_i^{(k+1)}) - F(u_i^{(k)}) = f(u_i^{(k)})(u_i^{(k+1)} - u_i^{(k)}) + \frac{1}{2} f'(\xi_i)(u_i^{(k+1)} - u_i^{(k)})^2. \]

Taking the sum of these term for \( i = 1, \ldots, N \), we obtain

\[ < F(u^{(k+1)}, 1) > - < F(u^{(k)}, 1) > = < f(u^{(k)}), u^{(k+1)} - u^{(k)} > + \frac{1}{2} \sum_{i=1}^{N} f'(x_i)(u_i^{(k+1)} - u_i^{(k)})^2. \]

so that

\[ -\frac{1}{\epsilon^2} f(u^{(k)}, u^{(k+1)} - u^{(k)}) \leq -\frac{1}{\epsilon^2} ( < F(u^{(k+1)}, 1) > - < F(u^{(k)}, 1) > ) + \frac{L}{2 \epsilon^2} \| u^{(k+1)} - u^{(k)} \| ^2. \]

The other terms are treated exactly as in the linear case, and we use the identity

\[ < Au^{(k)}, u^{(k+1)} - u^{(k)} > = \frac{1}{2} \left( < Au^{(k+1)}, u^{(k+1)} > - < A(u^{(k)}), u^{(k+1)} > + < A(u^{(k+1)} - u^{(k)}), u^{(k+1)} - u^{(k)} > \right). \]

Making use of these results, we find, after the usual simplifications

\[ \left( \frac{1}{\Delta t} - \frac{L}{2 \epsilon^2} \right) \| u^{(k+1)} - u^{(k)} \| ^2 + \left( \frac{\tau}{\beta} - \frac{1}{2} \right) < A(u^{(k+1)} - u^{(k)}), u^{(k+1)} - u^{(k)} > + E(u^{(k+1)}) - E(u^{(k)}) \leq 0 \]

Hence the stability is obtained when

\[ \left( \frac{1}{\Delta t} - \frac{L}{2 \epsilon^2} \right) \| u^{(k+1)} - u^{(k)} \| ^2 + \left( \frac{\tau}{\beta} - \frac{1}{2} \right) < A(u^{(k+1)} - u^{(k)}), u^{(k+1)} - u^{(k)} > > 0. \]

Hence the result. 

We point out that in the linear case (\( f = 0 \) and \( L = 0 \)), we recover the stability conditions given by proposition 2.1.

As an application, we can consider the simulation of the Allen-Cahn equation

\[ \frac{\partial u}{\partial t} - \Delta u + \frac{1}{\epsilon^2} f(u) = 0 \quad x \in \Omega, t > 0, \quad \frac{\partial u}{\partial n} = 0 \quad x \in \partial \Omega, \forall t > 0, \]

\[ u(x, 0) = u_0(x) \quad x \in \Omega. \]

This reaction-diffusion equation describes the process of phase separation in many situations, \cite{17}. In practice, we will chose \( f(u) = u(u^2 - 1) \).

Notice that Shen et al \cite{18} have proposed the scheme

\[ \frac{u^{(k+1)} - u^{(k)}}{\Delta t} + \frac{S}{\epsilon^2} (u^{(k+1)} - u^{(k)}) + Au^{(k+1)} + \frac{1}{\epsilon^2} f(u^{(k)}) = 0. \]

With Theorem 2.6 we recover the stability conditions proposed by J. Shen when \( A = B \) and \( \tau = 1 \) and \( S = 0 \); The term \( \frac{S}{\epsilon^2} (u^{(k+1)} - u^{(k)}) \) plays the role of the stabilizator, following the

14
same principle as the schemes introduced in [10, 11]. The time restriction become harder when \( \epsilon \) takes small values. This situation motivates the use of stabilized schemes. Now, if \( S > \frac{L}{\tau} \), the scheme [18] is unconditionally stable. This is to be compared with the RSS scheme [14]. We find as unconditional stability condition

\[
\tau > \frac{\beta L}{2\lambda_{\text{min}}} + \frac{\beta \epsilon^2}{2},
\]

which is a comparable condition for \( \epsilon \) small enough and \( \beta \) bounded, since in practice \( \lambda_{\text{min}} \) is a positive constant which not depend on the dimension of the problem, the first eigenvalue of the stiffness matrix is indeed nicely captured by the discretization schemes. However the additional stabilizing terms can deteriorate the consistency.

2.3 Richardson extrapolation

In [1] the authors have proposed to increase the accuracy of the stabilized scheme by smoothing the residual using a Richardson extrapolation process:

The solution of

\[
\frac{du}{dt} = F(u),
\]

by the forward Euler scheme defines the iterations

\[
u^{k+1} = u^k + \Delta t F(u^k) = G_{\Delta t}(u^k).
\]

The smoothed sequence is defined by

\[
\begin{align*}
v_1 &= G_{\Delta t}(u^k), \\
v_{2,0} &= G_{\Delta t/2}(u^k), \\
v_{2,1} &= G_{\Delta t/2}(v_{2,0}), \\
u^{k+1} &= 2v_{2,1} - v_1.
\end{align*}
\]

It is second order accurate in time. The accuracy of the stabilized scheme is increased by applying the extrapolation to the iteration operator

\[
G_{\Delta t,\tau}(u^k) = u^k + \Delta t(\text{Id} + \tau \Delta t B)^{-1} F(u^k).
\]

The improvement is studied analytically in [17], but numerical evidences point out the efficiency of the approach, see also the numerical results presented in Section 4.

Below the Extrapoled RSS scheme
Algorithm 1: Extrapoled RSS Scheme

3 Discretisation in space and preconditioning

3.1 Compact FD Scheme Discretization

A way to obtain a high level of accuracy with a finite difference scheme, that can be compared with the spectral one, is to implement finite difference compact schemes [14]. These schemes consist in approaching a linear operator (differentiation, interpolation) by a rational (instead of polynomial-like) finite differences scheme. We describe briefly here only their construction for the approximation of the first and the second derivative and we refer to [14] for more details. We first consider the schemes in space dimension one.

Let \( U = (U_1, \ldots, U_n)^T \) denotes a vector whose the components are the approximations of a regular function \( u \) at (regularly spaced) grid points \( x_i = ih, \ i = 1, \ldots, n \). We compute approximations of \( V_i = L(u)(x_i) \) as solution of a system

\[ PV = QU, \]

so the approximation matrix is formally \( B = P^{-1}Q \). When \( P = Id \), the scheme is explicit and we recover the framework of classical finite difference schemes; when \( P \neq Id \), the scheme is implicit and it is possible to reach high order accuracy, the implicitity allows to mimic the spectral global dependence. In practice, \( P \) is a banded sparse matrix easy to invert and very well conditioned making the compact scheme approach robust and not costly regardless to the precision brought. We here give the matrices \( P \) and \( Q \) for the fourth order approximation of the first and the second derivative, details can be found in [14].

Let us begin with the first derivative. We have

\[
P = \begin{pmatrix}
1 & \frac{1}{4} & \frac{1}{4} & \frac{1}{4} \\
\frac{1}{4} & 1 & \cdots & \frac{1}{4} \\
\frac{1}{4} & \cdots & \cdots & \frac{1}{4} \\
\frac{1}{4} & \cdots & \cdots & 1
\end{pmatrix},
\]
\[ Q = \frac{1}{2h} \begin{pmatrix} a_1 & a_2 & a_3 & a_4 \\ -\frac{3}{2} & 0 & \frac{3}{2} & \\ \vdots & \vdots & \vdots & \vdots \\ -\frac{3}{2} & 0 & \frac{3}{2} & \\ -a_4 & -a_3 & -a_2 & -a_1 \end{pmatrix}, \]

with \( a_1 = -2, a_2 = 3, a_3 = -\frac{2}{3} \) and \( a_4 = \frac{1}{8} \).

In the same way, we can build the fourth order compact schemes for the second order derivative. We first consider the compact scheme associated to the discretization of the second derivative with homogeneous Dirichlet boundary conditions. We have

\[ P = \begin{pmatrix} 1 & \frac{1}{10} & \frac{1}{10} \\ \frac{1}{10} & 1 & \frac{1}{10} \\ \vdots & \vdots & \vdots \\ \frac{1}{10} & \frac{1}{10} & 1 \end{pmatrix}, \]

and

\[ Q = \frac{1}{h^2} \begin{pmatrix} a_1 & a_2 & a_3 & a_4 & a_5 \\ -\frac{6}{5} & \frac{12}{5} & -\frac{6}{5} & -\frac{6}{5} & \\ -\frac{6}{5} & \frac{12}{5} & -\frac{6}{5} & -\frac{6}{5} & \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ -\frac{6}{5} & \frac{12}{5} & -\frac{6}{5} & -\frac{6}{5} & \\ a_{N-4} & a_{N-3} & a_{N-2} & a_{N-1} & a_N \end{pmatrix}, \]

here the constant \( a_1, a_2, a_3, \ldots \) are given by

\[
\begin{cases}
    a_1 &= a_N = \frac{-67}{60}, \\
    a_2 &= a_{N-1} = \frac{-1}{12}, \\
    a_3 &= a_{N-2} = \frac{13}{10}, \\
    a_4 &= a_{N-3} = \frac{-61}{120}, \\
    a_5 &= a_{N-4} = \frac{1}{12}.
\end{cases}
\]

Now applying the same approach, we can consider fourth order compact schemes for the second derivative with associated homogeneous Neumann Boundary conditions

\[ M = \begin{pmatrix} 1 & \frac{1}{10} & \frac{1}{10} \\ \frac{1}{10} & 1 & \frac{1}{10} \\ \vdots & \vdots & \vdots \\ \frac{1}{10} & \frac{1}{10} & 1 \end{pmatrix}, \]

17
and

\[ N = \frac{1}{h^2} \begin{pmatrix} a_1 & a_2 & a_3 & a_4 & a_5 \\ 6/5 & 12/5 & 6/5 & -6/5 & -6/5 \\ -6/5 & 12/5 & -6/5 & -6/5 & -6/5 \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ a_{N-4} & a_{N-3} & a_{N-2} & a_{N-1} & a_N \end{pmatrix}, \]

with

\[
\begin{align*}
a_1 &= a_N = \frac{2681}{480}, \\
a_2 &= a_{N-1} = \frac{-13}{40}, \\
a_3 &= a_{N-2} = \frac{113}{40}, \\
a_4 &= a_{N-3} = \frac{-13}{15}, \\
a_5 &= a_{N-4} = \frac{59}{480}.
\end{align*}
\]

To obtain the compact schemes of first and second order derivative in space dimension 2 and 3, it suffices to use the previous schemes and to expand them tensorally.

The finite differences discretization matrices of derivative on cartesian domains can be obtained by those on the interval using Kronecker products. Indeed, if \( A_{xx}^N \) denotes the discretization matrix on \([0, 1]\) associated to Dirichlet Boundary conditions, using \( N \) internal discretization points, then

\[ \text{Id}_M \otimes A_{xx}^N \]

will be the discretization matrix of the same operator but on a grid composed of \( N \times M \) points, the corresponding laplacian matrix will be \( A_{xx}^M \otimes \text{Id}_N + \text{Id}_M \otimes A_{xx}^N \). We recall that the Kronecker product of a \( m \times n \) matrix \( A \) by a \( p \times q \) matrix \( B \) is defined as

\[ A \otimes B = \begin{pmatrix} a_{11}B & \cdots & a_{1n}B \\ \vdots & \ddots & \vdots \\ a_{m1}B & \cdots & a_{mn}B \end{pmatrix}. \]

### 3.2 Preconditioning FD Compact schemes using second order FD

The matrices associated to compact finite difference schemes are full, this is due to the implicit nature of the scheme. A natural idea to build a sparse preconditioner is to use the matrix obtained by applying a lower accurate finite discretization scheme, particularly a second order one. We here describe the approach for one dimensional problem, extensions to higher dimensions are obtained using kronecker products, also we restrict to linear problem for simplicity. Let \( A_2 \) (resp \( A_4 \)) be the second order (resp. the fourth order) discretization matrix of \(-\Delta\) on a regular grid composed of \( N \) internal points. The RSS scheme writes as

\[
\frac{u^{(k+1)} - u^{(k)}}{\Delta t} + \tau A_2 (u^{(k+1)} - u^{(k)}) + A_4 u^{(k)} = f. \tag{19}
\]
The numerical treatment of non homogeneous (possibly time depending) Dirichlet boundary conditions can be realized with the RSS approach. Indeed, let us note $A_m(u,n), m = 2, 4$, the $m$th order finite difference discretization of $-\Delta$ of $u$ with Dirichlet conditions at time $n\Delta t$, note that this operator is affine. The stabilized scheme writes formally as

$$\frac{u^{(k+1)} - u^{(k)}}{\Delta t} + \tau (A_2(u^{(k+1)}, k+1) - A_2(u^{(k)}, k)) + A_4(u^{(k)}, k) = f,$$  \hspace{1cm} (20)

Making the approximation $A_2(u^{(k+1)}, k+1) \simeq A_2(u^{(k+1)}, k)$, we obtain

$$\frac{u^{(k+1)} - u^{(k)}}{\Delta t} + \tau A_2(u^{(k+1)} - u^{(k)}) + A_4(u^{(k)}, k) = f.$$  \hspace{1cm} (21)

It is to be pointed out that for the solutions of 2D and 3D Poisson problems, the number of iterations to the convergence is not dependent on the dimension of the system. Also, in the case of Poisson-like problem, we can use FFT to solve the preconditioning system, speeding up the resolution of the original linear system. This approach will be followed also for the fast solution of the heat equation that arises in parabolic problems.

Remark 3.1 A analogous approach have been done in the context of hierarchical preconditioners in finite differences, where the fourth order discretization matrix of $-\Delta$ was preconditioned by the hierarchical transfert matrix attached to the second order accurate discretization of $-\Delta$, see [5].

Below, we report numerical results on the solution of 2D and 3D Poisson problems when discretized by fourth order compact schemes. The preconditioning matrix is obtained by applying corresponding second order finite difference schemes. We took a random r.h.s $b=1-2\times\text{rand}(N,1)$ so that many frequencies including high ones are present. The initial data is $u = 0$, the tolerance parameter $10^{-12}$. The result we report is the maximum number of external iterations to convergence, on 5 independent numerical resolutions, the number of discretization point per direction $n$ is reported as $(n)$. The stiffness matrices are then of respective sizes $n^2 \times n^2$ (2D problem) and $n^3 \times n^3$ (3D problem).

| Problem     | # it. (n) | # it. (n) | # it. (n) | # it. (n) | # it. (n) | # it. (n) |
|-------------|-----------|-----------|-----------|-----------|-----------|-----------|
| Poisson 2D  | 12 (n=15) | 11 (n=31) | 10 (n=63) | 10 (n=127)| 9 (n=255) | 8 (n=511) |
| Poisson 3D  | 12 (n=15) | 11 (n=31) | 11 (n=63) |           |           |           |

Table 1: Solutions of 2D and 3D Poisson problem with GMRES and second order preconditioner

Here, the fourth order discretization matrix $A$ of $-\Delta$ is nonsymmetric while the preconditioning matrix $B$ is. However, in practice the RSS method is still efficient. This is due to the small size of the skewsymmetric part of $A$. Indeed, denoting by $\delta = \| A - A^T \|$, we can prove the following general stability result.

Theorem 3.2 Let $A \in \mathcal{M}_n(\mathbb{R}^N)$. We assume that $A$ is positive definite and $B$ a symmetric definite positive preconditioning matrix of $A$ satisfy hypothesis $\mathcal{H}$. We set $\delta = \| A - A^T \|$ and
\[ \Phi(\xi) = (\beta^2 - 2\alpha\tau)\xi + \frac{1}{4\xi}\delta^2. \] Assume that \[ \frac{\beta^2}{2\alpha} - \frac{\delta^2}{8\alpha\lambda\min(B)^2} \geq 0. \] Then the RSS scheme has the following stability conditions

i. if \( \tau \geq \frac{\beta^2}{2\alpha} + \frac{\delta^2}{8\alpha\lambda\min(B)} \geq \frac{\beta^2}{2\alpha} \) then the scheme is unconditionally stable.

ii. If \( \tau \leq \frac{\beta^2}{2\alpha} - \frac{\delta^2}{8\alpha\lambda\max(B)^2} \) then the scheme is stable under condition

\[ 0 < \Delta t < \frac{2\alpha}{\Phi(\lambda\max(B))}. \]

iii. If \( \frac{\beta^2}{2\alpha} - \frac{\delta^2}{8\alpha\lambda\max(B)^2} \leq \tau < \frac{\beta^2}{2\alpha} - \frac{\delta^2}{8\alpha\lambda\min(B)^2} \) then the scheme is stable under condition

\[ 0 < \Delta t < \frac{2\alpha}{\Phi(\lambda\min(B))}. \]

iv. If \( \tau \leq \frac{\beta^2}{2\alpha} - \frac{\delta^2}{8\alpha\lambda\min(B)^2} \) then the scheme is stable under condition

\[ 0 < \Delta t < \frac{2\alpha}{\max(\Phi(\lambda\min(B)), \Phi(\lambda\max(B)))}. \]

Here \( \lambda\min(B) \) (resp. \( \lambda\max(B) \)) denotes the lowest (resp. the largest) eigenvalue of \( B \).

**Proof.** The RSS scheme reads as

\[ u^{(k+1)} = u^{(k)} - \Delta t (Id + \tau\delta t B)^{-1} A u^{(k)} = M u^{(k)}, \]

and is stable under the necessary and sufficient condition \( \rho(M) < 1 \); in the general case the eigenvalues of \( M \) can be complex. Let \( v \in \mathbb{C}^N \) be an eigenvector of \( M \) associated to the eigenvalue \( \lambda = a + ib \). We have

\[ \lambda v = M v, \text{ so } (1 - \lambda) (Id + \tau\delta t B) v = \Delta t A v. \]

We decompose \( v = v_1 + iv_2 \) and, separating real and imaginary parts, we obtain

\[ Av_1 = \frac{1-a}{\Delta t} (v_1 + \tau\Delta t Bv_1) + \frac{b}{\Delta t} (v_2 + \tau\Delta t Bv_2), \]

\[ Av_1 = \frac{1-a}{\Delta t} (v_2 + \tau\Delta t Bv_2) - \frac{b}{\Delta t} (v_1 + \tau\Delta t Bv_1). \]

We have then, on the one hand

\[ < Av_1, v_1 > + < Av_2, v_2 > = \frac{1-a}{\Delta t} \left( \| v_1 \|^2 + \| v_2 \|^2 + \tau \Delta t < B v_1, v_1 > + \tau \Delta t < B v_2, v_2 > \right), \]

and, on the other hand,

\[ < Av_1, v_2 > - < Av_2, v_1 > = \frac{b}{\Delta t} \left( \| v_1 \|^2 + \| v_2 \|^2 + \tau \Delta t < B v_1, v_1 > + \tau \Delta t < B v_2, v_2 > \right). \]
We now set for convenience \( N(v_1, v_2) = \| v_1 \|^2 + \| v_2 \|^2 + \tau \Delta t < B v_1, v_1 > + \tau \Delta t < B v_2, v_2 > \).

We infer from the previous identities

\[
a = 1 - \Delta t \frac{N(v_1, v_2)}{N(v_1, v_2)} ( < A v_1, v_1 > + < A v_2, v_2 >) \quad \text{and} \quad b = \Delta t \frac{N(v_1, v_2)}{N(v_1, v_2)} (A - A^T) v_1, v_2 >.
\]

The stability condition is

\[
\eta = a^2 + b^2 < 1. \tag{22}
\]

After the usual simplifications, we find as a sufficient condition

\[
\eta \leq 1 - 2 \frac{\Delta t}{N(v_1, v_2)} \alpha ( < B v_1, v_1 > + < B v_2, v_2 >) + \frac{\Delta t^2}{N(v_1, v_2)^2} \beta^2 ( < B v_1, v_1 > + < B v_2, v_2 >)^2
\]

\[
+ \frac{\Delta t^2}{4N(v_1, v_2)^2} \| A - A^T \|^2 (\| v_1 \|^2 + \| v_2 \|^2)^2.
\]

We now let \( Z = < B v_1, v_1 > + < B v_2, v_2 > \) and \( Y = \| v_1 \|^2 + \| v_2 \|^2 \). The last inequality reads

\[
\Delta t \left( (\beta^2 - 2\alpha \tau) Z^2 + \frac{1}{4} \| A - A^T \|^2 Y^2 \right) < 2\alpha Y Z.
\]

At this point, we set \( \xi = \frac{Z}{Y} = \frac{< B v_1, v_1 > + < B v_2, v_2 >}{\| v_1 \|^2 + \| v_2 \|^2} \). Note that we have \( \lambda_{\min}(B) \leq \xi \leq \lambda_{\max}(B) \). After usual simplifications, the sufficient stability condition \([22]\) writes now as

\[
\Delta t \left( (\beta^2 - 2\alpha \tau) \xi^2 + \frac{1}{4} \delta^2 \frac{\xi}{\xi} \right) \xi < 2\alpha,
\]

where we have set \( \delta = \| A - A^T \| \). We use the function \( \Phi(\xi) = (\beta^2 - 2\alpha \tau) \xi^2 + \frac{1}{4} \delta^2 \frac{\xi}{\xi} \). \( \Phi \) is obviously regular on \( [\lambda_{\min}(B), \lambda_{\max}(B)] \), since \( \lambda_{\min}(B) > 0 \), \( B \) is assumed to be SPD. We deduce the following sufficient stability conditions

- if \( \Phi(\xi) \leq 0, \forall \xi \in [\lambda_{\min}(B), \lambda_{\max}(B)] \), the scheme is unconditionnaly stable
- if there exists \( \xi \in [\lambda_{\min}(B), \lambda_{\max}(B)] \) such that \( \Phi(\xi) > 0 \), then a sufficient stability condition is

\[
0 < \Delta t < \frac{2\alpha}{\text{Max}_{\xi \in [\lambda_{\min}(B), \lambda_{\max}(B)]} \Phi(\xi)}.
\]

We conclude by studying the two cases.

Unconditional stability : To have \( \Phi(\xi) \leq 0, \forall \xi \in [\lambda_{\min}(B), \lambda_{\max}(B)] \), we must have \( \Phi(\lambda_{\min}(B)) \leq 0 \) and \( \Phi(\lambda_{\max}(B)) \leq 0 \), that is

\[
\tau \geq \frac{\beta^2}{2\alpha} + \frac{\delta^2}{8\alpha \lambda^2_{\min}(B)} \geq \frac{\beta^2}{2\alpha}.
\]
We now remark that $\Phi'(\xi) = (\beta^2 - 2\alpha \tau) - \frac{\delta^2}{4\xi^2} \leq 0 \iff \tau \geq \frac{\beta^2 - \delta^2}{2\alpha - 8\alpha \xi^2}, \forall \xi \in [\lambda_{\min}(B), \lambda_{\max}(B)]$.

This is satisfied under the previous hypothesis, hence the first statement [1] of the theorem.

Conditional stability: The condition is $\max(\Phi(x)) > 0$. We distinguish two cases

- $\Phi'(\xi) \geq 0$ and $\Phi(\lambda_{\max}(B)) > 0$ ie $\tau < \frac{\beta^2}{2\alpha} - \frac{\delta^2}{8\alpha \lambda_{\max}(B)^2}$ and $\tau \leq \frac{\beta^2}{2\alpha} - \frac{\delta^2}{8\alpha \lambda_{\max}(B)^2}$.

A sufficient stability condition is then $\tau \leq \frac{\beta^2}{2\alpha} - \frac{\delta^2}{8\alpha \lambda_{\max}(B)^2}$ and

$0 < \Delta t < \frac{2\alpha}{\Phi(\lambda_{\max})}$,

- $\Phi'(\xi) \leq 0$ and $\Phi(\lambda_{\min}(B)) > 0$ that is $\frac{\beta^2}{2\alpha} - \frac{\delta^2}{8\alpha \lambda_{\max}(B)^2} \leq \tau < \frac{\beta^2}{2\alpha} + \frac{\delta^2}{8\alpha \lambda_{\min}(B)^2}$

and

$0 < \Delta t < \frac{2\alpha}{\Phi(\lambda_{\min})}$.

- $\Phi'(\xi) = 0$ for $\xi \in [\lambda_{\min}(B), \lambda_{\max}(B)]$. This means that

$\frac{\beta^2}{2\alpha} - \frac{\delta^2}{8\alpha \lambda_{\min}(B)^2} < \tau < \frac{\beta^2}{2\alpha} - \frac{\delta^2}{8\alpha \lambda_{\max}(B)^2}$.

This implies that $\Phi'(\lambda_{\min}(B)) < 0$ so $\max(\Phi(\xi))$ is reached at $\lambda_{\min}(B)$ or at $\lambda_{\max}(B)$ and the stability condition is

$0 < \Delta t < \frac{2\alpha}{\max(\Phi(\lambda_{\min}(B)), \Phi(\lambda_{\max}(B)))}$.

We point out that the symmetric part of matrix $A$ is dominant for small values of $\delta$ and that in this case the above stability result is to be compared with that of Proposition (2.1).

Particularly unconditional stability condition is obtained for $\tau \geq \frac{\beta^2}{2\alpha} + \frac{\delta^2}{8\alpha \lambda_{\min}(B)} \simeq \frac{\beta}{2}$, for unconditional preconditioners $B$ as those presented above.

4 Numerical Results

4.1 The problem and the numerical schemes

As stated in the introduction, we here aim at computing the steady state of the so-called 2D driven cavity problem in a rectangular domain $\Omega$. The steady state will be reached by a pseudo-temporal method, and for that purpose we consider the stream function-vorticity formulation
that we supplement with proper boundary conditions. We denote by $\Gamma_i \ i = 1, ..., 4$ the sides of the unit square $\Omega$ as follows: $\Gamma_1$ is the lower horizontal side, $\Gamma_3$ is the upper horizontal side, $\Gamma_2$ is the left vertical side, and $\Gamma_4$ is the right vertical side.

Figure 2: The lid driven cavity - Schematic localization of the mean vortex regions

We distinguish two different driven flows, according to the choice of the boundary conditions on the velocity. More precisely we have

- $g(x) = 1$ : Cavity A (lid driven cavity)
- $g(x) = (1 - (1 - 2x)^2)^2$ : Cavity B (regularized lid driven cavity)

We will also consider the steady linear part of this equation (the Stokes problem), whose the
solution will be chosen as the initial condition of (23)

\[-\frac{1}{Re} \Delta \omega = 0, \quad \text{in } \Omega \tag{26}\]
\[\omega |_{\partial \Omega} = \Delta \psi |_{\partial \Omega} \quad \text{on } \partial \Omega, \tag{27}\]
\[\Delta \psi = \omega, \quad \text{in } \Omega \tag{28}\]
\[\psi |_{\partial \Omega} = 0 \quad \text{on } \partial \Omega, \tag{29}\]

The RSS scheme is based on two different finite differences discretization of differential operators at the same grid points: a second order finite difference scheme will be used for preconditioning while the fourth order compact scheme is implemented for the effective approximation to the solution.

The boundary conditions on \( \omega \) are derived by the discretization of \( \Delta \psi \) on the boundaries. With the conditions on \( u \) and \( v \) we have

\[
\omega(x, 0, t) = \frac{\partial^2 \psi}{\partial y^2}(x, 0, t) \quad \text{on } \Gamma_1,
\]
\[
\omega(x, 1, t) = \frac{\partial^2 \psi}{\partial y^2}(x, 1, t) \quad \text{on } \Gamma_3,
\]
\[
\omega(0, y, t) = \frac{\partial^2 \psi}{\partial x^2}(0, y, t) \quad \text{on } \Gamma_2,
\]
\[
\omega(1, y, t) = \frac{\partial^2 \psi}{\partial x^2}(1, y, t) \quad \text{on } \Gamma_4.
\]

So, since \( \psi_{\partial \Omega} = 0 \) and \( u = \frac{\partial \psi}{\partial y}, \quad v = -\frac{\partial \psi}{\partial x} \), we obtain by using Taylor expansions

\[
\omega_{i,0} = \psi_{i,1} - 8\psi_{i,2} + \frac{2h^2}{i},
\]
\[
\omega_{i,N+1} = -\psi_{i,N-1} + 8\psi_{i,N} - 6h^g(ih),
\]
\[
\omega_{0,j} = \psi_{1,j} - 8\psi_{2,j} + \frac{2h^2}{j},
\]
\[
\omega_{N+1,j} = -\psi_{N-1,j} + 8\psi_{N,j}.
\]

Here \( g(x) \) denotes the boundary condition function for the horizontal velocity at the boundary \( \Gamma_3 \).

The boundary conditions on \( \psi \) are homogeneous Dirichlet BC. The operators are discretized by second order centered schemes on a uniform mesh composed by \( N \) points in each direction of the domain of step-size \( h = \frac{1}{N+1} \). The total number of unknowns is then \( 2N^2 \).

The boundary conditions on \( \omega \) are iteratively implemented according to the relations (30), making the finite differences scheme second order accurate. Using the following fourth order accurate extrapolation,
\[
\begin{align*}
\omega_{i,0} &= \frac{1}{h^2} \left( 8\psi_{i,1} - 3\psi_{i,2} + \frac{8}{9}\psi_{i,3} - \frac{1}{8}\psi_{i,4} \right), \\
\omega_{i,N+1} &= \frac{1}{h^2} \left( 8\psi_{i,N} - 3\psi_{i,N-1} + \frac{8}{9}\psi_{i,N-2} - \frac{1}{8}\psi_{i,N-3} \right) - \frac{25}{6h} g(ih), \\
\omega_{0,j} &= \frac{1}{h^2} \left( 8\psi_{1,j} - 3\psi_{2,j} + \frac{8}{9}\psi_{3,j} - \frac{1}{8}\psi_{4,j} \right), \\
\omega_{N+1,j} &= \frac{1}{h^2} \left( 8\psi_{N,j} - 3\psi_{N-1,j} + \frac{8}{9}\psi_{N-2,j} - \frac{1}{8}\psi_{N-3,j} \right),
\end{align*}
\] (31)

we complete the discretization. Now the implementation of the RSS scheme reads as

- Convection-Diffusion problem: knowing \( \psi^{(k)} \), compute \( \omega^{(k+1)} \) solution of

\[
\begin{align*}
\frac{\omega^{(k+1)} - \omega^{(k)}}{\Delta t} - \frac{1}{Re} \Delta \omega^{(k+1)} + \frac{\partial \psi^{(k)}}{\partial y} \frac{\partial \omega^{(k)}}{\partial x} - \frac{\partial \psi^{(k)}}{\partial x} \frac{\partial \omega^{(k)}}{\partial y} &= 0 \quad \text{in } \Omega = ]0,1[^2 \\
\omega^{(k+1)} &= \Delta \psi^{(k+1)} \quad \text{on } \partial \Omega
\end{align*}
\] (32)

- Poisson problem: knowing \( \omega^{(k+1)} \), compute \( \psi^{(k+1)} \) solution of

\[
\begin{align*}
\omega^{(k+1)} &= \Delta \psi^{(k+1)} \quad \text{in } \Omega = ]0,1[^2, \\
\psi^{(k+1)} &= 0 \quad \text{on } \partial \Omega.
\end{align*}
\] (33)

\[\text{Algorithm 2 : RRS Navier-Stokes}\]

4: \quad Compute \(\omega^{(k+1)}\) by solving \((32)\) with RSS \((7)\)
5: \quad Compute \(\psi^{n+1}\) as solution of the Poisson equation \((33)\)
6: \textbf{end for}

4.2 RSS Schemes for computing Steady States of the lid driven cavity

We give now numerical results on the square cavity \( \Omega = ]0,1[^2 \), we compare the numerical values of the steady state with those of the literature. Here \( g(x) = 1 \).

The steady state is computed for \( \|\frac{\partial \psi}{\partial t}\| < \varepsilon = 10^{-3} \). We report hereafter the vorticity and the stream function in figures 3, 4, 5 and 6 for \( Re = 100, Re = 400, Re = 1000, Re = 3200 \) respectively. They agree with those of the literature [3, 4, 12, 13]; the localization of the extrema of \( \omega \) and \( \psi \) are reported on table 2.
Figure 3: Steady solution of NSE (23) - $g \equiv 1 - \tau = 1 - N = 127 - Re = 100 - \Delta t = 0.001$

Figure 4: Solution of NSE (23) - $g \equiv 1 - \tau = 1 - N = 127 - Re = 400 - \Delta t = 0.001$

Now we illustrate the influence of the stabilization parameter $\tau$ on the convergence in time to the steady state. A large value of $\tau$ allows to take a large time step $\Delta t$ but slows down the convergence in time. We have plotted in figures (7) and (8) the evolution in time of $\|\frac{\partial \psi}{\partial t}\|$. We observe that, for $\tau = 1$ the RSS schemes (first and second order) behave similarly as the reference one (semi backward Euler’s); for $\tau = 100$, we see that RSS is slow downed while its extrapolated version has comparable dynamics to Euler’s.

We now give numerical results for the rectangular cavity. They are presented in figures (9), (10), (11) and (12) for $Re = 100$, $Re = 400$, $Re = 1000$, $Re = 3200$ respectively. They agree with those obtained by Goyon [13], see also the numerical values reported in Table 3.
Figure 5: Solution of NSE \((23)\) - \(g \equiv 1 - \tau = 1 - N = 127 - Re = 1000 - \Delta t = 0.0005\)

Figure 6: Solution of NSE \((23)\) - \(g \equiv 1 - \tau = 1 - N = 127 - Re = 3200 - \Delta t = 0.0005\)
\[ \text{Re} = 100 \]

Here the vorticity $\omega$ and the streamfunction $\psi$ at steady state for $Re = 3200$. The maximal values found for $\psi$ are, for the maximum 0.0196 located in $(x,y) = (0.4492, 0.6914)$ and the minimum is $-1.215$, located in $(x,y) = (0.5156, 1.15664)$.

4.3 On the role of $\tau$ and of the extrapolation to the convergence in time to the steady state

We now denote by $T_c$ the time at which the convergence to the steady state is reached, say $T_c = (k+1)\Delta t$ with $\| \psi^{(k+1)} - \psi^{(k)} \Delta t \| \leq \epsilon$. We put the symbol $\ast\ast\ast$ when the scheme is unstable and blows up numerically; 'NC' when it is not convergent after a given large time ($T=2000$) and finally 'Inc. Stab' when it is inconditionally stable.

We first consider the RRS scheme with the second order laplacian matrix as a preconditioner. We show for low Reynolds numbers, that a large value of $\tau$ allows to use large $\Delta t$ and that the slower convergence to the steady state can be corrected by using the Richardson extrapolation.

Of course, since the stabilization allows to take larger time steps, a important gain in CPU time can be obtained when computing a steady state. It can be estimated by considering the number of iteration in time $NT$: $\frac{T_c}{\Delta t}$ for RSS and $3 \frac{T_c}{\Delta t}$ for RSS with extrapolation. For example, taking $Re = 400$ and $n = 127$, we find $NT = 2501$ for $\tau = 1$ and $\Delta t = 0.014$ and for $\tau = 30$ and $\Delta t = 0.6$, we have $NT = 410$ (RSS) and $NT = 568$ (RSS with extrapolation) ; hence a factor 6.1 is reached for RSS and one of 4.4 for extrapolated RSS, see Table 5.
\[ \frac{\omega^{(k+1)} - \omega^{(k)}}{\Delta t} + \left( \frac{1}{Re} A_2 + \text{diag}(Dy\psi^{(k)})Dx - \text{diag}(Dx\psi^{(k)})Dy \right) (\omega^{(k+1)} - \omega^{(k)}) = -F(\psi^{(k)}, \omega^{(k)}) \] (34)

where \( A_2 \) is the second order laplacian matrix, \( \text{diag}(Dy\psi^{(k)}) \) (resp. \( \text{diag}(Dx\psi^{(k)}) \)) is the diagonal matrix with the discrete (second order accurate) approximation of \( \frac{\partial \psi^{(k)}}{\partial x} \) (resp. \( \frac{\partial \psi^{(k)}}{\partial y} \)) at grid points as entries; \( Dx \) (resp. \( Dy \)) denote the (second order accurate) first derivative matrix in \( x \) (resp. in \( y \)) on the cartesian grid. Finally \( -F(\psi^{(k)}, \omega^{(k)}) \) is the high order compact scheme discretisation of \( -\frac{1}{Re} \Delta \omega + \frac{\partial \phi}{\partial y} \frac{\partial \omega}{\partial x} - \frac{\partial \phi}{\partial x} \frac{\partial \omega}{\partial y} \).

As Shown on Table 6 and Table 7, NLRSS outperform RSS for the computation of Steady

States for higher Reynolds numbers, for \( Re = 1000 \) and \textit{a fortiori} for \( Re = 3200 \). It allows to use large time steps while RSS is unstable for such \( \Delta t \).

### 5 Concluding remarks

We have studied RRS-like scheme (and their implementations) and pointed out their advantages for the numerical solution of parabolic problems when using high order compact schemes in finite differences for the space discretization. In particular, the possibility of using fast solvers attached to a standard second order discretization, speeds up the resolution while bringing an enhanced stability. We also pointed out the role of the approximation of \( \tau B \) to \( A \) in the dynamics of the convergence to a steady state: a too strong stabilization slows down the convergence in time while enhancing the stability of the scheme, the application of Richardson extrapolation allows to recover a dynamics close to the one of the classical schemes. The robustness of the schemes is illustrated with the solution of 2D NSE equations. The RSS approach is very versatile and allows adaptations of a large number of techniques of numerical analysis of ODEs. Many developments remain to consider, such as applying factorization updatings on the preconditioners or deriving and applying multilevel general (or Block) RSS schemes for the solution of other large scale parabolic problems.
