Purpose: Human infections caused by invasive non-typhoidal Salmonella (iNTS) are highly prevalent worldwide. However, data for such infections in China are scarce. This study reports the epidemiology of iNTS in China.

Methods: iNTS isolates were recovered from blood and other clinical specimens collected during 2007–2016 across five provinces (Shanghai, Xinjiang, Fujian, Guangxi, and Chongqing) in China. Antimicrobial susceptibility was performed using the agar dilution method and molecular epidemiology was performed using standard microbiological techniques.

Results: A total of 178 iNTS isolates were recovered from approximately 9700 patient specimens during 2007–2016. The predominant serovars were Salmonella Enteritidis (57/178, 32%), Salmonella Choleraesuis (47/178, 26.4%), and Salmonella Typhimurium (24/178, 13.5%). Up to 50 isolates (28.1%) were from patients who were ≤1 year of age, while 28 (15.7%) were from patients who were ≥60 years. Among these isolates, high rates of resistance to nalidixic acid (114/178, 64%), sulfisoxazole (59%), ciprofloxacin (15.2%), and ceftoxime (8.4%) were found. Moreover, 53.4% (95/178) exhibited multidrug resistance, and 3.9% (7/178) showed co-resistance to third-generation cephalosporins and ciprofloxacin. Steadily increasing numbers of nalidixic acid, ceftoxime, and ciprofloxacin-resistant isolates, but decreasing numbers of multidrug resistance isolates were detected during the study period. Detection of quinolone genes in 114 nalidixic acid-resistant isolates showed that 58.3% (67/114) harbored plasmid-mediated quinolone resistance (PMQR) genes [aac(6’)-Ib-cr, qnrA, qnrB, qopAB, qepA, qnrS, and qnrD] and 98.2% (112/114) exhibited mutations in quinolone resistance determining regions [gyrA, parC, and parE]. Furthermore, we detected beta-lactamases genes in the ceftriaxone-resistant isolates. The most common were blaox-EM-1 (93.3%), followed by blaox-CTX-M-35 (40%), blaox-TEM-2 (33.3%), and blaox-oxa-1 (33.3%). Finally, a range of pulsed-field gel electrophoresis patterns were detected among the Salmonella Enteritidis and Salmonella Typhimurium isolates.

Conclusion: High rates of multidrug resistance and steady increasing ceftoxime and ciprofloxacin-resistant iNTS could pose a significant challenge for the effective treatment of salmonellosis in China.

Keywords: invasive non-typhoidal Salmonella, fluoroquinolones, multidrug resistant, beta-lactamases, pulsed field gel electrophoresis, China

Plain language summary
Infections caused by invasive non-typhoidal Salmonella (iNTS) bacteria occur when non-typhoidal Salmonella, which normally cause diarrhea, enter the bloodstream and spread through the body. iNTS infections have become a common cause of infection and death in children and elderly patients, accompanied with other diseases, in sub-Saharan Africa.
However, data for such infections is unknown outside of sub-Saharan Africa. In particular, related data for China, with a large population, is scarce. This study reports on the epidemiology of iNTS in China, in which 178 iNTS isolates were isolated and Salmonella Enteritidis, Salmonella Choleraesuis, and Salmonella Typhimurium were the main serovars. Over half (53.4%) of the isolates exhibited multidrug resistance and 3.9% showed co-resistant to third-generation cephalosporins and ciprofloxacin. Steadily increasing nalidixic acid, cefotaxime, and ciprofloxacin-resistance, but decreasing multidrug resistance, were detected during the study period. The occurrence and diversity of mutations in QRDR and the PMQR genes, conferring fluoroquinolone resistance, in our research were much higher than those reported for iNTS isolates in other regions. A high proportion of cefotaxime-resistant isolates exhibited at least two beta-lactamase genes, which is seldom reported in iNTS isolates. In conclusion, high rates of multidrug resistance and the steadily increasing cefotaxime- and ciprofloxacin-resistant iNTS could pose a significant challenge for the effective treatment of salmonellosis in China.

Introduction

Invasive bacterial infections caused by invasive non-typhoidal Salmonella (iNTS) are a significant public health threat worldwide. An estimated 3.4 million cases of infection and over 680,000 deaths occur annually globally.\(^1\)\(^2\) In developed countries, such as the United States, the incidence of iNTS is low, and NTS infections that spread through contaminated food result in a self-limiting diarrheal disease, with invasive disease being rarely recorded.\(^3\) However, in Africa, iNTS ranks as the primary cause of community-acquired invasive bacterial disease and is responsible for nearly 17% of bacterial bloodstream cases.\(^4\)\(^5\) Infections with iNTS in low-income areas often result in meningitis and septicemia, and these severe infections more frequently occur in immunocompromised hosts and children who are malnourished and are co-infected with malaria.\(^6\)\(^7\) China is a big country with a population of about 1.4 billion, and 70–80% of bacterial food poisoning are caused by Salmonella.\(^8\) Despite the severe infections caused by iNTS worldwide, little data is available on iNTS infections in China.

Antimicrobial agents are critical to treat patients with complex iNTS infections to reduce the mortality rate. The massive use of antimicrobials to treat patients has caused the resistance rate to increase and the widespread occurrence of iNTS isolates with multidrug resistance (MDR) against traditional antimicrobial agents in Asia and Africa, which often results in death, representing an important public health problem.\(^9\)\(^10\)\(^11\) The extended-spectrum cephalosporins and fluoroquinolones have become the first-line drugs to treat iNTS cases; however, this conversion has resulted in the emergence of iNTS isolates resistant to these drugs.\(^9\)

Therefore, we carried out a study to investigate iNTS infections in China from 2007 to 2016 to determine the molecular epidemiology and antimicrobial susceptibility characteristics of iNTS. The information provided will be useful to develop a comprehensive national surveillance program to help guide clinicians to choose the appropriate treatment for this disease.

Materials and methods

Ethics statement

Ethical approval for this study was provided by Shanghai Municipal Center for Disease Control and Prevention (Shanghai, China). This study was performed retrospectively, and individual patient identification was not accessed and informed consent was not required.

Sample collection and isolate identification

Approximately 9700 clinical samples, including blood, peritoneal fluid, joint fluid, bone fluid, cerebrospinal fluid (CSF), and aspirates were collected from patients presenting with fever at five Government General Hospitals and five Provincial Center for Disease Control and Prevention (CDC) laboratories in Shanghai, Xinjiang, Guangxi, Chongqing, and Fujian Provinces in China from January 2007 to December 2016. The samples were processed following standard blood culture procedures. Briefly, the clinical samples were inoculated into the bottles of aerobic blood culture and incubated in a BACTEC 9050 automated blood culture machine (Becton Dickinson, Franklin Lakes, NJ, USA) according to previously published methods.\(^12\) Commercial antisera (Statens Serum Institut, Copenhagen, Denmark) were used to detect the Salmonella serovars. Rainfall information was retrieved from [http://www.cma.gov.cn/using](http://www.cma.gov.cn/using) the combined rainfall data for the five provinces. To avoid confounding effects, patients with multiple positive blood cultures for the same NTS serovar and antimicrobial susceptibility profile were considered as a single case. Cases in which the responsible microbial agent could not be identified were excluded from the analysis of categorical variables to prevent statistical bias.
Antimicrobial susceptibility testing
Antimicrobial susceptibility to 12 drugs was performed for the iNTS isolates, using an agar dilution method according to the guidelines of Clinical and Laboratory Standards Institute (CLSI) standards. The tested antimicrobial agents comprised: Tetracycline (TET), polymyxin B (PB), imipenem (IPM), chloramphenicol (C), ciprofloxacin (CIP), ofloxacin (OFX), nalidixic acid (NA), sulfisoxazole (SUL), streptomycin (STR), cefepime (CFP) (fourth-generation cephalosporin), cefotaxime (CTX) (third-generation cephalosporin), and ampicillin (AMP). For ciprofloxacin, “ciprofloxacin susceptibility” was used to indicate a minimum inhibitory concentration (MIC) value ≤0.06 mg/L; the term “resistant to ciprofloxacin susceptibility” was reserved for MIC values >0.06 mg/L and <1 mg/L; and the “resistance breakpoint” meant MIC values ≥1 mg/L. Escherichia coli isolates ATCC 25922 and ATCC 35218 served as quality control isolates. The results were interpreted on the basis of CLSI guidelines.

Molecular analysis of quinolone and cephalosporin resistance
The analysis of quinolone resistance was conducted on 114 NA resistant iNTS isolates by amplification and sequencing of the quinolone resistance determining regions (QRDRs) of the DNA gyrase (gyrA and gyrB) and DNA topoisomerase IV (parC and parE) genes, and screening for the presence of the plasmid-mediated quinolone resistance (PMQR) genes, according to methods detailed in a previous study. PCR screening and sequencing were conducted on 15 iNTS isolates that were resistant to cefotaxime (MIC ≥4 mg/L) to confirm the presence of beta-lactamase genes blaTEM, blaSHV, blaOXA, blaCMY, and blaCTX-M using standard methods. The forward and reverse primers for the beta-lactamase genes are shown in Table S1. The PCR products were sent to Sangon Biotech Co., Ltd. (Shanghai, China) for sequencing. Sequence data were then analyzed using DNASTar (DNASTar Inc., Madison, WI, USA) and the sequences were aligned using GenBank online BLAST software (http://www.ncbi.nlm.nih.gov/BLAST/).

Pulse field gel electrophoresis
Pulsed-field gel electrophoresis (PFGE) was performed for S. Typhimurium and S. Enteritidis isolates using the restriction enzyme XbaI (Takara, Dalian, China) according to the PulseNet protocol, as described previously. Salmonella enterica serotype Braenderup H9812 served as standard control isolate. The PFGE results were analyzed using BioNumerics version 6.5 software (Applied Maths, Kortrijk, Belgium).

Statistical analysis
Comparison of frequencies was calculated using the Chi-squared test in SAS 9.2 (SAS Institute, Cary, NC, USA). A P-value <0.05 was considered to indicate statistical significance.

Results
Serovars and distribution of age
One hundred and seventy eight iNTS isolates were detected during the study period: 86 isolates from Shanghai, 33 isolates from Chongqing, 10 isolates from Fujian, 42 isolates from Guangxi, and 7 isolates in Xinjiang provinces were recovered from approximate 4900, 1400, 700, 2100 and 600 clinical samples, respectively (Table S2). One hundred and forty six (82%) were collected from blood, five (2.8%) from cerebrospinal fluid, and twenty-seven (15.2%) from joint fluid, peritoneal fluid, bone, and aspirates. Among the isolates, 57 (32%) were identified as S. Enteritidis, 47 (26.4%) as S. Choleraesuis, and 24 (13.5%) as S. Typhimurium, which were the top three serovars, followed by five (2.8%) S. London, four (2.2%) S. Derby, four (2.2%) S. Virehows, four (2.2%) S. Livingstone, four (2.2%) S. Give, three (1.7%) S. Weltevreden, two (1.1%) S. Indiana, two (1.1%) S. Mleagadris, two (1.1%) S. Thompson (1.1%), and seventeen other serovars (Table 1). The aggregate age distribution of infections is displayed in Table S3. Up to 28.1% (50/178, p<0.01) of the infections were in patients ≤1 year of age, while 15.7% (28/178, p<0.01) were in patients ≥60 years old. The male-to-female ratio was approximately 1.43 for iNTS infections. The numbers of iNTS isolations fluctuated over the months, and a seasonal trend was observed, in which an increase in iNTS infections appeared to occur during seasons of concentrated rainfall, mainly between May and October (Figure 1).

Salmonella meningitis
Besides causing bloodstream infections, iNTS are also a cause of life-threatening meningitis in China. From 2007 to 2016, there were five cases of culture-confirmed iNTS meningitis China. The serovars responsible for the iNTS meningitis cases included S. Enteritidis (two), S. Typhimurium (one), S. Derby (one), and S. Indiana (one).
Table 1: Antimicrobial susceptibility among 178 invasive non-typhoidal Salmonella isolates from humans in China, during 2007 to 2016

**Notes:** *All isolates were susceptible to Imipenem. The resistance breakpoint for ciprofloxacin is ≥1 mg/L and for cefotaxime is ≥4 mg/L.

**Abbreviations:** CIP, ciprofloxacin; CTX, cefotaxime; CFP, cefepime; PB, polymyxin B; OFX, oﬂoxacin; AMP, ampicillin; SUL, Sulﬁsaxazole; C, chloramphenicol; TET, tetracycline; NA, nalidixic acid; STR, streptomycin; MDR, multidrug resistant.
The first case of *Salmonella* meningitis occurred in 2012. All meningitis occurred in children and three cases (60%) involved infants <1 year of age.

**Antimicrobial resistance**

The results of antimicrobial resistance for the tested antibiotics for the 178 iNTS isolates are displayed in Table 1. Among these isolates, 114 (64%) were resistant to nalidixic acid, 105 (59%) to sulfisoxazole, 81 (45.5%) to streptomycin, 71 (39.9%) to tetracycline, 52 (29.2%) to chloramphenicol, 27 (15.2%) to ciprofloxacin, 27 (15.2%) to ofloxacin, 18 (10.1%) to ampicillin, 15 (8.4%) to cefotaxime, 3 (1.7%) to cefepime, and 2 (1.1%) to polymyxin B. Forty-two (61.8%) isolates showed decreased ciprofloxacin susceptibility. Overall, 95 (54.3%) serovars were MDR (MDR being defined as resistant to three or more antimicrobial classes). Furthermore, we detected seven (3.9%) isolates that displayed the ACSSuT pattern (ACSSuT is defined as resistant to tetracycline, sulfamethoxazole, streptomycin, chloramphenicol, and ampicillin) and seven (3.9%) isolates showed co-resistance to cefotaxime and ciprofloxacin. There was a gradual decline in the percentage of MDR isolates (from 80% in 2007 to 30.6% in 2016; *P*<0.05) during the study period, as well as a parallel increase in nalidixic acid-resistant (NAR) (from 40% in 2007 to 75% in 2016), cefotaxime resistance (from 0% in 2007 to 13.9% in 2016), ciprofloxacin resistance (from 0% in 2007 to 19.4% in 2016), and ACSSuT pattern isolates (from 0% in 2007 to 11.1% in 2016). All iNTS isolates exhibited susceptibility to imipenem (Table 2 and Figure 2).

Among the iNTS serovars, *S. Choleraesuis*, *S. Typhimurium*, and *S. Enteritidis* comprised high proportions of MDR isolates: 38/47 [80.9%], 17/24 [70.8%], and 24/57 [43.1%], respectively. The proportions of MDR isolates of *S. Choleraesuis* and *S. Typhimurium* were

*Abbreviations: susceptible*, susceptible to all tested antibiotics; MDR, resistance to three or more antimicrobial classes; CIP, ciprofloxacin resistant; NAR, nalidixic acid resistant; CFX, cefotaxime resistant; CFP, cefepime resistant; ACSSuT, resistance to tetracycline, sulfamethoxazole, streptomycin, chloramphenicol and ampicillin.
significantly higher than that of S. Enteritidis (p<0.05). Fifteen (31.9%) S. Choleraesuis and four (16.7%) S. Typhimurium isolates exhibited resistance to ciprofloxacin. In addition, the uncommon serovars S. Livingstone, S. Meleagridis, S. Thompson, and S. Indiana showed resistance to cefotaxime, ciprofloxacin, and the ACSSuT pattern (Tables 1 and 3).

Molecular analysis of quinolone resistance
Detection of PMQR genes in the 114 NAR iNTS isolates showed that aac(6′)-Ib-cr (33.3%, 38/114) was the most common gene, 20 (17.5%) isolates harbored qnrA, 15 (13.2%) harbored qnrB, 8 (7%) harbored qepA, 5 (4.4%) harbored qnrS, and 4 (3.5%) harbored qnrD. Sixty-seven (58.3%) NAR isolates were detected to harbor at least one PMQR gene. The coexistence of two or more PMQR genes in a single isolate was observed in 32 isolates.

Correlations among the ciprofloxacin MIC, NAR, and genomic mutations in the QRDR of 114 NAR isolates, are displayed in Table 4. All 47 NAR isolates with susceptibility to ciprofloxacin possessed a single point mutation in the gyrA gene (either at Ser83 or Asp87) only. Of the 40 NAR isolates with decreased ciprofloxacin susceptibility, 17 had a single point mutation in the gyrA or parC genes only, and 23 possessed a single gyrA mutation and at least one parC mutation. While for the 21 isolates with ciprofloxacin resistance (MIC 1–2 mg/L), 19 (90.5%) showed one mutation in gyrA and at least one parC mutation. All isolates with high ciprofloxacin MIC (≥4 mg/L) exhibited five mutations, double point mutations in the both genes gyrA and parC, and a single parE mutation (at positions 538 or 530 or 458). Overall, all the isolates that carried PMQR genes possessed mutations in the QRDRs.

Detection of beta-lactamases
Of the 15 isolates resistant to ceftriaxone, 14 (93.3%) were found to harbor blaTEM-1 genes. Six (40%) isolates were positive for blaCTX-M-55, blaCMY-2, and blaOXA-1 genes were observed in five isolates (33.3%). One (6.7%) isolate was positive for the blaSHV-2 gene. All isolates exhibited the detected beta-lactamase resistance genes and 12 (80%) isolates harbored at least two beta-lactamase resistance genes (Table 3).

Pulsed-field gel electrophoresis
Fifty-seven S. Enteritidis and 24 S. Typhimurium isolates were subjected to PFGE genotyping. Figure 3 shows that 30 PFGE patterns (non-clonal) were observed from the 57 S. Enteritidis isolates, and these could be divided into six clusters at 80% similarity (A to F). Cluster E was the biggest cluster and included 51 (89.5%) isolates. Among the 24 S. Typhimurium isolates (Figure 4), 21 PFGE patterns (non-clonal) were identified, and these could be divided into nine clusters (A–I) at 80% similarity.

Discussion
Infections caused by iNTS are a significant public health threat worldwide. Our study revealed the 178 iNTS isolates were identified from a number of specimen types, which was similar to earlier reports. A high percentage (30.3% (54/178) and 14.6% (26/178), respectively of iNTS infections were in patients ≤1 or ≥60 years of age. The

Notes: *Indicates units of related antibiotics is mg/L. Gray shading indicates the isolate with ACSSuT pattern without resistant to cefotaxime. None indicates that the relevant genes were not tested. - indicates that the relevant genes were tested but not detected.

Abbreviation: CSF, cerebrospinal fluid; d, day; m, month; y, year; SH, Shanghai; GX, Guangxi; CQ, Chongqing; FJ, Fujian.
isoalterations in the QRDRs of gyrB were not found in any of the isolates tested. The a indicates that isolates exhibit at least two mutations in the QRDRs. The b indicates that isolates exhibit one mutation in the QRDRs. The c indicates that isolates exhibit both mutations in the QRDRs and PMQR gene.

Our study found that S. Enteritidis and S. Typhimurium were the main serovars, causing approximately 45.5% of iNTS infections, which was similar to previous studies. Furthermore, one of the most significant discoveries in our study was that S. Choleræsuis was an important serovar, representing a high proportion of the isolates identified. We believe it may be explained as follows: Pork production in China ranked first in the world and pork is very popular in the Chinese diet. S. Choleræsuis is particularly prone to infecting pork meat. This is consistent with reports from Taiwan and Thailand, where S. Choleræsuis is an important invasive pathogen that causes severe infections. Although there is a lack of data pertaining to the prevalence of invasive NTS around the world, it would appear that there are regional discrepancies in the circulation of Salmonella serovars.

Invasive Salmonella diseases are related to high case fatality rates (>20%) and prompt antimicrobial therapy is critical for this complex disease. The present study identified a high resistance rate to streptomycin, sulfonamides, and nalidixic acid, which were significantly higher than those in North America, where the resistance rates of iNTS isolates to streptomycin, sulfonamides, and nalidixic acid were 8.8, 8.4, and 11.3% from 2003–2013. We identified a high proportion (53.4%) of the iNTS isolates displayed MDR; in particular, 80.9% of S. Choleræsuis and 70.8% of S. Typhimurium isolates exhibited MDR. These rates were higher compared with those in previous studies from United States and Kenya, in which the MDR rates were 9.0% and 4.0%, respectively. Furthermore, we found that a high proportion (53.4%) of the iNTS isolates developed MDR. These rates were higher compared with those in previous studies from United States and Kenya, in which the MDR rates were 9.0% and 4.0%, respectively. High levels of drug resistance and MDR constitute a significant public health threat and are strongly associated with higher morbidity and mortality.

A gradual decline in the percentage of iNTS MDR isolates was detected during the study period. This was accompanied by a gradual increase in the number of NAR, ciprofloxacin, and cefotaxime-resistant isolates. This phenomenon is most probably explained by the reduction in the prescription of traditional antibiotics and an increased dependence on ciprofloxacin and cefotaxime as the first-line drugs to treat clinical iNTS infections in China. This is similar to reports from...
Figure 3 Dendrogram of pulsed field gel electrophoresis (PFGE) patterns of 57 Salmonella Enteritidis isolates recovered from these five provinces. Six clusters (A–F) were identified.
Kenya and United States, where resistance rates toward ceftriaxone (third-generation cephalosporin) increased during the study period.\textsuperscript{6,19,27} Indeed, in China the rates of resistance of iNTS isolates to ciprofloxacin, cefotaxime, and ACSSuT pattern were 15.2%, 8.4%, and 3.9%, respectively. In particular, the resistant rate emerged early in the study from 0, rising up to 19.4% for ciprofloxacin and 13.9% for cefotaxime in 2016, which is of great concern. These resistant rates were much higher than those previously reported in the United States and Africa, where such drug resistance has been identified, but remains uncommon.\textsuperscript{19,28–30} More importantly, co-resistance to ciprofloxacin, cefotaxime, ACSSuT pattern, and polymyxin B was identified in the iNTS isolates in the present study. These resistant phenotype isolates were detected among the uncommon \textit{Salmonella} serovars, and most were found in infants that were ≤1 year of age, which makes the infections more life-threatening, reminding us that we should pay more concerns to these uncommon serovars.\textsuperscript{19,22,31} In our opinion, the emergence and high level resistance to ciprofloxacin, cefotaxime, and the ACSSuT pattern in iNTS are deeply worrying, because these drugs are considered critically important according to WHO criteria in human medicine and the ACSSuT pattern is difficult to treat,\textsuperscript{31,32} which greatly limits clinically usable treatment options and leaving only more expensive drugs, such as carbapenems and tigecycline, as possible treatment options.

The main mechanisms of quinolone resistance in \textit{Salmonella} are mediated by QRDR and PMQR genes.\textsuperscript{33} Most isolates (98.2%; 112/114) contained mutations in the QRDR and 58.8% (67/114) of the isolates carried PMQR genes. The occurrence and diversity of mutations in the QRDR and PMQR genes in the present study were much higher than those reported for iNTS in other Asian and African regions.\textsuperscript{13,22,24,34} Furthermore, in the present figure, the PFGE patterns of 24 \textit{Salmonella} Typhimurium isolates recovered from these five provinces are shown. Nine clusters (A–I) were identified.
study, multipoint mutations in QRDR and/or two or more in PMQR genes co-existing in a single isolate were frequently detected, whereas this has seldom been observed among iNTS isolates from other regions. A single point mutation in QRDR will confer resistance to nalidixic acid and multipoint mutations in QRDR confer a high MIC value for ciprofloxacin, while mutations in the PMQR genes confer a modest decrease in susceptibility to ciprofloxacin. This might explain why these isolates have a high nalidixic acid-resistance rate and a high proportion of them had high a MIC value for ciprofloxacin. In addition, among the substitutions Asp530→Asn, Ala538→Thr, and Ser458→Pro, found in the QRDR of parE in our study, Ser458→Pro has been observed in a few parE sequences from S. Schwarzengrund that were related with ciprofloxacin resistance. Meanwhile, the substitutions Asp530→Asn and Ala538→Thr have not been previously reported, and were observed in the NAR and ciprofloxacin (MIC >4 mg/L) isolates; therefore, they are probably associated with fluoroquinolone resistance in these isolates. The aac(6’)-Ib-cr gene was identified commonly in 33.3% (38/114) of isolates. Isolates carrying these PMQR genes will pose a potential threat because their resistance to ciprofloxacin will increase with the increase in chromosomal mutant selection.

Similar to previous reports, the cefotaxime-resistant isolates in the present study contained the relevant beta-lactamasess [TEM-1, CTX-M-55, OXA-1, SHV-2, and CMY-2] and high proportions (80%) of cefotaxime-resistant isolates were observed to harbor at least two bla genes, which may be interpreted as a high level of resistance of cefotaxime, which has rarely been documented in iNTS before.

Interestingly, there was no correlation between the antimicrobial resistance and particular clonal genotypes of S. Enteritidis and S. Typhimurium. The PFGE analysis showed that the isolates of S. Enteritidis from different regions of the PFGE profiles (X1, X2, X3, X4, and X5) shared a distinctly high genetic similarity (>92%). This indicated the potential for cross-infections and horizontal transmission. The results of the PFGE study reveal that genotype diversity exists in S. Typhimurium in China, which suggested that there are multiple, independent clones in different regions of the world.

Conclusion
This study revealed that S. Enteritidis, S. Choleraesuis, and S. Typhimurium mainly cause iNTS infections; however, other serovars are also important. It is also a major threat to infant and elderly patients. An important alarm was the emergence and high level of resistance to cefotaxime, ciprofloxacin, and the ACSSuT pattern in iNTS isolates, which will pose new challenges for clinicians. To better manage and prevent the spread of antimicrobial resistance, especially in China with its large population, emphasis should be placed on the need for comprehensive surveillance to acquire accurate epidemiological information to help treat iNTS infections.
