Studies have shown that bone marrow-derived cells play an important role in tumor recurrence after chemotherapy and radiotherapy. In this study, we examined the relationship between the accumulation of Gr-1+CD11b+ cells and tumor recurrence after irradiation in tumor-bearing mice. By transplanting bone marrow cells into whole body-irradiated mice depleted of bone marrow, we assessed the role of Gr-1+CD11b+ cells in lung carcinoma models after local irradiation (LI). 20 Gy local irradiation could recruit CD11b+CXCR4+ cells into the irradiated tissues, and the recruited CD11b+CXCR4+ cells could promote tumor recurrence. Further 6 Gy whole body irradiation (WBI6Gy) could decrease tumor recurrence by inhibiting the accumulation of Gr-1+CD11b+ cells and then suppressing tumor vasculogenesis and angiogenesis. Our results suggest that the accumulation of CD11b+Gr-1+ cells promote tumor re-growth after local irradiation by enhancing tumor neovascularization, and low dose of whole body irradiation or irradiation of enlarged spleen may provide a new alternative for anti-angiogenesis therapies.

Epidemiological, clinical and experimental studies have demonstrated a link between chronic inflammation and cancer progression1–3. Tumor angiogenesis is a crucial step in tumor development since tumors have to establish a blood supply to grow and metastasize4,5. Mounting evidence has shown that tumor-infiltrating myeloid cells, such as tumor-associated macrophages (TAMs)6–8, Tie-2 expressing monocytes (TEMs)9,10, endothelial progenitor cells (EPCs)11–13, play a pivotal role in tumor angiogenesis. In some tumors, upon recruitment to tumors, these cells contribute to the revascularization by incorporating into the pre-existing vessels or secreting pro-angiogenic factors14. The two processes are referred to as vasculogenesis and angiogenesis, but their exact mechanisms have been poorly understood8. Gr-1+CD11b+ myeloid cells of myeloid macrophage/DC (dendritic cells) lineage are significantly increased in spleen and bone marrow of tumor-bearing animals and elevated Gr-1+CD11b+ myeloid cells are associated with impaired immune reactivity and tumor progression15–17. Tumor tissues tend to express high levels of chemotactic factors such as CXCL12, CCL2, and stem cell factor (SCF), which recruit Gr-1+CD11b+ myeloid cells to the tumors15,18,19. The recruited cells are then involved in the tumor vasculature by secreting MMP9 (Matrix Metalloproteinases 9) or differentiating into endothelium-like cells or other vascular cells20–22. It has been well documented that Gr-1+CD11b+ myeloid cells play a crucial role in the regulation of tumor neo-vasculature and tumor recurrence23. TAMs and TEMs have been reported to play a key role in the tumor recurrence after local irradiation (LI)24–26, but the underlying mechanism by which Gr-1+CD11b+ myeloid cells promote tumor recurrence after local irradiation (LI) remain unclear. In this study, we examined the roles of various Gr-1+CD11b+ myeloid cells in the post-LI re-growth in a lung tumor model.

Results
Accumulation of Gr-1+CD11b+ myeloid cells with the progression of Lewis lung carcinoma in tumor-bearing mice. The presence of Gr-1+CD11b+ cells was flow cytometrically evaluated in the bone marrow, spleen, and peripheral blood (Fig. 1A–C). First, we examined the Gr-1+CD11b+ cells in the bone marrow (Fig. 1A). It was found that two weeks after tumor inoculation, over 40% of the bone marrow cells expressed Gr-1+CD11b+ makers in LCC tumor-bearing mice, but only 21% of the bone marrow cells did so in normal mice.
The proportion of Gr-1<sup>+</sup>CD11b<sup>+</sup> cells was also significantly increased to over 15% in spleen and 20% in the peripheral blood in tumor-bearing mice, against a ratio of less than 5% in normal mice (Fig. 1B and C). More importantly, the weight of the spleen of tumor-bearing mice were 7 times more than that of the control mice 35 days after tumor inoculation (Fig. 1D and E). The inflammatory cells in the lung also increased with the accumulation of Gr-1<sup>+</sup>CD11b<sup>+</sup> myeloid cells (Fig. 1F). These findings suggest that tumor progression affects the environment of the host, as manifested by the accumulation of Gr-1<sup>+</sup>CD11b<sup>+</sup> cells (Fig. 1E and F).

Figure 1 | Accumulation of Gr-1<sup>+</sup>CD11b<sup>+</sup> cells in LCC tumor-bearing mice. Flow cytometry analysis revealed that the proportion of Gr-1<sup>+</sup>CD11b<sup>+</sup> cells in the bone marrow (A) peripheral blood (B) and spleen (C) of tumor-bearing mice were increased with tumor progression. Increase in spleen weight followed the same pattern (D&E). HE staining showed that the inflammatory cells in the lung also increased with the accumulation of Gr-1<sup>+</sup>CD11b<sup>+</sup>myeloid cells (F). Scale bar, 50 μm. n = 10 mice for each group. All the experiments were repeated three times.

**Egress of CD11b<sup>+</sup> myeloid cells to the peripheral blood and the recruitment of CD11b<sup>+</sup> CXCR4<sup>+</sup> myeloid cells to the tumor induced by local irradiation.** In order to know whether local irradiation could induce the migration of Gr<sup>+</sup>CD11b<sup>+</sup> cells into the tumors, *in vivo* imaging system was used to monitor the local infiltration of mononuclear cells from the bone marrow and spleen of tumor-bearing mice. The imaging showed that DIL-stained cells could infiltrate into the 20 Gy-irradiated tumors but not into the non-irradiated tumors (Fig. 2A and B). Some of the infiltrating DIL-stained cells expressed CD11b marker (Fig. 2A). Flow cytometry showed that 20 Gy LI could significantly promote the migration of CD11b<sup>+</sup>Gr-1<sup>+</sup> cells into the peripheral blood one week after irradiation as compared with LLC-bearing mice without irradiation (Fig. 2C) (44.73% vs 26.53%, P < 0.001). The CD11b<sup>+</sup>Gr-1<sup>+</sup> cells were also recruited to the irradiated tumor tissues, accounting for 9% of the total irradiated tumor cells against a less than 5% ratio in their non-irradiated counterparts (Fig. 2D). HE staining showed the area...
of tumor necrosis was significantly larger in 20 Gy LI-irradiated tumors (Fig. 3A and B) and the number of recruited CD11b+ cells adjacent to the necrotic tissues was also increased in LLC mice (Fig. 3A and C) 1 week after 20 Gy local irradiation. These results indicated that irradiation altered the microenvironment of the tumor and thereby recruited Gr-1+CD11b+ cells into the tumor tissues.

20 Gy irradiated tumors were immunofluorescently examined for the co-expression of CD11b+CXCR4+ cells and results showed that number of cells expressing both CD11b+ and CXCR4+ were increased in the tumor tissues 7 days after irradiation (Fig. 4). Then AMD3100 was used to block the interaction between CXCR4 and SDF-1 to further confirm the role of CXCR4 in the recruitment of Gr-1+CD11b+ cells into the irradiated tumors34. Tumor-bearing mice were given AMD3100 two days before irradiation and the treatment lasted for 9 days. The infiltration of CD11b+CXCR4 cells was reduced upon AMD3100 treatment (Fig. 4B). It was found that AMD3100 treatment abolished the effect of LI on the recruitment of CD11b+ cells into the tumors, confirming the involvement of the CXCR4-expressing cells in the recruitment. Significantly, the infiltration of CD11b+CXCR4+ cells into the irradiated tumors was also decreased by WBI6Gy, which destroyed the bone marrow and depleted leukocytes temporarily (for 1.5–2 weeks) from the blood circulation (Fig. 4A and B). The finding suggested that WBI6Gy could effectively inhibit the recruitment of Gr-1+CD11b+ cells to the irradiated tumors. Transplantation of bone marrow from tumor-bearing mice into the WBI mice could restore the recruitment of Gr-1+CD11b+ cells in the WBI mice. Taken together, the above findings suggested that LI could increase the size of necrotic areas and the infiltration of CD11b+CXCR4+ cells into the microenvironment of the tumors, and SDF-1α-CXCR4 axis plays an important part in the recruitment of CD11b+ cells. Consistent with our results, other studies have shown that recurrent tumors following irradiation or tumors growing in an irradiated normal tissue were more hypoxic25,38 and therefore had elevated HIF-1 levels, which could induce the expression of SDF-1α and impact the SDF-1α-CXCR4 axis.

Delay of post-irradiation tumor recurrence by whole body irradiation via decreasing the accumulation of Gr-1+CD11b+

---

**Figure 2** Recruitment of mononuclear cells from the bone marrow of tumor-bearing mice to the irradiated tumors. DIL-stained mononuclear cells were recruited to the irradiated tumor (A), as shown by in vivo bioluminescent imaging (BLI) (B). The experiment was repeated three times. LI20Gy induced Gr-1+CD11b+ cell migration into the peripheral blood (C) and the irradiated tumor tissues (D). Mice in A were drawn by T.L. n = 10 mice for each group.

**Figure 3** Recruitment of the CD11b+ mononuclear cells to tumor necrotic tissues by local irradiation. HE staining showed a marked increase in necrotic regions (N) (A&B) 1 week after 20 Gy local irradiation. Immunohistochemical staining demonstrated that he recruitment of CD11b+ cells in Lewis lung carcinomas was also enhanced (A&C). ★★: P < 0.01. n = 10 mice for each group. All the experiments were repeated three times.
cells. In view of the fact that WBI significantly decreased the accumulation of Gr-1+CD11b+ cells, especially in the spleen, we further examined the effect of WBI on tumor growth. Tumor-bearing mice were treated with a sub-lethal dose of 6 Gy WBI and then the efficacy of the same radiation dose (20 Gy) administered either locally to tumors alone (LI20Gy) or LI14Gy in combination with 6 Gy WBI was compared. The growth of LCC tumors in C57BL/6 mice was initially arrested in both groups, while the tumor started to re-grow about 8 days later (Fig. 5A). It was noteworthy that the tumor growth was significantly delayed (12 days) in the mice treated with both LI and WBI as compared to LI alone (Fig. 5B). Moreover, WBI did not change the weight, appearance, or behavior of the mice (data not shown).

We then examined if post-irradiation tumor recurrence was correlated with accumulation of Gr-1+CD11b+ cells in the spleen (Fig. 5C). LI reduced the spleen weight, but WBI6Gy decreased the spleen weight more significantly (Fig. 5D), although the proportions of CD11b+Gr-1+ cells didn’t experience significant change (Fig. 5E). More importantly, flow cytometry exhibited that the percentage of Gr-1+CD11b+ cells in the peripheral blood and irradiated tumor tissues were also reduced significantly (Fig. 5F and G).

These results suggested that Gr-1+CD11b+ cells in the spleen might play an important role in the post-irradiation recurrence. One day after WBI6Gy, the irradiated mice were reconstituted with bone marrow cells from LLC-bearing mice without irradiation. BM reconstitution one day after LI plus WBI resumed the accumulation of CD11b+Gr-1+ cells in the spleen and infiltration of CD11b+Gr-1+ cells into the irradiated tissues, and thereby accelerated the tumor growth. We were led to conclude that WBI can significantly decrease the accumulation of CD11b+Gr-1+ cells in the spleen, reduce the infiltration of Gr1+CD11b+ cells in the tumor, and finally delay the tumor re-growth after irradiation.

Elimination of CD11b+ myelomonocytic cells-derived neovascu-

lature by WB16Gy. MVD in the harvested tumors of different groups was examined. LI14Gy plus WB16Gy significantly decreased MVD counts (P < 0.05) in the Lewis-lung carcinoma models as compared with LI20Gy alone (Fig. 6E). Moreover, bone marrow transplantation (with the proportion of CD11b+Gr-1+ cells from LLC-bearing mice being over 50%) one day after WBI6Gy abrogated the decrease and restored the CD31-expressing neo-vasculature (Fig. 6E). Monocytes/macrophages have been known to promote tumor neo-vasculature by direct incorporation into tumor endothelia or by paracrine secretion of pro-angiogenesis factors such as MMP-9, iNOS. One week after LI20Gy alone, frozen tumor sections were examined for co-expression of CD11b with CD31, α-SMA, MMP-9 and iNOS. Histological examination showed that the proportions of vessels co-expressing CD11b+CD31+ or CD11b+α-SMA+ to total CD31- or α-SMA-expressing vessels were 14.31% ± 2.43% and 12.50% ± 4.12% (Fig. 6A and C). On the other hand, the proportions of cells co-expressing CD11b+MMP-9+ or CD11b+iNOS+ to MMP-9- or iNOS-expressing cells were 65.44% ± 11.18% and 93.50% ± 12.41% (Fig. 6B and D).

These findings showed that pro-angiogenesis factors may play a more important role in neovasculature and irradiated tumors were able to recruit CD11b+ cells, which were involved in neovasculature more through an angiogeneic way than vasculogenenic way.

Role of iNOS in CD11b+ myelomonocytic cells-derived neo-

vasculature. iNOS expression in irradiated tumor tissues were then examined. IHC confirmed that LI20Gy increased the iNOS expression in the irradiated tumors while WB16Gy abrogated the increase of iNOS expression (Fig. 7A and B). However, bone marrow transplantation one day after WB16Gy could restore the expression of iNOS in locally-irradiated tumor tissues. Then, tumor tissues were flow cytometrically separated into tumor cells and stromal cells. Moreover, the NO immunofluorescence density (DAF-FM DA probe) were found to be significantly higher in the stromal tissues than in the tumor tissues (P < 0.05) (Fig. 7C–G). These data suggested that after irradiation iNOS from stromal cells was the major pool for NO and the infiltrating CD11b+ cells highly expressing iNOS had the potential to mediate tumor recurrence by enhancing tumor neovascularization after local irradiation.
Tumor vasculature is derived from sprouting of local vessels (angiogenesis) and bone marrow (BM)-derived circulating cells (vasculogenesis)\(^1\). Owing to the tumor-bed effect\(^3\),\(^7,\) tumor angiogenesis is abrogated due to the destruction of the pre-existing blood vessels after irradiation. Several studies have demonstrated that CD11b\(^+\) bone marrow-derived cells, such as TAMs and TEMs, play a crucial role in promoting tumor recurrence after irradiation by promoting vasculogenesis rather than angiogenesis\(^2\),\(^4\). TEMs, TAMs and MDSCs are all subpopulations of the total tumor infiltrating CD11b\(^+\) myeloid cells, and they could be distinguished from each other by their specific surface marker profile\(^4\). Therefore, Gr-1\(^+\)+CD11b\(^+\) myeloid cells, which were also of bone marrow origin, were believed to promote tumor neovasculature after irradiation\(^2\),\(^3\),\(^4\) but the detailed mechanisms were not fully understood.

CD11b\(^+\)+Gr-1\(^+\) myeloid cells can expand systemically in bone marrow, spleen and peripheral blood\(^2\),\(^3\),\(^4\). In this study, by using the Lewis lung carcinoma model, we demonstrated that accumulation of Gr-1\(^+\)+CD11b\(^+\) cells in tumor-bearing mice, especially in spleen, were associated with the progression of tumors. More importantly, we also revealed that Gr-1\(^+\)+CD11b\(^+\) cells could promote tumor recurrence by increasing MVD of irradiated LLC. An array of chemokines, growth factors, and adhesion molecules are required to work in concert with bone marrow cells to be mobilized to the peripheral bloods and recruited to tumor tissues. In particular, CXCR4 plays an important part in the recruitment of inflammatory...
cells to the irradiated tumor tissues. SDF-1/CXCR4 axis is also implicated in the recruitment of hematopoietic stem cells and progenitor cells, supporting our observation that Gr-1+CD11b+ cells had differentiation potential and were progenitor-like EPCs. Our data also showed that infiltration of Gr-1+CD11b+ cells into the irradiated tumor tissues was significantly reduced by using the CXCR4 antagonist AMD3100 and 6 Gy whole body irradiation. More importantly, 6 Gy whole body irradiation could significantly decrease the accumulation of Gr-1+CD11b+ cells in an enlarged spleen, which have been demonstrated to be associated with tumor progression. Finally, we showed that 6 Gy whole body irradiation could delay the recurrence of Lewis lung carcinoma after local irradiation by reducing the accumulation of Gr-1+CD11b+ cells.

We exhibited that CD11b+ myeloid cells in the irradiated tumors could functionally mimic CD31-expressing endothelial cells and α-SMA-expressing mural cells, and thereby increased the microvessel density and, in the same way, promoted tumor recurrence. These results indicated that Gr-1+CD11b+ cells could enhance vasculogenesis to promote MVD in the irradiated tumors and might play an important role in the tumor recurrence after irradiation. Different studies yielded different results concerning the roles of bone marrow-derived cells in tumor neo-vasculature, and the discrepancies might partly be due to different models used. Our data also showed that Gr-1+CD11b+ myeloid cells were mostly the bone-marrow cells and spleen cells in tumor bearing mice (Fig. 1A), suggesting that Gr-1+CD11b+ myeloid cells may play a more important role than other CD11b+ cells in tumor neo-vasculature. This speculation warrants further study.

Some studies reported that myeloid inflammatory cells, after being recruited to tumor tissues, could directly incorporate into the existing blood vessels and/or secrete pro-angiogenic factors, such as MMP-9 and iNOS, to promote tumor recurrence after irradiation. CD11b+ cells could express high level of matrix metalloproteinase-9 (MMP-9), which has been found to play a crucial role in tumor vasculogenesis in a pre-irradiated model, and promote tumor angiogenesis. CD11b-positive myelomonocytic cells from the transplanted BM were responsible for tumor growth and the development of immature blood vessels in MMP-9 knockout mice receiving wild-type BM. This suggests that MMP-9 also plays an important role in tumor neo-vasculature after irradiation. More interestingly, our data showed that more than 95% infiltrated CD11b+ cells expressed iNOS, partly owing to the high expression of NF-κB after irradiation. As a signaling molecule, NO (Nitric oxide) regulates various vascular functions, including angiogenesis, blood flow, vascular permeability and micro-lymphatic flow. The elevated expression of iNOS (inducible nitric oxide synthesis) in infiltrating CD11b+ cells after irradiation showed that iNOS might play an important role in the revascularization. Various studies also showed that NO could both promote and inhibit tumor progression and metastasis. The effects of NO in tumors seem to depend on the activity and localization of NOS isoforms, concentration, duration of NO exposure, and cellular sensitivity to NO. The effect of altered NO levels on tumor growth and angiogenesis has also been well studied by pharmacological manipulation with either NO donors or NOS inhibitors. Treatment of mice bearing mammary and squamous carcinomas with NG-nitro-L-arginine methyl ester,
a universal NOS inhibitor, as well as specific inhibition of iNOS by either 1400 W or L-nil, reduced subcutaneous tumor growth and vessel development. A single dose of the NOS inhibitor NG-nitro-L-arginine (L-NNA) was shown to induce an acute and sustained reduction in human tumor blood volume, providing clinical evidence that inhibition of NOS has anti-tumor vascular effects. The importance of host-derived NO for tumor growth has also been genetically investigated in iNOS knockout mice, in which tumor growth and vascularization were decreased. Although tumor cells are also a major source of NO, which can affect angiogenesis and modulate tumor progression, our data showed that, after irradiation, most of the NO came from the mesenchymal cells.

To sum up, our results showed that Gr-1⁺CD11b⁺ cells were associated with tumor progression and could promote tumor recurrence after irradiation by enhancing tumor neovascularization. Moreover, recruited CD11b⁺ cells highly expressing iNOS may play an angiogenic role in tumor neovascularization. Then whole body irradiation of 6 Gy was proven to be an effective way to delay the recurrence in LLC-bearing mice after local irradiation by depleting the accumulation of Gr-1⁺CD11b⁺ cells, especially in the spleen. More interestingly, irradiation of enlarged spleen might provide a novel alternative of anti-angiogenesis therapies.

**Methods**

**Mice.** Male C57BL/6 mice, aged 8–10 weeks, were purchased from Beijing University (Beijing, China). The mice were maintained on a chow diet on a 12-hour light/12-hour dark cycle at 25°C in the Animal Care Facility of Tongji Medical College by strictly following the institutional guidelines.

**Cell culture.** Lewis lung carcinoma (LLC) cells were obtained from the American Type Tissue Collection (Manassas, Virginia, USA) and maintained by employing standard cell culture techniques. LLC cells were cultured in RPMI 1640 supplemented with 10% FBS (Gibco, Grand Island, NY).

**Tumor models.** Lewis lung cancer cells (5 × 10⁶) were injected subcutaneously (s.c.) onto the back of the mouse approximately 1 cm proximal to the base of the tail. Tumors were measured with a caliper and tumor volumes (mm³) were calculated by the following formula: Volume = length × width² × π/6.

**Treatment of animals.** Treatments were initiated when the mean diameter of tumor reach 0.75 cm. The tumor-bearing mice were given 20 Gy local irradiation (LI) or 14 Gy local irradiation in combination with 6 Gy sublethal whole body irradiation (WBI) to suppress the bone marrow and temporarily deplete leukocytes. Some
mice were injected AMD3100 (Sigma-Aldrich, at 5 mg/kg i.p., twice a day), a specific CXCR4 inhibitor. On the third day, mice were administered 20 Gy LI 2 hours after mice were injected AMD3100 (Sigma-Aldrich, at 5 mg/kg i.p., twice a day), a specific

10% SDS-PAGE, transferred to nitrocellulose membrane and then incubated for Western blot analysis criteria for determining a vessel profile32 were used. Any stained endothelial cell or Dil-Staining cells (1

dilution. The primary antibodies against NF-kB p65 (ab31481, Abcam) or iNOS (ab15323, Abcam) were purchased from Abcam. β-actin was from Santa Cruz Biotechnology Inc.

Histological assessment. For CD11b+ cells in tumors, only DAPI-positive (viable cells) areas were subjected to confocal microscopy33. The ratios of MMP-9 +, iNOS +, CD11 +, α-SMA + cells to CD11b+ cells in the selected fields were calculated as percentage of CD11b+ positive area. Images were captured using a LMS10 confocal microscope (ZEISS, Germany), and were analyzed by using Image-Pro Plus 6.0 software package (Media Cybernetics, MD). For each tumor, five fields were randomly selected from immunohistochemically or immunofluorescently stained slices, and with each group, 5 to 6 tumors were studied.

Flow cytometrical analysis of NO. Single-cell suspension was made from resected tumors. The cells were incubated with 5 μM fluorescent probe DAF-FM DA (3-amino-5-methyl-7-diethylamino, diacetoxybenzilimine) in the dark at 37 °C for 30 minutes. The cells were rinsed with HEPES-NaOH (pH 7.5) three times (2 min each time) to remove excess fluorescence and further incubated in the dark in probe-free medium (30 min, 37 °C) before flow cytometric analysis (FACScalibur, BD).

Ethics statement. All experiments were approved by the local ethics committee for animal welfare (Animal Care and Utilization Committee of Huazhong University of Science and Technology, Wuhan, China) and complied with the guidelines for the welfare of animals for experimental cancer research34. All surgeries and irradiation procedures were performed under sodium pentobarbital anesthesia, and efforts were made to minimize the animal suffering.

Statistical analysis. All data were expressed as mean ± SEM. Differences among groups were evaluated by ANOVA or the unpaired Student’s t-test by using GraphPad Prism5 software. A P value <0.05 was considered to be statistically significant.

Flow cytometrical analysis of NO. Single-cell suspension was made from resected tumors. The cells were incubated with 5 μM fluorescent probe DAF-FM DA (3-amino-5-methyl-7-diethylamino, diacetoxybenzilimine) in the dark at 37 °C for 30 minutes. The cells were rinsed with HEPES-NaOH (pH 7.5) three times (2 min each time) to remove excess fluorescence and further incubated in the dark in probe-free medium (30 min, 37 °C) before flow cytometric analysis (FACScalibur, BD).

Ethics statement. All experiments were approved by the local ethics committee for animal welfare (Animal Care and Utilization Committee of Huazhong University of Science and Technology, Wuhan, China) and complied with the guidelines for the welfare of animals for experimental cancer research34. All surgeries and irradiation procedures were performed under sodium pentobarbital anesthesia, and efforts were made to minimize the animal suffering.

Statistical analysis. All data were expressed as mean ± SEM. Differences among groups were evaluated by ANOVA or the unpaired Student’s t-test by using GraphPad Prism5 software. A P value <0.05 was considered to be statistically significant.

**Acknowledgments**

This work was supported by the Hubei Provincial Natural Science Foundation. (Project No2009CDA061).

**Author contributions**

G.W. and T.L. designed the experiments. T.L. and C.X.Y. performed the experiments and analysed the data. S.Z., Y.C.L., L.L.S. and Y.M.F. help in the experiments. T.L., C.Y.X. and G.W. co-wrote the manuscript. D.D.Y., T.Z. and H.M. help in data collection, data analysis and manuscript writing. All authors discussed the results and commented on the manuscript.
