As part of an ongoing study of new insulin mimetic agents from medicinal plants, the 70% EtOH extract of *Symplocos cochinchinensis* was found to have a stimulatory effect on glucose uptake in 3T3-L1 adipocyte cells. The intensive targeted isolation of this active extract resulted in ten new hydroxyoleoside-type compounds conjugated with a phenolic acid and monoterpene (1–6 and 8–11), as well as four known compounds (7 and 12–14). The chemical structures of the new compounds were determined based on spectroscopic data analysis (\(^1\)H and \(^13\)C NMR, HSQC, HMBC, NOESY and MS). The absolute configurations of the isolated compounds were determined by electronic circular dichroism (ECD) analysis of derivatives obtained after a series of reactions, such as those with dirhodium (II) tetrakis (trifluoroacetate) and dimolybdenum (II) tetraacetate. In vitro, compounds 3, 7 and 8 moderately increased the 2-deoxy-2-[(7-nitro-2,1,3-benzoxadiazol-4-yl)amino]-D-glucose (2-NBDG) uptake level in differentiated 3T3-L1 adipocytes. For further studies, we evaluated their effects on the expression of glucose transporter-4 (GLUT4), its translocation, protein tyrosine phosphatase 1B (PTP1B) inhibition and expression of phosphorylated Akt. Our results strongly suggest that the traditional uses of this plant can be described as active constituents by hydroxyoleoside-type compounds.

Globally, the number of people with diabetes mellitus is growing rapidly, and the incidence rate of diabetes is also accelerating, especially as the elderly and obese population increases. The number of patients with diabetes is expected to increase from 171 million in 2000 to 366 million globally by 2030. According to the American Diabetes Association, the incidence of diabetes is approximately 25.2% of the total elderly population in the United States and 12.0 million seniors suffered from diabetes in 2015. As the increase in diabetic patients is associated with a dramatic increase in the cost of diabetes-related complications, direct healthcare costs and productivity losses in the US alone are estimated to be $ 176 billion and $ 69 billion in 2012, respectively.

Diabetes is a chronic disease that occurs when the pancreas does not produce enough insulin (type 1 diabetes) or the insulin produced does not function effectively at the site of action (type 2 diabetes, T2D). When insulin does not function properly, the increased blood sugar in the body can cause serious damage to the heart, blood vessels, kidneys, eyes and nerves. Since T2D associated with insulin resistance is the most prevalent, it is urgently necessary to develop new anti-diabetic agents, especially those of targeting type 2 diabetes.

While many diabetes medications lower blood glucose levels in the short term, they often cause weight gain as a side effect and prolonged use worsens the insulin resistance of diabetic patients. Insulin mimetics used as oral diabetic agents, which act similar to insulin but do not synthesize fats, have been suggested as a good solution for the treatment for diabetes. Interestingly, food intake and body weight decrease when insulin is selectively delivered to the brain, but not when it is delivered to the whole body. These results suggest that insulin mimetics that separate glucose-lowering action from the weight gain are a very good pharmacological solution for overcoming insulin resistance as the side effects of diabetes therapies.

*Symplocos cochinchinensis* (Lour.) S. Moore ([www.theplantlist.org](http://www.theplantlist.org)) is an evergreen tree that grows up to 35 meters in height and belongs to the Symplocaceae family. This plant is distributed in East Asia, including China, Japan, India, Vietnam and Malaysia. Ethnobotanical uses of this plant include treatment of diabetes mellitus in traditional “Ayurvedic” Indian medicine. There are several reports on extracts from this plant showing...
antidiabetic, antilipidemic and antioxidant activity, but there have been few studies on the chemical constituents of Symplocos cochinchinensis. The genus Symplocos contains a large amount of seco-iridoid and phenolic compounds. Recent reports on the antidiabetic activity of oleuropein, which is abundant in olive tree leaves, led us to isolate active compounds by a special dereplication method aimed at seco-iridoids.

In the search for new insulin mimetics from S. cochinchinensis, the 70% EtOH extract of the plant showed a moderate increase in glucose uptake in differentiated adipocyte cells. Bioassay-guided fractionation resulted in the isolation of ten new hydroxyoleoside-type compounds, including eight phenolic hydroxyoleosides, symplocochinside A–H (1–6, 8 and 9), and two monoterpene-derivatized hydroxyoleosides, symplocochinside I–J (10–11), along with four known compounds, including a megastigmane and triterpene glycosides (Fig. 1). The absolute configurations of the monoterpene attached to hydroxyoleoside (10) and megastigmane (12) were assigned by chemical methods coupled with spectroscopic analysis. All isolates were evaluated for glucose uptake level, GLUT-4 translocation, PTP1B activity and Akt phosphorylation. In this paper, we report the isolation, structural elucidation, determination of absolute configuration and anti-diabetic properties of these isolates.

Results and Discussion

Structural elucidation of new compounds. The 70% EtOH extract of the aerial part of S. cochinchinensis was separated by silica gel, Sephadex LH-20, ODS open column chromatography and preparative HPLC to yield ten new 10-hydroxyoleoside-type seco-iridoids, symplocochinsides A–F (1–6) and G–J (8–11), together with four known compounds (Fig. 1).
Symplocoschinside A (1) was obtained as a brownish gum, and the molecular formula was established as C_{25}H_{30}O_{14} by HREIMS, which showed a ion peak at m/z 605.1478 [M + Na]^+ (calcd for C_{25}H_{30}NaO_{15}, 605.1477). The IR spectrum of 1 showed the presence of hydroxyl (3351 cm⁻¹), carboxylic (1692 cm⁻¹) and olefinic (1599 cm⁻¹) functionalities. The ¹H NMR spectrum (Table 1) of 1 displayed the typical signals of the 10-hydroxyleoside skeleton, which is considered an important biosynthetic precursor as one of the major types of seco-iridoids, including one acetal proton of H-1 (δ_H 5.90, br s), two vinyl protons of H-3 (δ_H 7.46, br s), one methine group of H-5 (δ_H 3.88, br d, J = 9.6 Hz), one methylene group of H-6 ([δ_H 2.68, d, J = 14.4 Hz] and [δ_H 2.37, dd, J = 15.2, 10.4 Hz]), one olefinic proton of H-8 (δ_H 6.02, t, J = 6.4 Hz) and oxymethylene protons of H-10 ([δ_H 4.94, dd, J = 13.6, 8.8 Hz] and [δ_H 4.80, dd, J = 12.8, 4.8 Hz]). The corresponding seco-iridoid carbon signals, which consisted of 26 carbon resonances (Table 2) from the ¹³C NMR spectrum of compound 1, were observed at δ_C 92.0 (C-1), 152.3 (C-3), 109.0 (C-4), 31.1 (C-5), 40.0 (C-6), 122.3 (C-8) and 133.2 (C-9), as well as one oxygenated methylene carbon at 60.4 (C-10) and two carbonyl carbons at δ_C 172.8 (C-7) and 167.5 (C-11). Further analysis of the HMBC data of compound 1 (Fig. 2) confirmed the presence of a 10-hydroxyleoside containing pyran ring moiety by the key correlations from H-8 (δ_H 6.02, t, J = 6.4 Hz) to C-1/C-5, from H-3 to C-1 and from H-10a/H-10b of the oxymethylene to C-8/C-9. In addition, HMBC correlations of H-5 with C-3/C-7/C-11 and of H-3 with C-11 indicated the positions of the carboxylic functionalities. The relatively large coupling constant (7.2 Hz) for the anemic proton and six typical carbon resonances at δ_C 99.1 (C-1″), 73.3 (C-2″), 76.6 (C-3″), 70.0 (C-4″), 77.4 (C-5″) and 61.1 (C-6″) suggested the presence of a β-glucopyranosyl group. The splitting patterns of H-2′ (δ_H 7.32, d, J = 1.6 Hz), H-5′ (δ_H 6.79, d, J = 8.0 Hz) and H-6′ (δ_H 7.12, dd, J = 8.0, 0.8 Hz) in the lower field indicated the presence of a benzene ring with an ABX spin system. The key HMBC correlations from OMe (δ_H 3.80, s) to δ_C 148.0 (C-3′) and the carbon resonance at δ_C 149.4 (C-4′) are indicative of the presence of one methoxy and one hydroxy group, respectively. The large coupling constant between H-7′ (δ_H 7.55, d, J = 16.0 Hz) and H-8′ (δ_H 6.49, d, J = 16.0 Hz), the benzene ring system and the distinct UV absorption maximum at 324 nm strongly suggested the presence of a ferulic acid group with α,β-unsaturated ketone moiety. The HMBC correlation from H-10 to C-9 at δ_C 166.5 proved that the ferulic acid moiety is linked to C-10 of hydroxyleoside. The ROESY correlations of compound 1 (Fig. 2) suggested that the C-8 is in the E configuration and H-5 is in the β orientation because H-5 and H-10 become closer to each other, while the H-1/H-1′ and H-1′/H-6 are on the same plane. Therefore, the relative configuration could be determined easily as [15S, 5S]⁰. The electronic circular dichroism (ECD) spectrum of 1 with oleuropein¹² displayed a negative Cotton effect (CE) at 226 nm (Fig. 3A) arising from the L⁰ band of the 4-carboxy-5,6-dihydro-[1H]-pyranophromoneⁱ³. Since compound 1 assumes a distorted dihydropyran conformation¹⁴ and the helicity rule is applicable in this case, the CE with shorter wavelength predicts the 1S and 55 configurationⁱ⁵. In addition, chemical shifts of compounds with the 1S configuration generally appeared at approximately 94–96 ppm, while oleuropein with the 1α configuration showed a chemical shift of 105.7 ppm in CD₂OD². Thus, compound 1 was determined as 10-O-trans-feruloyl-10-hydroxyleoside with 1S and 55 (Fig. 1)⁴.

Symplocoschinside B (2) was purified as a brownish gum, and its molecular formula was established as C_{25}H_{30}O_{14} from the HRESI mass data, which showed a ion peak at m/z 605.1476 [M + Na]^+ (calcd for C_{25}H_{30}NaO_{15}, 605.1477). The 'H NMR data of compound 2 (Table 1) were similar to those of 1 except for the configuration of the ferulic acid double bond. The J values of H-7′ (δ_H 6.86, d, J = 13.0 Hz) and H-8′ (δ_H 5.78, d, J = 13.0 Hz) of compound 2 indicated that 2 is 10-O-trans-configured compound. The ¹H NMR of compound 2 was determined by the retention time and abundance when the partial extract of S. cohinehisensis was co-injected with 2 on LC/MS. Hence, the structure of 2 was characterized as 10-O-cis-feruloyl-10-hydroxyleoside.

Symplocoschinside C (3) (Fig. 1) was isolated as a brown gum, and its molecular formula was established as C_{25}H_{30}O_{14} by HREIMS mass spectrum, which showed a ion peak at m/z 575.1371 [M + Na]^+ (calcd for C_{25}H_{30}NaO_{15}, 575.1371). The unique UV patterns of 3, which indicate the presence of a cinnamic acid moiety, and the characteristic proton peaks of H-1 (δ_H 5.90, s) and H-3 (δ_H 7.46, br s) showed the common features of this seco-iridoid. The 'H and ¹³C NMR spectra of 3 were similar to those of 1 except for the absence of the methoxy group. Since the trans-cinnamic acid derivative can be converted to the cis-isomer through photoisomerization¹⁸, the structure of compound 3 was determined after conversion to the trans form by the reaction with iodoine¹⁹. Thus, the structure of 3 was determined as 10-O-trans-p-coumaroyl-10-hydroxyleoside.

Symplocoschinside D (4) was obtained as a brownish gum, and its molecular formula was established as C_{25}H_{30}O_{14} from the HRESI mass spectrum with a peak at m/z 575.1381 [M + Na]^+ (calcd for C_{25}H_{30}NaO_{14}, 575.1371). The ¹D NMR spectra of 4 (Tables 1 and 2) showed almost same patterns as those of 3 except for the coupling constants of H-7′ (δ_H 6.87, d, J = 11.2 Hz) and H-8′ (δ_H 5.77, d, J = 12.8 Hz), indicating that compound 4 is the cis-isomer of compound 3. The pure form of cis-configured compound 4 could be obtained. Hence, the structure of 4 was identified as 10-O-cis-p-coumaroyl-10-hydroxyleoside.

Symplocoschinside E (5) (Fig. 1) was isolated as a brownish gum, and its molecular formula was established as C_{25}H_{30}O_{14} from the HRESI mass spectrum, which showed a sodium adduct ion peak at m/z 619.1673 [M + Na]^+ (calcd for C_{25}H_{30}NaO_{13}, 619.1633). The NMR spectra of 5 (Tables 1 and 2) were similar to those of 1 except for one additional methoxy group. The HMBC correlations (Supplementary Fig. S18) of 5 showed one methoxy at δ_C 152.9 (C-4′), of H-2′/H-6′ with C-4′ and of H-5′ with C-3′ revealed that the benzene ring had two methoxy groups at the para and meta positions. The coupling constants of H-7′ (δ_H 7.63, d, J = 15.9 Hz) and H-8′ (δ_H 6.39, d, J = 15.9 Hz) are indicative of the trans-configuration. Accordingly, the structure of 5 was assigned as 10-O-trans-3′,4′-dimethoxyxannamoyl-10-hydroxyleoside.

Symplocoschinside F (6), a brownish gum, had the molecular formula C_{24}H_{18}O_{10} as deduced from the HRESI mass spectrum, which showed a deprotonated ion peak at m/z 625.1776 [M − H]^− (calcd for C_{24}H_{18}O_{10}, 625.1774). The NMR spectra of 6 (Tables 1 and 2) were similar to those of 5 except for one additional methoxy groups, which is supported by the HMBC correlation (Supplementary Fig. S22) of 6 at δ_H 3.86, s with the carbon at 154.8 (C-5′). The coupling constants of H-7′ (δ_H 7.62, d, J = 15.9 Hz) and H-8′ (δ_H 7.96, d, J = 11.9 Hz) and H-8′ (δ_H 7.56, d, J = 11.2 Hz) and H-9′ (δ_H 6.39, d, J = 12.8 Hz) showed the common features of this seco-iridoid.

Table 1. $^1$H NMR data of compounds 1–6 and 8–11 ($\delta$ in ppm, J in Hz). $^a$Data were measured in DMSO-$d_6$ at 800 MHz. $^b$Data were measured in CD$_3$OD at 800 MHz.
The key HMBC correlation (Supplementary Fig. S38) of compound 10 showed the presence of 10 peaks other than the carbon peaks of 10-hydroxyoleoside (Supplementary Figs S33 and S34), which are three sp³ primary carbons, three sp³ methylene carbons and one sp³ quaternary carbon with a deshielded chemical shift (C-3, 134.5 ppm) implying the presence of one oxygenated quaternary carbon, one carbonyl group, and two olefinic carbons. The HMBC correlations of H-10 with C-1", H-9" with C-2"/C-4", of H-6" with C-4"/C-5", of H-5" with C-3" and of H-4" with C-2"/C-5" suggested the connectivity of the 10-hydroxyoleoside skeleton with 3-hydroxydimethyloctenoic acid, which is a monoterpenol also known as 3-hydroxycitronellic acid. The isolation of 3-hydroxycitronellic acid from 10 by selective hydrolysis was not successful due to racemization (data not shown). Therefore, after the reaction with dirhodium (II) tetrakis (tri-fluorooacetate), the empirical ECD method was employed for the determination of the absolute configuration at C-3".

The acetate form of compound 10 was purified after the peracetylation reaction (Supplementary Table S1) and was subjected to complexion with [Rh₆(OCCF₃)₁₂] in CDCl₃. According to the bulkiness rule, the negative Cotton effect at 350 nm (band E) was observed (Fig. 3B), which means that the absolute configuration of C-3" is 3'R. Thus, compound 10 was elucidated as (3'R)-10-O-3"-hydroxyterreinyl-10-hydroxyoleoside.

Table 2. ¹³C NMR data of compounds 1–6 and 8–11 (δ in ppm). Data were measured in DMSO-d₆ at 200 MHz. Data were measured in CD₃OD at 200 MHz. These values can be interchangeable. Peaks too small to be observed.
by the comparison with previously reported data\textsuperscript{23}. Thus, the structure of compound 11 was elucidated as 10-O-geranyl-10-hydroxyoleoside.

Compound 12 (Fig. 1) was obtained as a brownish gum, and its molecular formula was established as C\textsubscript{13}H\textsubscript{20}O\textsubscript{3} from the HRESI mass spectrum with a peak at m/z 225.1484 [M + H]\textsuperscript{+} (calcd for C\textsubscript{13}H\textsubscript{21}O\textsubscript{3}, 225.1485). The comparison with previously reported NMR data\textsuperscript{24} showed the compound has the same planar megastigmane structure (Supplementary Table S1). However, the NOESY spectrum (Supplementary Fig. S43) indicated the possibility of different configurations at C-8 and C-9 from those of the known compound 8,9-dihydromegastigmane-4,6-diene-3-one. In the NOESY spectrum, the correlations between H-7 at \(\delta_H 6.06\) (d, \(J = 9.2\) Hz)/H-13 at \(\delta_H (2.15, d, J = 0.8\) Hz) and H-8 at \(\delta_H (4.68, dd, J = 9.4, 5.3\) Hz)/H-9 at \(\delta_H (3.75, m)\) indicated that the olefinic carbon of C-7 is in the \textit{E} configuration and that the relative configuration of C-8 and C-9 is [8\textit{R}\textsuperscript{*}, 9\textit{S}\textsuperscript{*}]. The specific rotation of the known compound is \(+54.0\) (c 1.52 MeOH), whereas that of 12 was \(-88.9\) (c 0.2 MeOH). Since the planar structure of the known compound was reported without the absolute configuration, the absolute configuration of compound 12 was determined by the helicity rule using the ECD measurement after derivatization with dimolybdenum tetraacetate\textsuperscript{25,26}. It is possible to apply this method because compound 12 is erythro-1,2-diol and there is a bulkiness difference between the two substituents around the hydroxyl groups. The CD measurement after complexation with [Mo\textsubscript{2}(OAc)\textsubscript{4}] showed a negative CE in the band II region (403 nm, \(-0.15\) mdeg) used as the diagnostic band (Fig. 3C). Accordingly, the structure of 12 was determined as (8\textit{R},9\textit{S})-8,9-dihydromegastigmane-4,6-diene-3-one.

Based on NMR, MS and optical rotation data and comparison with literature values, the known compounds were elucidated as, 10-cinnamoyloxyoleoside (7)\textsuperscript{27}, (8\textit{R},9\textit{S})-8,9-dihydromegastigmane-4,6-diene-3-one (12)\textsuperscript{24}, nigaichigoside F1 (13)\textsuperscript{28}, and trachelosperoside A1 (14)\textsuperscript{29} (Fig. 1).

**Measurements of insulin mimetic activity with 2-NBDG on differentiated 3T3-L1 adipocytes.**

Unlike the insulin in the brain, insulin at the periphery acts as an anabolic factor and causes weight gain as a side effect if the energy usage of the patient is not increased. Insulin mimetics have similar characteristics to insulin in terms of the reduction in food intake and body weight in rats when administered intracerebroventricularly.
Considering the abovementioned difference, insulin mimetics appear to be more advantageous than insulin because of their potential to pass through the blood-brain barrier (BBB), which allows us to find insulin mimetics from natural resources with fewer side effects. To measure for insulin mimetics, the 2-NBDG assay, which is used a fluorescent-tagged glucose analogue for monitoring the glucose uptake in cells, was introduced. All isolates (1–14) were evaluated for 2-NBDG uptake in differentiated 3T3-L1 adipocytes at a concentration of 40 μM (Fig. 4A and Supplementary Fig. S49). Most of the phenolic acid- derivatized seco-iridoid showed activity, whereas compound 9 with an acetyl group and compound 10 with a monoterpene showed weak activity. Comparison of the activities of the compounds with the trans and cis forms showed that the trans isomers had stronger activity than cis. Among these compounds, compounds 3, 7 and 8 showed stronger activities compared to others. Thus, fluorescent signals measurement was performed using a fluorescence microscopy for assessing the transport efficacy of 2-NBDG into cells. Increased signal intensities after treatment of the compounds were more strongly observed in cells treated with 3, 7 and 8 at 40 μM compared to those in cells of the control group (DMSO, Fig. 4B). It was also observed that selected compounds 3, 7 and 8 increased the 2-NBDG uptake in a dose-dependent manner (Fig. 5A,B). Taken together, these results suggest that derivatization of seco-iridoids with trans-configured phenolic acids is relevant to activity. These results are consistent with the ethnopharmacological history of this plant as a diabetes remedy in Ayurvedic formulations.
GLUT4 translocation by selected compounds in the differentiated 3T3-L1 adipocytes. Concentrations of plasma glucose levels are normally regulated by glucose transporter proteins in muscle and adipose tissue. Among the 14 sugar transporter proteins, GLUT4 is the principal isoform that plays a major role in glucose homeostasis. Intracellular glucose uptake occurs via GLUT4 recruitment to the cell surfaces of muscle and adipose cells. GLUT4 trafficking is stimulated acutely by both insulin via the PI3K/Akt pathway and exercise via the AMPK pathway. Therefore, the potential of insulin mimetics can be estimated partially by the measurement of GLUT4 translocation or/and expression. Compounds 3, 7 and 8, which showed activity in the 2-NBDG assay, were subjected to the measurement of GLUT4 translocation in the plasma membrane. Western blot analysis showed increased GLUT4 translocation in the plasma membrane of differentiated adipocytes upon treatment with the compounds at 40 μM (Fig. 5C). Compound 3 (40 μM) and insulin (100 nM) clearly increased GLUT4 expression in whole cell lysate, while compounds 7 and 8 showed relatively weak effects on expression of GLUT4 in adipocytes (Supplementary Figs S52 and S57). However, compounds 3, 7 and 8 significantly induce the expression of phosphorylated Akt (Supplementary Figs S61 and S62). These results provide insight into how these molecules stimulate glucose uptake through up-regulation of the Akt pathway. The present data strongly indicate that compound 3 promotes glucose uptake by GLUT4 translocation associated with increased level of GLUT4 expression. Although the mechanism of 3 is still unclear and further studies are in need near future, we propose this compound could regulate the glucose metabolism and insulin sensitivity.

Protein tyrosine phosphatase 1B (PTP1B) inhibitory activity of isolated compounds. Upon insulin binding, glucose uptake is increased by a series of signals including phosphorylation of the insulin receptor (IR), transformation of phosphatidylinositol (4,5)-bisphosphate (PIP2) to phosphatidylinositol (3,4,5)-triphosphate (PIP3) by phosphatidylinositol 3-kinase (PI3K), activation of Akt, and translocation of GLUT4. PTP1B exerts negative regulation of insulin and leptin receptor signalling by dephosphorylation of activated IR and Janus kinase. Since some seco-iridoids increased glucose uptake through 2-NBDG and GLUT4 translocation, the PTP1B inhibitory activity, which is important in the relevant signal transduction process, was...
also assessed. When all isolated compounds were subjected to the PTP1B assay, compound 3 was found to be a good candidate for use as a PTP1B inhibitor, whereas 7 and 8 showed moderate activity at 50 μM (Supplementary Fig. S53). Among these compounds, the IC₅₀ of 3 is 19.54 ± 0.76 μM, showing moderate activity compared to the positive control tested (Supplementary Fig. S54). Compound 3 was further examined in kinetic experiments and was shown to inhibit PTP1B in a non-competitive manner at different concentrations (10, 20 and 40 μM, respectively) on the PTP1B enzyme. Molecular docking analysis of compound 3 into the active site of PTP1B enzyme (PDB code 1Q6T) was performed according to the CDOCKER protocol in the CHARMM-based docking algorithm. As shown in Fig. 5E, the C-7 carboxylic acid group forms a conventional hydrogen bond and a carbon-hydrogen bond with...
Asp548 and GLY759, respectively. Moreover, the benzene ring shows affinity for Phe682 via a π–π interaction (Supplementary Fig. S55). These key residues have been proposed as active sites A and B of PTP1B. Additionally, the CDOCKER interaction energy was calculated to be −61.18 kcal/mol. Overall, the observed effects appear to contribute to the inhibitory activity of compound 3 against PTP1B.

Conclusions

In this paper, eight new analogues of phenolic acid-conjugated 10-hydroxoyleoside type (1–6 and 8–9) and two new monoterpene-conjugated compounds (10 and 11), along with one known seco-iridoid (7), one megastigmane (12) and two triterpenoids, (13–14) were isolated from S. cochinchinensis. The absolute configurations of these compounds were determined by ECD analysis, dirhodium (II) tetrakis (trifluoroacetae) reaction or dimolybdenum (II) tetractetrae reaction. Compounds 3, 7 and 8 exhibited 2-NBDG uptake increasing activity in differentiated 3T3-L1 adipocytes by GLUT4 translocation which was evident in Western blot analysis. Compound 3 increased GLUT4 expression level and direct GLUT4 translocation through the PI3K/Akt pathway via a PTP1B inhibition. These results also imply the structure activity relationship to some degree such that derivatization with a phenolic acid and trans configuration contribute to the activity. In conclusion, investigation of new seco-iridoids as anti-diabetic compounds enriches the chemical profile of S. cochinchinensis and provides evidence for the traditional ethnopharmacological uses of this plant.

Methods

General experimental procedures. Optical rotations were recorded on a JASCO P-2000 polarimeter (JASCO International Co. Ltd., Tokyo, Japan). ECD spectra were measured using Chirascan plus (Applied photophysics Ltd., Surrey, United Kingdom). IR data were obtained using a Nicolet 6700 FT-IR spectrometer (Thermo Electron Corp., Waltham, MA, USA). The 1D and 2D NMR spectra were obtained in deuterated solvents using an AVANCE 800 MHz spectrometer (Bruker, Germany). HRESIMS values were obtained using an Agilent Technologies 6530 Q-TOF MS spectrometer (Agilent Technologies, Inc., Santa Clara, CA, USA). Regular column chromatography (CC) was carried out with silica gel (particle size: 63–200 μm, Zeocem, Lake Zurich, Switzerland), RP-C18 (particle size: 75 μm, nacalai tesque, Kyoto, Japan), and Sephadex LH-20 (GE Healthcare, Little Chalfont, UK). Silica gel 60 F254 and RP-18 F256 TLC plates were obtained from Merck (Darmstadt, Germany). A Gilson HPLC purification system was used at a flow of 2 mL/min and UV detection at 205, 254, and 300 nm using an Optima Pak C18 column (10 × 250 mm, 5 μm particle size; RS Tech, Seoul, Korea) and a COSMOSIL 5C18-MS-II column (10 × 250 mm, 5 μm particle size; Nacalai Tesque, Kyoto, Japan). Analytical-grade solvents were used for extraction and isolation.

Plant material. S. cochinchinensis was collected in Kim Boi district, Hoa Binh province, Vietnam and authenticated by Dr. Tran Van On, Head of the Department of Botany, Hanoi University of Pharmacy, Vietnam. A voucher specimen (SCL-02) was deposited at the Korea Bioactive Natural Material Bank, Research Institute of Pharmaceutical Sciences, College of Pharmacy, Seoul National University, Seoul, Republic of Korea.

Extraction and isolation. The stems and leaves of S. cochinchinensis (4 kg) were extracted with 70% EtOH (4 × 17 L, 4 h each) at 60°C. The combined extract was concentrated by an evaporator to yield a dried residue (752.6 g). Dried extract was suspended in H2O and then partitioned with CH2Cl2 (4.4 mg), EtOAc (16.0 mg). F.5.2 (730 mg) was subjected to semi-prep HPLC with a MeCN/H2O (v/v, 28/72 to 32/68), resulting in the isolation of compounds (1.5 mg) and (4 (3 mg)). F.5.3 (11.2 mg) and (3 (5.5 mg)) were purified from F.5.1.2 with ODS silica gel HPLC and eluted with MeCN/H2O (v/v, 19/81 to 21/79). F.5.1 (566.4 mg) was subjected to reversed-phase chromatography (2 × 50 cm) with 5% MeOH to give six subfractions (F.5.1.1–F5.1.6). Compound 8 (4 mg) was purified from MeCN/H2O (v/v, 24/76). F.5.1.1.1 was subjected to semi-prep HPLC with MeCN/H2O (v/v, 12/88), resulting in the isolation of compound 9 (16.0 mg). F.5.2 (730 mg) was subjected to reversed-phase chromatography with 40% MeOH to obtain six subfractions (F.5.2.1–F5.2.6). F.5.2.3 was subjected to semi-prep HPLC with MeCN/H2O (v/v, 23/77), resulting in the isolation of compounds 5 (1.5 mg) and 6 (0.5 mg). F.5.3 was separated by Sephadex LH-20 CC into two subfractions (F.5.3.1–F5.3.2). Subfraction F.5.3.1 was subjected to semi-prep HPLC with MeCN/H2O (v/v, from 28/72 to 32/68), resulting in the isolation of compound 10 (3 mg). Subfraction F.5.3.2 was subjected to semi-prep HPLC with MeCN/H2O (v/v, 28/72 to 32/68), resulting in the isolation of compound 7 (1.6 mg). Subfraction F.5.3.1 was subjected to Sephadex LH-20 and reversed-phase column sequentially, resulting in the isolation of compound 13 (7.7 mg). Subfraction F.5.6 was subjected to a reversed-phase column (3.5 × 50 cm) and eluted with 10% MeCN and compounds 11 (1.9 mg) and 14 (5.1 mg) were isolated from subfraction F.5.6.1 and F.5.6.2, respectively by semi-prep HPLC with MeOH/H2O (v/v, 55/45 to 61/39). E.2 was subjected to direct semi-prep HPLC with MeCN/H2O (v/v, 19/81 to 21/79), resulting in the isolation of compound 12 (2.2 mg).

10-O-trans-Feruloyl-10-hydroxyoleoside (1). Brownish gum; [α]D20 224 (2.3), 324 (1.9) nm; IR νmax 3350, 2918, 2352, 1692, 1599, 1393, 1161 cm−1; 1H and 13C NMR, see Tables 1 and 2; HRESIMS m/z 605.1478 [M + Na]+ (calcd for C26H30NaO15, 605.1477).

10-O-trans-3′,4′,5′-Trimethoxycinnamoyl-10-hydroxyoleoside (6). Brownish gum; [α]D20 +106.1 (c 0.50, MeOH); UV (MeOH) λmax (log ε) 323 (1.8), 306 (1.6) nm; IR νmax 2349, 2917, 2136, 1716, 1509, 1166 cm⁻¹; 1H and 13C NMR, see Tables 1 and 2; HRESIMS m/z 625.1776 [M – H]– (calcd for C32H31NaO15, 625.1774).

10-O-Benzoyl-10-hydroxyoleoside (8). Brownish gum; [α]D20 +159.2 (c 0.10, MeOH); UV (MeOH) λmax (log ε) 236 (2.3) nm; IR νmax 3428, 2972, 1705, 1278, 1055, 1014, 716 cm⁻¹; 1H and 13C NMR, see Tables 1 and 2; HRESIMS m/z 533.1292 [M + Na]+ (calcd for C26H35O13, 533.1266).

10-O-Acetyl-10-hydroxyoleoside (9). Brownish gum; [α]D20 +91.1 (c 0.10, MeOH); UV (MeOH) λmax (log ε) 226 (2.3) nm; IR νmax 3386, 2972, 1712, 1637, 1397, 1254, 1053 cm⁻¹; 1H and 13C NMR, see Tables 1 and 2; HRESIMS m/z 447.1149 [M – H]– (calcd for C20H33O10, 447.1144).

(T3’R)-10-O-3′-Hydroxycitronellol-10-hydroxyoleoside (10). Yellowish gum; [α]D20 +177.9 (c 0.10, MeOH); UV (MeOH) λmax (log ε) 226 (2.4) nm; IR νmax 3405, 2919, 2850, 2349, 1715, 1638, 1435, 1202, 1078, 672 cm⁻¹; 1H and 13C NMR, see Tables 1 and 2; HRESIMS m/z 573.2200 [M – H]– (calcd for C28H33O16, 573.2189).

Tetraacetate of compound 10 (10a). Colourless gum; [α]D20 +113.1 (c 0.10, MeOH); UV (MeOH) λmax (log ε) 233 (2.5) nm; IR νmax 3271, 2989, 1748, 1646, 1508, 1224, 676 cm⁻¹; 1H and 13C NMR, see supporting data; HRESIMS m/z 741.2621 [M – H]– (calcd for C30H41O14, 741.2611).

10-O-Geranyl-10-hydroxyoleoside (11). Yellowish gum; [α]D20 +91.1 (c 0.10, MeOH); UV (MeOH) λmax (log ε) 222 (2.4) nm; IR νmax 3316, 3121, 2894, 1748, 1646, 1508, 676 cm⁻¹; 1H and 13C NMR, see Tables 1 and 2; HRESIMS m/z 555.2088 [M – H]– (calcd for C28H33O14, 555.2083).

(8R,9S)-8,9-Dihydropseudoginsenoside-4,6-diene-3-one (12). Brownish gum; [α]D20 +88.9 (c 0.20, MeOH); UV (MeOH) λmax (log ε) 209 (2.3), 285 (2.6) nm; IR νmax 3400, 2972, 2360, 1649, 1387, 1033, 671 cm⁻¹; 1H and 13C NMR, see Tables 1 and 2; HRESIMS m/z 225.1484 [M + H]+ (calcd for C13H15O5, 225.1485).

Determination of absolute configuration of sugars. Compound 9 (1.0 mg) was hydrolysed by 0.5 M HCl (1.0 mL) at 90°C for 1 hour. The solvent was neutralized with Na2CO3 and concentrated in vacuo. L-Cysteine methyl ester hydrochloride in anhydrous pyridine (0.5 mg) was added to the resulting residue, followed by heating for 1 hour at 60°C. Phenyl isothiocyanate (0.1 mL) was added and heated at 60°C for 1 hour. The solution was then analyzed by reversed-phase HPLC under the following conditions: an INNO C18 column (5 mm, 4.6 x 250 mm, 5 μm); MeCN/H2O mobile phase (27:73, v/v); a diode array detector; a detection wavelength of 254 nm; and a flow rate of 0.6 mL/min. Comparison of the retention time of the derivative of compound 9 with that of the derivative of an authentic sample of D-glucose (retention time: 23.18 min) proved the D-configuration of the glucose moiety in compound 9.

Absolute configuration of the tertiary alcohol moiety in 10. Compound 10 (13.2 mg) was kept in pyridine/acetone, 1:1 (4 mL) at room temperature for 19 hours to give peracylated compound 10a. The mixture was neutralized with NaHCO3 and dried under vacuum. A colorless gum (10.6 mg, 80.3%) was obtained by extraction with EtOAc and the product was further purified to over 99% using prep-HPLC. Compound 10a (0.5 mg) was then dissolved in a dry solution of [Rh2(OCOCF3)4]2 (1.0 mg) in CDCl3 (600 μL). The resulting mixture was used for CD measurements and the obtained CD spectrum was compared with that of compound 10a for clarity. The Cotton effect at 350 nm (E band) was correlated with the absolute configuration of the tertiary alcohol[35].

Preparation of Mo6c-complexes of compound 12. The CD spectra were measured at room temperature in DMSO with 1.0 nm step scans using a 2 mm cell over the range of 250–650 nm according to the Snatzke’s method[36]. To form complexes, compound 12 (0.18 mg, 1.33 mM/L) was dissolved in a solution of [Mo6(OAc)12] (0.34 mg, 1.33 mM/L) in DMSO at a 1:1 ratio of the molybdenum complex to the diol.

Measurement of glucose uptake using 2-NBDG in differentiated 3T3-L1 adipocytes. To determine the level of glucose uptake into 3T3-L1 adipocytes, a fluorescent derivative of glucose (2-NBDG) (Invitrogen, OR, USA) was used as previously described with slight modifications[37,38]. First, 3T3-L1 preadipocytes were differentiated by Dulbecco’s Modified Eagle’s Medium (DMEM) (HyClone, IL, USA) containing 10% fetal bovine serum (FBS) (Gibco, NY, USA), 1 μM dexamethasone (Sigma, MO, USA), 520 μM 3-isobutyl-1-methyl-xanthine
Western blot analysis for GLUT4 translocation and expression.  3T3-L1 adipocytes were grown in 6-well plates with DMEM containing 10% FBS (Gibco, NY, USA). The cells were then incubated with the tested compounds for 24 hours or insulin (as a positive control) for 2 hours using serum free media. To evaluate GLUT4 expression in the plasma membrane, the plasma membrane fraction was isolated from the whole cell protein extract as previously described with slight modifications. The clear isolation of the plasma membrane fraction was verified by comparing the expression of β-actin protein by Western blotting in the whole cell lysates and the plasma membrane fractions (Supplementary Fig. S59). The whole cell lysate was lysed using RIPA buffer containing protease and phosphatase inhibitors. Protein concentrations were measured using a BCA protein assay kit (Bio-Rad Laboratories, Inc., CA, USA). Equal amounts of proteins were then electrophoresed on 12% SDS-polyacrylamide gels and then transferred to polyvinylidene fluoride (PVDF) membranes (PVDF 0.45 μm, Immobilon-P, USA). After blocking with 5% skim milk for 1 hour, the membrane was incubated overnight with different primary antibodies for GLUT4 (Santa Cruz, CA, USA), Na+/K+ ATPase α1 (Cell Signaling, MA, USA) or mouse monoclonal β-actin (Thermo Fisher Scientific, Rockford, IL, USA). The membrane was then incubated with HRP-conjugated secondary antibodies for 2 hours at room temperature. The membrane was detected using a LAS 4000 luminescent image analyzer (Fuji Film, Tokyo, Japan).

Western blot analysis of Akt phosphorylation.  3T3-L1 adipocytes were treated with compound 3 for different time points (Supplementary Fig. S60) or test compounds for 2 hours using serum free media. Then, cell lysates were collected using a lysis buffer [50 mM Tris-HCl (pH 7.6), 120 mM NaCl, 1 mM dithiothreitol (DTT), and 1 mM EDTA] with or without test compounds. Western blotting was performed as described above. The membranes were incubated with the primary antibodies for p-Akt (Ser473) and Akt (Cell Signaling, MA, USA) or mouse monoclonal β-actin (Thermo Fisher Scientific, Rockford, IL, USA).

PTP1B inhibition and kinetic assay.  PTP1B enzyme (human, recombinant) was purchased from BIOMOL International LP (USA) and the enzyme assay was performed as previously described. Briefly, the assay was performed in 96-well plate containing 4 mM p-NPP and PTP1B (0.05–0.1 μg) in enzyme buffer [50 mM citrate (pH 6.0), 0.1 M NaCl, 1 mM dithiothreitol (DTT), and 1 mM EDTA] with or without test compounds in triplicate. In addition, an assay was carried out to exclude the fluorescence effect of the test compounds in the absence of PTP1B enzyme. After incubation at 37 °C for 30 minutes, the reaction was terminated with 10 M NaOH solution. The p-nitrophenol product was then measured at 405 nm using an absorbance microplate reader (VersaMaxTM, Randor, PA, USA). The enzyme kinetics were determined using Lineweaver-Burk plots. The PTP1B inhibition mode was examined at different concentrations of the p-NPP substrate (from 1 to 8 mM) in the absence and presence of the test compounds (10, 20 and 40 μM). Half-maximal inhibitory concentration (IC50) values and inhibition type of PTP1B were calculated by Sigma Plot 10.0 (Systat Software Inc., San Jose, CA, USA).

Molecular docking simulation.  Docking studies between the structure of the PTP1B protein and compound 3 were successfully performed using Discovery Studio 4.0/CDOCKER software (Accelrys, San Diego, CA). The PTP1B protein structure was obtained from the Protein Data Bank (http://www.pdb.org) (PDB ID code: 1Q6T). Protein-ligand binding affinities were optimized and calculated according to the CDOCKER interaction energy arising from several interacting bonds, such as conventional hydrogen bonds, carbon-hydrogen bond, π–π T-shaped and π-alkyl interactions.

Statistical analysis.  Data were calculated as the mean ± SD of three independent experiments. The mean value of difference groups was calculated using ANOVA, which was carried out using SPSS Statistics 23 (SPSS, Inc., Chicago, IL, USA). IC50 values and inhibition modes were determined by Sigma Plot 10.0 software (Systat Software Inc., San Jose, CA, USA). Statistically significant p values were established at *p < 0.05, **p < 0.01, and ***p < 0.001.

Data Availability
