Simple Juntas for Shifted Families

Peter Frankl Andrey Kupavskii

Abstract: We say that a family $\mathcal{F}$ of $k$-element sets is a $j$-junta if there is a set $J$ of size $j$ such that, for any $F$, its presence in $\mathcal{F}$ depends on its intersection with $J$ only. Approximating arbitrary families by $j$-juntas with small $j$ is a recent powerful technique in extremal set theory.

The weak point of all known junta approximation results is that they work in the range $n > Ck$, where $C$ is an extremely fast growing function of the input parameters, such as the quality of approximation or the number of families we simultaneously approximate.

We say that a family $\mathcal{F}$ is shifted if for any $F = \{x_1, \ldots, x_k\} \in \mathcal{F}$ and any $G = \{y_1, \ldots, y_k\}$ such that $y_i \leq x_i$, we have $G \in \mathcal{F}$. For many extremal set theory problems, including the Erdős Matching Conjecture, or the Complete $t$-Intersection Theorem, it is sufficient to deal with shifted families only.

In this paper, we present very general approximation by juntas results for shifted families with explicit (and essentially linear) dependency on the input parameters. The results are best possible up to some constant factors. Moreover, they give meaningful statements for almost all range of values of $n$. The proofs are shorter than the proofs of the previous approximation by juntas results and are completely self-contained.

As an application of our junta approximation, we give a nearly-linear bound for the multi-family version of the Erdős Matching Conjecture. More precisely, we prove the following result. Let $n \geq 12sk \log(e^2s)$ and suppose that the families $\mathcal{F}_1, \ldots, \mathcal{F}_s \subset \binom{[n]}{k}$ do not contain $F_1 \in \mathcal{F}_1, \ldots, F_s \in \mathcal{F}_s$ such that $F_i$’s are pairwise disjoint. Then $\min_i |\mathcal{F}_i| \leq \binom{n}{k} - \binom{n-s+1}{k}$.

Key words and phrases: extremal set theory, shifting, juntas

1 Introduction

Let $[n] := \{1, \ldots, n\}$. We use the standard notation $2^{[n]}$ for the power set of $[n]$ and $\binom{[n]}{k}$ for the family of all $k$-element subsets of $[n]$. We say that a family $\mathcal{F} \subset 2^{[n]}$ is a $j$-junta, if there exists a set $J \in \binom{[n]}{j}$ and a
family $\mathcal{F} \subset 2^I$ such that $\mathcal{J} = \{F \subset [n] : F \cap J \in \mathcal{F}^*\}$. We call $J$ as above the center of the junta and $\mathcal{F}^*$ the defining family.

We say that $\mathcal{F} \subset 2^{[n]}$ is $t$-intersecting if $|F_1 \cap F_2| \geq t$ for any two $F_1, F_2 \in \mathcal{F}$. We say “intersecting” instead of “1-intersecting” for shorthand. Similarly, if for any $A \in \mathcal{A} \subset 2^{[n]}$ and $B \in \mathcal{B} \subset 2^{[n]}$, we have $|A \cap B| \geq t$, then we say that $\mathcal{A}$ and $\mathcal{B}$ are cross $t$-intersecting. We say “cross-intersecting” instead of “cross 1-intersecting” for shorthand. In a seminal paper [5], Dinur and Friedgut proved the following theorem, which, informally speaking, states that the structure of large intersecting families is governed by a small number of coordinates.

**Theorem 1** ([5]). There exist functions $j(r), c(r)$ such that for any integers $1 < j(r) < k < n/2$, if $\mathcal{A} \subset \binom{[n]}{k}$ is an intersecting family then there exists an intersecting $j$-junta $\mathcal{J}$ with $j \leq j(r)$ and

$$|\mathcal{F} \setminus \mathcal{J}| \leq c(r) \cdot \binom{n-r}{k-r}.$$ 

This result is, in fact, a corollary of the analogous statement concerning cross-intersecting families.

**Theorem 2** ([5]). There exist functions $j(r), c(r) \geq 1$ such that the following holds. Let $n, a, b \in \mathbb{N}$ with $1 < j(r) < b \leq a$ and $a + b < n$ and let $\mathcal{A} \subset \binom{[n]}{a}$, $\mathcal{B} \subset \binom{[n]}{b}$ be cross-intersecting. Then there exist cross-intersecting $j$-juntas $\mathcal{J}$ and $\mathcal{J}'$ with $j \leq j(r)$, such that

$$|\mathcal{A} \setminus \mathcal{J}| \leq c(r) \cdot \binom{n-r}{a-r} \text{ and } |\mathcal{B} \setminus \mathcal{J}'| \leq c(r) \cdot \binom{n-r}{b-r}.$$ 

Clearly, these results are meaningful only for $n > Ck$ and $n > Ca$, respectively, where $C = C(r)$ is sufficiently large (otherwise, say, in the first result, we may have $C(r)(\binom{n-r}{n-r}) \geq \binom{n}{k}$, in which case the displayed inequality becomes trivial).

Recently, this result was greatly extended by Keller and Lifshitz [19] to the so-called ‘Turan problems for expansions’. This, in particular, includes the case of cross-dependent families. We say that $\mathcal{F}_1, \ldots, \mathcal{F}_s$ are cross-dependent if there is no choice $F_1 \in \mathcal{F}_1, \ldots, F_s \in \mathcal{F}_s$ such that $F_1$ are pairwise disjoint.

**Theorem 3** ([19]). Let $s, r$ be some constants, $k < \frac{n}{3r}$, and consider cross-dependent families $\mathcal{F}_1, \ldots, \mathcal{F}_s \subset \binom{[n]}{k}$. Then there exist $C = C(s, r)$ and cross-dependent $C$-juntas $\mathcal{J}_1, \ldots, \mathcal{J}_s \subset \binom{[n]}{k}$, such that for each $i \in [s]$

$$|\mathcal{F}_i \setminus \mathcal{J}_i| \leq C \cdot \binom{n-r}{k-r}.$$ 

Again, the theorem only makes sense for $n > C'(s, r)k$, and the dependence of $C'$ on $s, r$ is not explicit (and at least exponential in $s, r$). In many cases, it is desirable to have a control of the behaviour of $C'(s, r)$. In particular, this is the case for the Erdős Matching Conjecture (cf. [6], [10], [11]). We also note that, in some related settings, the exponential dependence cannot be improved. This is, e.g., the case of Friedgut’s junta theorem [13].

We say that the family $\mathcal{F}$ is shifted if for any $F = \{x_1, \ldots, x_k\} \in \mathcal{F}$ and any $G = \{y_1, \ldots, y_k\}$ such that $y_i \leq x_i$, we have $G \in \mathcal{F}$. One makes the family shifted by performing shifts (see definition in Section 3.2). We refer to the survey of the first author [9]. Shifting is a very useful combinatorial operation, which
preserves many properties of a family. In particular, it preserves the size of each set and the family. Moreover, it preserves the property of being (cross-) \( t \)-intersecting, cross-dependent etc. Thus, for many extremal problems (including the Erdős Matching Conjecture, Ahlswede–Khachatrian theorem [2] and their common generalization [12]), it is sufficient to restrict oneself to shifted families.

The purpose of this note is to show that one can obtain junta-type results for shifted families with essentially best possible dependencies on the parameters (see the remark after Theorem 10) with purely combinatorial techniques.

In the next section, we illustrate our ideas by giving a simple proof of a stronger version of Theorem 2 for shifted families. In Section 3, we give a general junta approximation-type statement and deduce several of its combinatorial implications, including a stronger version of Theorem 3 for shifted families. In Section 4, we present the proofs of the junta approximation results. In Section 5, we apply these results to obtain the result on the multi-family version of the Erdős Matching Conjecture mentioned in the abstract.

2 Cross \( t \)-intersecting families

Let us first illustrate our methods in the setting of Theorem 2.

**Theorem 4.** Fix integers \( a \geq b \geq r > t > 0 \) and shifted cross \( t \)-intersecting families \( A \subset \left( \begin{array}{c} n \end{array} \right)_a \) and \( B \subset \left( \begin{array}{c} n \end{array} \right)_b \). Put \( j := 2r - t - 1 \). If \( n \geq 2a \) then there exist cross \( t \)-intersecting \( j \)-juntas \( \mathcal{J} \) and \( \mathcal{I} \) with center \( [j] \) such that

\[
|A \setminus \mathcal{J}| \leq 2^j \cdot \left( \frac{n - j}{a - r} \right) \quad \text{and} \quad |B \setminus \mathcal{I}| \leq 2^j \cdot \left( \frac{n - j}{b - r} \right).
\]

(1)

For a family \( \mathcal{F} \subset 2^{[n]} \) and sets \( X \subset S \subset [n] \) we use the following notation:

\[
\mathcal{F}(X,S) := \{ F \setminus X : F \in \mathcal{F}, F \cap S = X \}.
\]

Note that \( \mathcal{F}(X,S) \) is regarded as a subfamily of \( 2^{[n]\setminus S} \).

In the proof of this theorem, we will use the following two lemmas. The first lemma was proved by the first author (cf., e.g., Proposition 9.3 in [9]).

**Lemma 5.** Assume that \( A, B \) are cross \( t \)-intersecting and shifted. Fix \( X, Y, s, \) such that \( X, Y \subset [s] \) and \( |X \cap Y| \leq t - 1 \). Then \( \mathcal{A}(X, [s]) \) and \( \mathcal{B}(Y, [s]) \) are cross \( (t + s - |X| - |Y|) \)-intersecting.

The second lemma was essentially proven in [7]. We give its proof for completeness.

**Lemma 6.** Let \( A' \subset \left( \begin{array}{c} n \end{array} \right)_{a'} \) and \( B' \subset \left( \begin{array}{c} n \end{array} \right)_{b'} \) be cross \( t' \)-intersecting. If \( n' \geq 2 \max \{a', b'\} \) then either \( |A'| \leq \left( \begin{array}{c} n' \end{array} \right)_{a' - r} \) or \( |B'| \leq \left( \begin{array}{c} n' \end{array} \right)_{b' - r} \).

For the sake of completeness, we shall give its proof.

**Proof of Lemma 6.** The proof consists of two propositions. Let us say that a set \( F \subset [n] \) has property \( t' \) if there exists some \( i \geq 0 \) such that

\[
|F \cap [i' + 2i]| \geq t' + i.
\]

\[1\] All previous junta-type theorems rely on results from discrete Fourier analysis.
**Proposition 7** ([7]). The number of sets $F \in \binom{[n]}{k}$, $k \geq t'$, having property $t'$ is $\binom{n}{k-r}$.

**Proof.** Interpret each $k$-element set $F$ as a random walk on $\mathbb{Z}^2$ from point $(0,-t')$ to $(n-k,k-t')$, where at step $i$ we go one up or one right depending on whether the $i$’th element belongs or does not belong to $F$, respectively. Then the sets having property $t'$ are exactly the ones that correspond to random walks that hit the line $x = y$. By reflection principle, the number of such walks is equal to the number of shortest paths from $(-t',0)$ to $(n-k,k-t')$, which is exactly $\binom{n}{k-r}$. \hfill \square

**Proposition 8.** Suppose that the shifted families $\mathcal{A}', \mathcal{B}' \subset 2^{[a]}$ are cross $t'$-intersecting. Then either all $A \in \mathcal{A}'$ have property $t'$ or all $B \in \mathcal{B}'$ have property $t'+1$.

**Proof.** Suppose that $A \in \mathcal{A}'$ does not have property $t'$. Then, by shiftedness, a subset $(1,2,\ldots,t'-1,t'+1,t'+3,t'+5,\ldots)$ is in $\mathcal{A}'$. By the cross $t'$-intersecting property, no subset of $(1,2,\ldots,t',t'+2,t'+4,t'+6,\ldots)$ is in $\mathcal{B}'$. By shiftedness, this implies that $\mathcal{B}'$ has property $t'+1$. \hfill \square

Together, these two propositions imply that either $|\mathcal{A}'| \leq \binom{n}{a-t'}$ or $|\mathcal{B}'| \leq \binom{n}{b-r-1}$.

**Proof of Theorem 4.** Let us put

$$\mathcal{J}^* := \left\{ J \subset [j] : |\mathcal{A}(J,[j])| > \binom{n-j}{a-r} \right\}, \quad \mathcal{J} := \left\{ A \in \binom{[n]}{a} : A \cap [j] \in \mathcal{J}^* \right\};$$

$$\mathcal{J}^* := \left\{ I \subset [j] : |\mathcal{B}(I,[j])| > \binom{n-j}{b-r} \right\}, \quad \mathcal{J} := \left\{ B \in \binom{[n]}{b} : B \cap [j] \in \mathcal{J}^* \right\}.$$

Note that $\mathcal{J}^*$ and $\mathcal{J}^*$ may contain the empty set. We claim that $\mathcal{J}$ and $\mathcal{J}$ are the desired juntas. First, by the definition, it is clear that $|\mathcal{A} \setminus \mathcal{J}| \leq 2^{\binom{n-j}{a-r}}$, and similarly for $\mathcal{B}$ and $\mathcal{J}$.

Second, assume that $\mathcal{J}^*$ and $\mathcal{J}^*$ are not cross $t$-intersecting. This implies that there are two sets $X \in \mathcal{J}^*$ and $Y \in \mathcal{J}^*$ such that $|X \cap Y| \leq t-1$. Denote $x := |X|, y := |Y|$. Consider, the families $\mathcal{A}' := \mathcal{A}(X,[j])$ and $\mathcal{B}' := \mathcal{B}(Y,[j])$. Note that the former family contains $(a-x)$-element sets and the latter contains $(b-y)$-element sets. Due to Lemma 5, $\mathcal{A}'$ and $\mathcal{B}'$ are cross $t'$-intersecting, where $t' = t + j - x - y = 2r - 1 - x - y$.

At the same time,

$$|\mathcal{A}'| > \binom{n-j}{a-r}, \quad (2)$$

$$|\mathcal{B}'| > \binom{n-j}{b-r} \quad (3)$$

by the definition of $\mathcal{J}$, $\mathcal{J}$. In particular, $x, y \leq r - 1$.

Applying Lemma 6 to our situation with $n' := n - j, a' := a - x, b' := b - y, t' := 2r - 1 - x - y$, we get that at least one of the following two inequalities is valid:

$$|\mathcal{A}'| \leq \binom{n-j}{(a-x)-r'}, \quad (4)$$

$$|\mathcal{B}'| \leq \binom{n-j}{(b-x)-t'}. \quad (5)$$
We have \( x, y \leq r - 1 \) and \( j \geq r \), and thus \( (a - x) - t' = a - r - (r - 1 - y) \leq a - r \). Thus, (4) contradicts (2). But, similarly, (5) contradicts (3). Therefore, we conclude that choosing such \( X \) and \( Y \) was impossible in the first place. That is, \( \mathcal{J}^* \) and \( \mathcal{J}^* \), and therefore \( \mathcal{J} \) and \( \mathcal{J} \), are cross \( t \)-intersecting.

One may argue that the constants in (1) are still quite bad. Let us derive the following corollary, showing that, at the expense of slightly worse bounds on \( n \) and \( j \), one can get rid of the constants.

**Corollary 9.** Fix integers \( a \geq b \geq r > t > 0 \) and shifted cross \( t \)-intersecting families \( \mathcal{A} \subset \binom{[n]}{a} \) and \( \mathcal{B} \subset \binom{[n]}{b} \). For any \( \varepsilon > 0 \), put \( j = 2cr - t - 1 \), where \( c := 1 + \left( \frac{2 + \varepsilon}{2\varepsilon} \right)^2 \log e \). If \( n \geq (2 + \varepsilon)a \) then there exists cross \( t \)-intersecting \( j \)-juntas \( \mathcal{J}_1, \mathcal{J}_2 \) with center \( [j] \) such that

\[
|\mathcal{A} \setminus \mathcal{J}_1| \leq \binom{n-r}{a-r} \quad \text{and} \quad |\mathcal{B} \setminus \mathcal{J}_2| \leq \binom{n-r}{b-r}.
\]

**Proof.** Apply Theorem 4 \( \mathcal{A}, \mathcal{B} \) with \( cr \) playing the role of \( r \). Then we get cross \( t \)-intersecting juntas \( \mathcal{J}_1, \mathcal{J}_2 \) with center \( [j] \), satisfying (1). To prove the corollary, it is sufficient to show the second inequality in the following chain of inequalities:

\[
2^j \binom{n - 2cr + t + 1}{k - cr} \leq 2^{2cr} \binom{n - (2c - 1)r}{k - cr} \leq \binom{n-r}{k-r},
\]

where \( k \in \{a, b\} \). We have

\[
\frac{\binom{n - (2c - 1)r}{k - cr}}{\binom{n-r}{k-r}} \leq \left( \frac{k(n - k)}{n^2} \right)^{(c - 1)r} \leq \left( \frac{1 + \varepsilon}{2 + \varepsilon} \right)^{(c - 1)r} = 4^{-(c - 1)r} \left( 1 - \left( \frac{2\varepsilon}{2 + \varepsilon} \right)^2 \right)^{(c - 1)r}
\]

\[
\leq 4^{-(c - 1)r} e^{- (c - 1) \left( \frac{2\varepsilon}{2 + \varepsilon} \right)^2},
\]

where the second inequality in the first line holds due to the bound on \( n \) and the fact that \( x(1 - x) \) is the biggest if \( x \) is as close to 1/2 as possible, and the last inequality holds due to the choice of \( c \).

### 3 The general statement and its implications

In this section, we state a general junta approximation result and then deduce several corollaries for shifted families satisfying different properties. Let us present a geometric interpretation of the property that we are working with.

First, consider the case of one family \( \mathcal{F} \). Imagine that we are given an \( (n + 1) \times (n + 1) \) grid (thought of as a subset of the plane) and we are walking on the grid starting from \((0, 0)\) and at each step we can either go from \((i, j)\) to \((i + 1, j)\) or to \((i + 1, j + 1)\). The steps \( \{i_1, \ldots, i_s\} \) of the walk at which the random walk goes “diagonally” give us a set in \( 2^{[n]} \) and, obviously, there is a one-to-one correspondence between the subsets in \( 2^{[n]} \) and such walks. The walks with exactly \( k \) diagonal steps correspond to \( k \)-element subsets of \([n]\). Thus, any family \( \mathcal{F} \) corresponds to a collection of walks on this grid.
Next, consider the line $\lambda$ defined by $\alpha y = x + q$ for some $\alpha, q > 0$ (here, by $x$ and $y$ we mean the coordinates on the plane). The property that we are interested in is “any walk from $\mathcal{F}$ hits $\lambda$ for some $x$”, where by hitting $\lambda$ we simply mean that $\alpha y \geq x + q$ for the corresponding $(x, y)$.\footnote{Of course, $(x, y)$ is an integer point.}

As was noted long time ago by the first author [7, 8], there is a close relationship between different combinatorial properties of $\mathcal{F}$ and the property that $\mathcal{F}$ hits $\lambda$ for appropriately chosen $\lambda$. Here, we explore this relationship further. Actually, this relationship is the most transparent for the case of several families (i.e., in the “cross setting”).

It is easy to generalize the property of “hitting the line” to the case of several families $\mathcal{F}_1, \ldots, \mathcal{F}_s$. Consider a hyperplane $\pi$ defined by $\sum_{i=1}^{s} \alpha_i y_i = x + q$ for some $\alpha_i, q > 0$. Represent each $F_i \in \mathcal{F}_i$ as a walk in the coordinate plane spanned by $y_i$ and $x$. Then we are interested in the property that the “joint walk (represented by the points $(x, y_1, \ldots, y_s)$) hits the hyperplane $\pi$”.

For example, let us show how the cross $t$-intersecting property is related to “hitting the plane” property. Consider two families $\mathcal{F}_1, \mathcal{F}_2$ and assume that they hit the plane $\pi$ defined by $y_1 + y_2 = x + t$. Then it is easy to see that $\mathcal{F}_1$ and $\mathcal{F}_2$ are cross $t$-intersecting: indeed, for any $F_i \in \mathcal{F}_1$, $F_2 \in \mathcal{F}_2$ find an integer point $p := (x, y_1, y_2)$ such that the joint walk hits the plane $\pi$ at $p$. In terms of sets, it means that $|F_1 \cap \{x\} + |F_2 \cap \{x\}| \geq x + t$, and by pigeon-hole principle, these two sets intersect in at least $t$ elements, even restricted to $\{x\}$. More importantly, if $\mathcal{F}_1$ and $\mathcal{F}_2$ are cross $t$-intersecting and shifted, then they must hit the plane $\pi$ (cf. [9] for the easy proof!)

Finally, let us describe the idea that is behind the junta approximation result below. For some of the lines, as $x$ grows, it gets increasingly more and more unlikely that a random walk (biased random walk, or random walk with fixed number of diagonal steps) hits this line at point $x$. Thus, a bulk of the family must cross the line for small $x$ and stay under it for large $x$. But it is easy to see that this part of the family is an $x$-junta with the same “hitting the line” property. We have a similar situation for several families, i.e., “sums” of random walks “hitting a hyperplane”.

In what follows, all the logarithms have base $e$.

**Theorem 10.** Let $n, s \geq 2$ and $k_1, \ldots, k_s$ be positive integers and $q$ be a non-negative real number. Fix some positive reals $\alpha_1, \ldots, \alpha_s$ and a subset of positive integers $S$. For $i \in [s]$, let $\mathcal{F}_i \subset \binom{[n]}{k_i}$ be such that for any $F_i \in \mathcal{F}_i$, $i \in [s]$, there exists $\ell \in S$ such that

$$\sum_{i=1}^{s} \alpha_i |F_i \cap \ell| \geq \ell + q. \tag{7}$$

Fix a positive real $r = r(s)$. Then there exist juntas $\mathcal{J}_1 \subset \binom{[n]}{k_1}, \ldots, \mathcal{J}_s \subset \binom{[n]}{k_s}$ with center $[j]$ such that for any $F_i \in \mathcal{J}_i$, $i \in [s]$ the inequality (7) holds with some $\ell \in S \cap [j]$ and, moreover,

$$|\mathcal{F}_i \setminus \mathcal{J}_i| \leq \binom{n}{k_i},$$

provided one of the three conditions below holds for some real $\varepsilon \in (0, 1/3]$.

1. We have $j := \max_{i \in [s]} \{ \frac{4\varepsilon}{\alpha_i k_i} (r \log_{1-\varepsilon} k_i + \log \frac{8}{\varepsilon^2}) \alpha_i k_i \}$ and $n \geq (1 - \varepsilon)^{-1} \sigma$, where $\sigma := \sum_{i=1}^{s} \alpha_i k_i$ and $\sigma \geq k_i$ for every $i$.
Theorem 11. (It should be helpful to think of provided one of the three conditions below holds for some real $\alpha$.)

(ii) We have $j := \max_{i \in [s]} \left\{ \frac{4\alpha s}{\varepsilon} \left( r \log \frac{\alpha s}{1 - \varepsilon} + \log \frac{8}{\varepsilon^4} \right) \right\}$ and $n \geq \max_{i \in [s]} (1 - \varepsilon)^{-1} \alpha_i s k_i$.

(iii) For some $C \geq 2$ we have $j := \max_{i \in [s]} \alpha_i s r \log_C (Ce\alpha_i s)$ and $n \geq \max_{i \in [s]} Ce\alpha_i s k_i$.

Remarks.

- Conditions (i) and (ii) in the theorem coincide when $\alpha_k k_1 = \ldots = \alpha_k s$, which is the case in many potential applications.

- We note that, unlike the previous results, our junta approximations work for essentially the full range of $n$. Indeed, one can easily see that in general these problems only make sense for $n \geq \sum_{i \in [s]} \alpha_i k_i$.

- We note that, in general, we can get rid of the log factor in the definition of $j$ by putting $r = C \log^{-1}(\sigma/k_i)$. However, if we want to get an approximation with, say, $|F_i \setminus \bar{b}_i| \leq \left(\frac{n-1}{k_i - 1}\right)$, then cannot remove $\log(\sigma/k_i)$ from Theorem 10 and make both $j$ linear in $s$ and $n$ linear in $sk$. Indeed, consider the problem of approximating one $s$-matching-free family and assume that $j = Csr$ and $n = C'sr$ for some absolute $C$, $C'$. (s is sufficiently large.) Clearly, the best center $J$ of size $j$ to take is $[j]$. Then consider the following $s$-matching-free family $F := \{ F \in \binom{[n]}{s} : |F \cap [2j - 1]| \geq 2Cr \}$. The part of $F$ that is not contained in the junta, has size at least $\left(\frac{j-1}{2Cr}\right) \left(\frac{n-2j-1}{k-2Cr}\right) = \Omega\left(\left(\frac{1}{2}\right)^{2Cr} (\frac{1}{2})^{2Cr-r} \right) \cdot \left(\frac{n-r}{k-r}\right) = \Omega(s') \frac{n-r}{k-r}$, where the $\Omega$-notation depends on $C, C', r$ only. Thus, $F$ is not well-approximated by the junta, provided $s$ is large enough.

For a set $F \subset [n]$, let us define the $p$-biased measure of $F$ by $\mu_p(F) := p^{|F|} (1 - p)^{n - |F|}$. For a family $\mathcal{F} \subset 2^{[n]}$, we put $\mu_p(\mathcal{F}) := \sum_{F \in \mathcal{F}} \mu_p(F)$. We can prove the following $p$-biased non-uniform analogue of Theorem 10. (It should be helpful to think of $p_i$ as $k_i/n$.)

**Theorem 11.** Let $n, s \geq 2$ be positive integers and $q$ be a non-negative real number. Fix some positive real numbers $\alpha_1, \ldots, \alpha_s$ and $p_1, \ldots, p_s \in (0, 1)$. Fix a subset of positive integers $S$. For $i \in [s]$, let $\mathcal{F}_i \subset 2^{[n]}$ be such that for any $F_i \in \mathcal{F}_i$, $i \in [s]$, there exists $\ell \in S$ such that $F_i$ satisfy (7).

Fix a positive real number $r = (s, \varepsilon)$. Then there exist junta $\bar{b}_1, \ldots, \bar{b}_s \subset 2^{[n]}$ with center $[j]$ such that for any $F_i \in \mathcal{F}_i$, $i \in [s]$ the inequality (7) holds with some $\ell \in S \cap [j]$ and, moreover,

$$\mu_{\sigma}(\mathcal{F}_i \setminus \bar{b}_i) \leq p_i^r,$$

provided one of the three conditions below holds for some real $\varepsilon \in (0, 1/3]$.

(i) We have $j := \max_{i \in [s]} \left\{ \frac{\sigma r \log (\frac{\alpha s}{1 - \varepsilon}p_i \log \frac{8}{\varepsilon^4} \right\}$ and $n \geq (1 - \varepsilon)^{-1} \sigma$, where $\sigma := \sum_{i=1}^s \alpha_i p_i$ and $\sigma \geq p_i$ for every $i$.

(ii) We have $j := \max_{i \in [s]} \left\{ \frac{4\alpha s}{\varepsilon} \left( \log \frac{\alpha s}{1 - \varepsilon}p_i + \log \frac{8}{\varepsilon^4} \right) \right\}$ and $n \geq (1 - \varepsilon)^{-1} \alpha_i s p_i$.

(iii) For some $C \geq 2$ we have $j := \max_{i \in [s]} \alpha_i r s \log_C (Ce\alpha_i s)$ and $n \geq \max_{i \in [s]} Ce\alpha_i s p_i$.

The proof of Theorem 11 is almost the same as that of Theorem 10. Moreover, the calculations become easier.
3.1 Combinatorial consequences

The first consequence is for families satisfying a cross-union condition. Note that the case $q = 1$ corresponds to cross-dependence.

**Theorem 12.** Let $s \geq 2$ be an integer and $\varepsilon \in (0, 1/3]$, $r = r(s)$ be positive real numbers. For $i \in [s]$, let $\mathcal{F}_i \subset \binom{[n]}{k}$ be such that $|F_1 \cup \ldots \cup F_s| \leq k_1 + \ldots + k_s - q$ for some integer $q > 0$. Assume that $\mathcal{F}_i$ are shifted. Then there exist juntas $\mathcal{J}_1 \subset \binom{[n]}{k_1}, \ldots, \mathcal{J}_s \subset \binom{[n]}{k_s}$ with center $[j]$ such that for each $i$

$$|\mathcal{F}_i \setminus \mathcal{J}_i| \leq \left( \frac{k_i}{n} \right)^r \left( \frac{n}{k_i} \right)^{r-1},$$

and for any $F_i \in \mathcal{J}_i$, $i \in [s]$, we have $|F_1 \cup \ldots \cup F_s| \leq k_1 + \ldots + k_s - q$, provided one of the following conditions holds.

(i) We have $j := \max_{i \in [s]} \left\{ \frac{4\varepsilon}{k_i} \left( r \log \frac{\sigma}{(1-\varepsilon)k_i} + \log \frac{8}{\varepsilon^2} \right) \right\}$ and $n \geq (1-\varepsilon)^{-1}\sigma$, where $\sigma := \sum_{i=1}^{t} k_i$.

(ii) We have $j := \frac{4\varepsilon}{k_i} \left( r \log \frac{\sigma}{(1-\varepsilon)k_i} + \log \frac{8}{\varepsilon^2} \right)$ and $n \geq \max_{i \in [s]} (1-\varepsilon)^{-1}k_i$.

(iii) For some $C \geq 2$ we have $j := rs \log_C(Cs)$ and $n \geq \max_{i \in [s]} Ces_k$.

Let us derive one particular corollary of this result.

**Corollary 13.** For each $C, s \geq 2$ and $\varepsilon = C^{-\alpha}$, $\alpha > 0$ the following holds. If $n = Cks$, and $\mathcal{F}_1, \ldots, \mathcal{F}_s \subset \binom{[n]}{k}$ are shifted cross-dependent families, then there exist cross-dependent $(2(1+\alpha)s)$-juntas $\mathcal{J}_1, \ldots, \mathcal{J}_s$ on the same center, such that $|\mathcal{F}_i \setminus \mathcal{J}_i| < \varepsilon s^{(n-1)}$ for each $i$.

**Proof.** Apply Theorem 12 (iii) with $k_1 = \ldots = k_s = k$ and $r = \log \frac{n}{k} = \log_C C^{1+\alpha} = \frac{1+\alpha}{\log_C(Cs)}$. Then

$$|\mathcal{F}_i \setminus \mathcal{J}_i| \leq \left( \frac{k}{n} \right)^r \left( \frac{n}{k} \right)^{r-1} = \varepsilon s^{\left( \frac{n-1}{k} \right)}.$$ At the same time, we have

$$j = rs \log_C(Cs) = (1+\alpha)s \frac{\log_C(Cs)}{\log_C(Cs)} < 2(1+\alpha)s,$$

where the last inequality is valid since $Cs > e$.

The validity of Corollary 13 for not necessarily shifted families, but with unspecified dependencies between constants $C, \varepsilon$ and $C'$, where the juntas have center of size $C's$, was announced by Keevash, Lifshitz, Long, and Minzer as a consequence of general sharp threshold-type results (for the latter, see [18]).

**Proof of Theorem 12.** The following proposition is a consequence of the shiftedness of $\mathcal{F}_i$ (see [9]).

**Proposition 14.** For any $F_i \in \mathcal{F}_i, i \in [s]$, there exists $\ell$ such that

$$\sum_{i=1}^{s} |F_1 \cap [\ell]| \geq \ell + q.$$
**Simple Juntas for Shifted Families**

*Idea of the proof.* Assuming the contrary, it is not difficult to find shifts of $F_i$ that would not satisfy $|F_1 \cup \ldots \cup F_s| < k_1 + \ldots + k_s - q$. □

Now we can apply Theorem 10 (in one of the three assumptions on $j, n$) to $\mathcal{F}_i$ with $\alpha_1 = \ldots = \alpha_s = 1$ and $S := [n]$. This gives us the juntas that satisfy (8). However, it is then clear that for any $F_i \in \mathcal{J}_i, i \in [s]$, we have $|F_1 \cup \ldots \cup F_s| \leq k_1 + \ldots + k_s - q$. □

**Theorem 15.** Let $s \geq 2, t \geq 1$ be integers and $\varepsilon \in (0, 1/3]$, $r = r(s)$ be positive real numbers. For $i \in [s]$, let $\mathcal{F}_i \subset \binom{[n]}{k_i}$ be such that $|F_1 \cap \ldots \cap F_s| \geq t$. Moreover, assume that $\mathcal{F}_i$ are shifted. Then there exists juntas $\mathcal{J}_1 \subset \binom{[n]}{k^*_1}, \ldots, \mathcal{J}_s \subset \binom{[n]}{k^*_s}$ with center $[j]$ such that for each $i$

$$|\mathcal{F}_i \setminus \mathcal{J}_i| \leq \left(\frac{k_i}{n}\right)^t \binom{n}{k_i}$$

and such that for any $F_i \in \mathcal{J}_i, i \in [s]$, we have $|F_1 \cap \ldots \cap F_s| \geq t$, provided that one of the following conditions holds.

(i) We have $j := \max_{i \in [s]} \left\{ \frac{4r}{\varepsilon k_i} \left( r \log \frac{\sigma}{(1-\varepsilon)k_i} + \log \frac{\sigma}{\varepsilon k_i} \right), \frac{r}{\varepsilon (s-1)} \right\}$, for $n \geq \left(1 - \varepsilon\right)^{-1} \sigma$, where $\sigma := \sum_{i=1}^s \frac{k_i}{s-1}$.

(ii) We have $j := \max \left\{ \frac{8}{\varepsilon^2} \left( r \log \frac{\sigma}{(s-1)(1-\varepsilon)} + \log \frac{\sigma}{\varepsilon (s-1)} \right), \frac{rs}{\varepsilon (s-1)} \right\}$ and $n \geq \max_{i \in [s]} \left(1 - \varepsilon\right)^{-1} \frac{s}{s-1} k_i$.

(iii) We have $j := 3\varepsilon k$ and $n \geq 2\varepsilon^2 k$.

**Proof.** The proof is very similar to the previous one. Due to shiftedness of $\mathcal{F}_i$, for any $F_i \in \mathcal{F}_i, i \in [r]$, we must have

$$\sum_{i=1}^s \frac{1}{s-1} |F_i \cap [\ell]| \geq \ell + \frac{t}{s-1}.$$  

Then apply Theorem 10 with $q := \frac{1}{s-1}$, $\alpha = \alpha_i := \frac{1}{s-1}$ (and $C = e$ for part (iii)). □

Analogous consequences for non-uniform families can be obtained from the $p$-biased Theorem 11. Since it is straightforward, we leave the details to the reader.

### 3.2 Why do juntas necessarily have center $[j]$?

In this subsection, we prove a simple and intuitive statement that juntas approximating shifted families should have center $[j]$.

For a given pair of indices $1 \leq u < v \leq n$ and a set $A \subset [n]$, define its $(u \leftrightarrow v)$-shift $S_{u \leftrightarrow v}(A)$ as follows. If $u \in A$ or $v \notin A$, then $S_{u \leftrightarrow v}(A) = A$. If $v \in A, u \notin A$, then $S_{u \leftrightarrow v}(A) := (A - \{v\}) \cup \{u\}$. That is, $S_{u \leftrightarrow v}(A)$ is obtained from $A$ by replacing $v$ with $u$. The $(u \leftrightarrow v)$-shift $S_{u \leftrightarrow v}(A)$ of a family $A$ is as follows:

$$S_{u \leftrightarrow v}(A) := \{ S_{u \leftrightarrow v}(A) : A \in \mathcal{A} \} \cup \{ A : A, S_{u \leftrightarrow v}(A) \in \mathcal{A} \}.$$  

**Proposition 16.** Suppose that $\mathcal{F} \subset 2^{[n]}$ is a junta with center $I$ of size $j$ defined by family $\mathcal{J}$. Assume that $\mathcal{F} \subset 2^{[n]}$ is shifted and satisfies $|\mathcal{F} \setminus J| \leq w$. Then, for any $u < v$, the junta $\mathcal{J}$ with center $S_{u \leftrightarrow v}(I)$ and defined by the family $S_{u \leftrightarrow v}(\mathcal{J})$ satisfies $|\mathcal{F} \setminus \mathcal{J}| \leq w$. 

*Discrete Analysis, 2020:14, 18pp.*
To conclude the proof that \( J \) is a \( v \)-shift, the center becomes \( |j| = |I| \). Moreover, if we are shifting several juntas with center \( I \) at the same time, their combinatorial properties are preserved, since the juntas stay the same up to relabeling of the vertices.

**Proof.** It is clearly sufficient to deal with the case \( I \cap \{ u, v \} = v \). Let us construct an injective map \( \phi \) from \( \mathcal{F} \setminus \mathcal{J} \) into \( \mathcal{F} \setminus \mathcal{J} \). If \( F \in \mathcal{F} \setminus \mathcal{J} \) satisfies \( |F \cap \{ u, v \}| \neq 1 \), then \( F \in \mathcal{F} \setminus \mathcal{J} \) as well, and we put \( \phi(F) = F \). If \( |F \cap \{ u, v \}| = 1 \), then \( F \in \mathcal{J} \) if and only if \( F \oplus \{ u, v \} \in \mathcal{J} \). We then put \( \phi(F) = F \oplus \{ u, v \} \) if \( F \oplus \{ u, v \} \in \mathcal{F} \). Due to shiftedness, we are only left to deal with \( F \), such that \( F \cap \{ u, v \} = \{ u \} \) and such that \( F \oplus \{ u, v \} \notin \mathcal{F} \). But if such \( F \) does not belong to \( \mathcal{J} \), then \( F \) does not belong to \( \mathcal{J} \) (because \( S_{u-v}(F) = F \)). Therefore, we can put \( \phi(F) = F \) for such \( F \). \( \square \)

## 4 Proofs of Theorems 10 and 11

### 4.1 Theorem 10

For each \( i \in [s] \), let us put

\[
\mathcal{F}_i := \{ F \in \mathcal{F}_i : |F \cap [\ell]| \geq \ell \cdot \frac{k_i}{\sigma} \text{ for some } \ell > j \}, \quad \mathcal{F}_i' := \mathcal{F}_i \setminus \mathcal{F}_i''.
\]

Let us put

\[
\mathcal{J}_i := \left\{ G \in \binom{[n]}{k_i} : G \cap [j] = F \cap [j] \text{ for some } F \in \mathcal{F}_i'' \right\}.
\]

The following is the key property of sets in \( \mathcal{F}_i'' \).

**Proposition 17.** For any \( F_i'' \in \mathcal{F}_i''' \), \( F_s'' \in \mathcal{F}_s''' \), the property (7) holds for some \( \ell \in S \cap [j] \).

**Proof.** If not, then (7) must hold for some \( \ell > j \) by the hypothesis. But, by definition of \( \mathcal{F}_i'' \), we have \( \alpha_{i|F_i'' \cap [\ell]} < \alpha_i k_i / \sigma \) for any \( F_i'' \in \mathcal{F}_i'' \) and \( \ell > j \), and thus \( \sum_{i=1}^{s} \alpha_i |F_i'' \cap [\ell]| < \ell \leq \ell + q \), a contradiction. \( \square \)

Let us note the following simple facts:

- Each \( \mathcal{J}_i \) is a \( j \)-junta with center in \( [j] \).
- We have \( \mathcal{F}_i'' \subset \mathcal{J}_i \).
- For any \( F_1 \in \mathcal{J}_1, \ldots, F_s \in \mathcal{J}_s \) we have \( \sum_{i=1}^{s} \alpha_i |F_i \cap [\ell]| \geq \ell + q \) for some \( \ell \in S \cap [j] \). Indeed, by Proposition 17 this inequality holds for any \( F_i'' \in \mathcal{F}_i'' \). But, by definition, \( F_i \cap [j] = F_i'' \cap [j] \) for some \( F_i'' \in \mathcal{F}_i'' \).

To conclude the proof that \( \mathcal{J}_i \) are the desired juntas, we are only left to show that

**Proposition 18.** We have \( |\mathcal{J}_i'| \leq \binom{s}{n}^{(k)} n^{(k)} \).
**Proof.** Partition \( F \in \mathcal{S}_1 \) into classes by the maximum value of \( \ell \), for which \(|F \cap [\ell]| \geq k_i \ell / \sigma \). Obviously, \( \ell \) must have the form \( g(t) := \lfloor \sigma t / k_i \rfloor \) for integer \( t \in [k_i / \sigma, k_i] \). Since it does not affect the calculations and simplifies the presentation, in what follows we shall treat \( \sigma t / k_i \) for each \( t \) as an integer (and thus assume that \( g(t) = \sigma t / k_i \)). Thus, we have

\[
|\mathcal{S}_1| \leq \sum_{t = k_i / \sigma}^{k_i} \binom{g(t)}{t} \binom{n - g(t)}{k_i - t} = \sum_{t = k_i / \sigma}^{k_i} h(t, n, k_i, g(t)),
\]

(9)

where \( h(x, n, k, T) = \Pr[X = x] \) for \( X \sim H(n, k, T) \), the hypergeometric distribution \( H(n, k, T) \). Recall that \( H(n, k, T) \) is the distribution of the size of the intersection of a uniformly random \( k \)-element subset of \([n]\) with a fixed set of size \( T \). Take a random variable \( X \sim H(n, k_i, g(t)) \). Then the expectation \( EX \) of \( X \) satisfies \( EX = \frac{g(t)k_i}{n} = \frac{\sigma t}{n} \leq (1 - \varepsilon) t \) due to our choice of \( n \). On the one hand,

\[
h(t, n, k_i, g(t)) \leq \Pr[X \geq t].
\]

(10)

On the other hand, it is known (see, e.g., [16, Theorem 2.10]) that

\[
E e^{uX} \leq E e^{uy}
\]

(11)

for any real \( u \) and \( Y \sim Bin(g(t), k_i / n) \) (note that \( EY = EX \leq (1 - \varepsilon)t \)).

Recall the following Chernoff-type inequality for \( Y' \sim Bin(m, p) \) and \( a > 0 \) (cf., e.g., [3, Theorem A.1.11]):

\[
\Pr[Y' - EY' \geq a] < e^{-\frac{a^2}{2EY'}}.
\]

This inequality is proved using the moment generating function, and thus applies to \( X \) as well due to (11). Recall that \( \varepsilon \leq 1/3 \) and take \( Y' \sim Bin(g(t), p) \), where \( p \geq \frac{k_i}{n} \) is such that \( EY' = (1 - \varepsilon)t \). We get that

\[
\Pr[X \geq t] \leq \Pr[Y \geq t] \leq \Pr[Y' - EY' \geq \varepsilon t] < \exp \left[ -\frac{\varepsilon^2 t}{2(1 - \varepsilon)} + \frac{\varepsilon^3 t}{4(1 - \varepsilon)^2} \right] < \exp \left[ -\frac{\varepsilon^2 t}{4(1 - \varepsilon)} \right] < e^{-\varepsilon^2 t / 4}.
\]

Using the displayed bound above and (10), we get that

\[
\sum_{t = k_i / \sigma}^{k_i} h(t, n, k_i, g(t)) \leq \sum_{t = k_i / \sigma}^{\infty} e^{-\varepsilon^2 t / 4} \leq e^{-\varepsilon^2 k_i / (4\sigma)} \cdot \frac{1}{1 - e^{-\varepsilon^2 / 4}} \leq e^{-\varepsilon^2 k_i / (4\sigma)} \cdot \frac{8}{\varepsilon^2},
\]

where the last bound is due to the fact \( e^{-x} \leq 1 - x / 2 \) for \( x < 1 \). Due to our choice of \( j \), we get that

\[
\sum_{t = k_i / \sigma}^{k_i} f_i \leq e^{-r \log \frac{k_i}{|\mathcal{S}_1|} - \log \frac{8}{\varepsilon^2}} \cdot \frac{8}{\varepsilon^2} = \left( \frac{(1 - \varepsilon)k_i}{\sigma} \right)^r,
\]

and therefore \( \sum_{t = k_i / \sigma}^{k_i} f_i \cdot (n/k_i)^r \leq 1 \) for \( n = (1 - \varepsilon)^{-1} \). As we have already mentioned, this implies that the same inequality holds for \( f_i(n) \) for any \( n \geq (1 - \varepsilon)^{-1} \). Combining everything together, we have

\[
|\mathcal{S}_1|/\binom{n}{\ell} \leq \sum_{t = k_i / \sigma}^{k_i} f_i(n) \leq (k_i/n)^r. \quad \Box
\]

**Discrete Analysis, 2020:14, 18pp.**

11
The second part of Theorem 10 is proven analogously, with the only difference that we define $\mathcal{F}_i', \mathcal{F}_i''$ as follows:

$$\mathcal{F}_i' := \{ F \in \mathcal{F}_i : |F \cap [\ell]| \geq \ell \cdot \frac{\mathcal{S}}{\alpha_i} \text{ for some } \ell > j \}, \quad \mathcal{F}_i'' := \mathcal{F}_i \setminus \mathcal{F}_i',$$

and $g'_i(t) := \alpha_i t$ (again assumed to be integer) plays the role of $g(t)$.

For part (iii) of Theorem 10, we do a slightly different estimate in the proof of Proposition 18. Put $t_0 := j/(\alpha_is)$ and note that $t_0 \geq r \log_C(Ce\alpha_is) = r + r \log(e\alpha_is)$ by our choice of $j$. We have

$$|\mathcal{F}_i'| \leq \sum_{i=t_0+1}^{k_i} \left( \frac{g'_{i}(t)}{t} \right) \left( \frac{n - g'_{i}(t)}{k_i - t} \right). \quad (12)$$

Note that if $g'_i(t) < t$ then the corresponding term in the sum is zero. Thus, in what follows we assume that $g'_i(t) \geq t$. We show that $|\mathcal{F}_i'| \leq \left( \frac{k_i}{n} \right)^r \left( \frac{n}{k_i} \right)^{t-r}$. Indeed,

$$\left( \frac{k_i}{n} \right)^r \left( \frac{n}{k_i} \right)^{t-r} \geq \left( \frac{n}{k_i} \right)^{t-r} \geq \left( Ce\alpha_is \right)^{t-r}. \quad (13)$$

On the other hand,

$$\left( \frac{g'_i(t)}{t} \right) \leq \left( \frac{eg'_i(t)}{r} \right)^{t} \leq \left( e\alpha_is \right)^{t}.$$

Combining the two bounds above, we obtain

$$\frac{|\mathcal{F}_i'|}{\left( \frac{k_i}{n} \right)^r \left( \frac{n}{k_i} \right)^{t-r}} \leq \sum_{i=t_0+1}^{k_i} \left( \frac{e\alpha_is}{{C}^t} \right)^{t-r} \leq \left( \frac{e\alpha_is}{{C}^r} \right)^{t-r} \leq \frac{e\alpha_is}{{C}^r} = 1.$$

### 4.2 Theorem 11

The first part of the proof repeats word for word the proof of Theorem 10, with an obvious replacement of $\left( \frac{n}{k} \right)^r$ by $2^{[n]}$ in the definition of $\mathcal{J}_i$. The only difference is that we need another version of Proposition 17:

Proposition 19. We have $\mu_p(\mathcal{F}_i') \leq p_i'$.

Proof. With the same definition of $g(t)$ (and the same convention concerning omitting integer parts), we get that

$$\mu_p(\mathcal{F}_i') \leq \sum_{i=p_i/\sigma}^{n} \left( \frac{g(t)}{t} \right) p'_i(1 - p_i)^{g(t) - t}.$$

An individual term of this sum is $\Pr[Y = t]$, where $Y \sim Bin(g(t), p_i)$. It is at most $\Pr[Y' - EY' \geq \epsilon t]$, where $Y' \sim Bin(g(t), p)$ and $p \geq p_i$ is chosen so that $EY' = (1 - \epsilon)t$. The remainder of the proof is identical to that of part (i) of Theorem 10.

The proof goes similarly for the second and the third part of the theorem. \qed
5 Families with no cross-matching

As an application of Theorem 12, we prove an exact bound concerning cross-dependent families. The following question was addressed by Aharoni and Howard [1], as well as by Huang, Loh and Sudakov [14]. Given $\mathcal{F}_1, \ldots, \mathcal{F}_s \subset \binom{[n]}{k}$ that are cross-dependent, find $\min_{i \in [s]} |\mathcal{F}_i|$. (We note here that some authors use the term “$\mathcal{F}_1, \ldots, \mathcal{F}_s$ contain a rainbow matching” to refer to the situation, opposite to “cross-dependence”.) In [14], Huang, Loh and Sudakov proved the following result.

**Theorem 20.** If $n > 3sk^2$ and $\mathcal{F}_1, \ldots, \mathcal{F}_s \subset \binom{[n]}{k}$ are cross-dependent then

$$\min_{i \in [s]} |\mathcal{F}_i| \leq \binom{n}{k} - \binom{n-s+1}{k}. \quad (14)$$

Later, a version of this theorem for families with different uniformity was obtained by Lu and Yu [21]. They have also managed to obtain an inequality of the product of sizes of cross-dependent families, partially answering one of the questions of [14]. In [15], Huang, Li and Wang obtained a similar result.

The proof consists of two steps. The first step is to show that the juntas must have the structure of the (conjectured) extremal family. We will need the following lemma proved by Huang, Loh and Sudakov [14].

**Lemma 21.** The statement of Theorem 20 holds for $n \geq 12ks \log(e^2s)$.

**Proof.** Since shifting maintains cross-dependence (cf. [9]), we may assume that $\mathcal{F}_i, i \in [s]$, are shifted. Let us apply Theorem 12 part (iii) with $q = 1, k_1 = \ldots = k_s = k, C = e$ and $r = 3$. We get cross-dependent $j$-juntas $\mathcal{J}_1, \ldots, \mathcal{J}_s$ with $j \geq 3s \log(e^2s)$ and such that $|\mathcal{J}_i \setminus \mathcal{F}_i| \leq \frac{k^3}{n^t} \binom{n}{k}$. In particular, if $\min_{i \in [s]} |\mathcal{F}_i| \geq \binom{n}{k} - \frac{k^3}{n^t} \binom{n}{k}$, then $\min_{i \in [s]} |\mathcal{J}_i| \geq \binom{n}{k} - \frac{k^3}{n^t} \binom{n}{k}$.

The proof consists of two steps. The first step is to show that the juntas must have the structure of the (conjectured) extremal family. We will need the following lemma proved by Huang, Loh and Sudakov [14].

**Lemma 22.** Let $\mathcal{G}_1 \subset \binom{[n]}{k}, \ldots, \mathcal{G}_l \subset \binom{[n]}{k}$ be cross-dependent and $\sum_{i=1}^l t_i \leq |X|$. Then there exists $i$ such that $|\mathcal{G}_i| \leq (l-1) \binom{|X|-1}{t_i-1}$.

Recall that we use the following notation: for any family $\mathcal{G} \subset 2^{[m]}$ and $X \subset Y \subset [m]$, put $\mathcal{G}(X, Y) := \{G \setminus X : G \in \mathcal{G}, G \cap Y = X\}$.

**Lemma 23.** If $\min_{i \in [s]} |\mathcal{J}_i| \geq \binom{n}{k} - \frac{k^3}{n^t} \binom{n}{k}$, then we have $\mathcal{J}_1 = \ldots = \mathcal{J}_s = \{F \in \binom{[n]}{k} : F \cap [s-1] \neq \emptyset\}$.

---

[3] Recall that cross-dependence means that there are no sets $F_1 \in \mathcal{F}_1, \ldots, F_r \in \mathcal{F}_r$ that are pairwise disjoint.
Proof. Consider the defining family $\mathcal{J}_i^*$ of $\mathcal{J}_i$. If $\mathcal{J}_i^*$ contains $l$ singletons for some $l \in [s-1]$, then these singletons must be $1, \ldots, l$ due to shiftedness. Clearly, if each $\mathcal{J}_i^*$ contain $s-1$ singletons, then they cannot contain any sets disjoint to $[s-1]$, and the claim is proved.

W.l.o.g., assume that $\mathcal{J}_i^*$ does not contain $\{s-1\}$. Consider a bipartite graph $G$ between $\{1, \ldots, s-1\}$ and $\mathcal{J}_1^*, \ldots, \mathcal{J}_s^*$, where an edge between a singleton and a family is drawn if and only if the singleton belongs to the family. Take a maximal (non-extendable) matching in this graph, such that the singletons cover the initial segment $[s-l]$, where $l \geq 1$ is an integer. W.l.o.g., assume the families that are not matched are $\mathcal{J}_1^*, \ldots, \mathcal{J}_s^*$ (note that $\mathcal{J}_1^*$ is not matched since it was not included in the graph). Consider the families $\mathcal{J}_i^* := \mathcal{J}_i^* \setminus \mathcal{J}_i(\emptyset, [s-l])$ and $\mathcal{J}_i := \mathcal{J}_i(\emptyset, [s-l])$, $i = 1, \ldots, l$. The former are the families on $2^k$ for $X := [s-l+1, j]$ and none of these families contain a singleton due to the maximality of the chosen matching.

If $l = 1$ then $\mathcal{J}_1^*(\emptyset, [s-2])$ can only contain sets containing $s-1$ (otherwise, $\mathcal{J}_1, \ldots, \mathcal{J}_s$ are not cross-dependent). Thus $|\mathcal{J}_1| \leq \binom{n}{k} - \binom{n-s+1}{k} - \binom{n-l}{k} < \binom{n}{k} - \binom{n-s+1}{k} - \frac{k^3}{n^3} \binom{n}{k}$, where the last inequality is valid for $n > 2jk$.

From now on, we assume that $l \geq 2$. Our next goal is to prove that

one of $\mathcal{J}_1, \ldots, \mathcal{J}_l$ has size smaller than $\left( n - s + l \right) - \left( n - s + 1 \right) - \frac{k^3}{n^3} \binom{n}{k}$, \hspace{1cm} (15)

Since $|\mathcal{J}_i \setminus \mathcal{J}_i| \leq \binom{n}{k} - \binom{n-s+1}{k}$, this and $|\mathcal{J}_i| = |\mathcal{J}_i \setminus \mathcal{J}_i| + |\mathcal{J}_i|$ would lead to a contradiction.

For each $t = 2, \ldots, k$, consider

$\mathcal{J}_i^{(t)} := \mathcal{J}_i \cap X_t$.

The families $\mathcal{J}_1^{(t_1)}, \ldots, \mathcal{J}_l^{(t_l)}$ are cross-dependent for any $t_1, \ldots, t_l$. The following claim is crucial in bounding the size of $\mathcal{J}_i$.

Claim 24. For any $\beta_2, \ldots, \beta_k \geq 0$, there is $i$ such that $\sum_{t=2}^{k} \beta_t |\mathcal{J}_i^{(t)}| \leq \sum_{t=2}^{k} \beta_t |\mathcal{J}_i^{(j-1)}|$.

Proof. Assume that this does not hold. Then, for each $i \in [l]$, there is $t_i$ such that $|\mathcal{J}_i^{(t_i)}| \geq l \binom{j-1}{t_i-1} > l \binom{|X_{t_i}|-1}{t_i-1}$.

Since $\mathcal{J}_i^{(t_i)} \subset \binom{X_{t_i}}{t_i}$, we have $|\mathcal{J}_i^{(t_i)}| \leq \binom{|X_{t_i}|}{t_i}$. Together, these two inequalities imply $t_i \leq |X|/l$ and thus $\sum_{i=1}^{l} t_i \leq |X|$. Applying Lemma 22, we get a contradiction with the fact that $\mathcal{J}_1^{(t_1)}, \ldots, \mathcal{J}_l^{(t_l)}$ are cross-dependent.

Let us put $\beta_i := \binom{n-j}{k-i}$ for every $t = 2, \ldots, k$ and apply the claim. Then there is $i \in [l]$, such that

$\sum_{t=2}^{k} \binom{n-j}{k-t} |\mathcal{J}_i^{(t)}| \leq \sum_{t=2}^{k} \binom{n-j}{k-t} l \binom{j-1}{t-1}$.

The left hand side of (16) is exactly $|\mathcal{J}_i|$! Finally, we are left to estimate the right hand side of (16). Denote the $t$-th term of the summation by $f(t)$. Recall that $n \geq 4jk$, and, due to $k \geq 2$ and $j \geq 2$, we have $n - j - k \geq 3jk$. We have

$$\frac{f(t)}{f(t+1)} = \frac{n-j-k+t+1}{k-t} \cdot \frac{t}{j-t} > 3t \geq 3.$$
Thus, we get that (16) and the inequality above implies $|S_i| \leq \sum_{t=2}^{k} f(t) < f(1) \cdot \sum_{t=1}^{k} (1/3)^t = f(1) \cdot 1^{1/3} = \frac{1}{2} f(1) = \frac{1}{2} \binom{n-1}{k-1}$. On the other hand, $(\binom{n-s+1}{k} - \binom{n-1}{k} - \frac{k^3}{n^3} \binom{n}{k}) \geq (l - 1) \binom{n-1}{k-1}$. Since $l \geq 2$, the last expression is an upper bound on $|S_i|$, which concludes the proof of (15).

The second step is to show that the families $F_i$ must satisfy $\mathcal{A}_i \setminus F_i = \emptyset$ for each $i \in [s]$. This part of the argument is similar to the proofs from [5, 19].

Assume that, among $i \in [s]$, the density $\alpha_i := F_i(\emptyset, [s-1])/\binom{n-s+1}{k}$ is the largest for $i = 1$ and put $\beta_i := F_i([i], [s-1])/\binom{n-s+1}{k}$ for each $i = 2, \ldots, s, t \in [s-1]$. For a family $\mathcal{G} \subset \binom{[n]}{k}$ and $t \geq k$, let $\mathcal{A}_t^{\mathcal{G}}$ be the collection of all sets in $\binom{[n]}{k}$ that contain at least one set from $\mathcal{G}$. The following analytic corollary of the Kruskal–Katona theorem was proved by Bollobás and Thomason [4]:

$$|\mathcal{A}_t^{\mathcal{G}}/\binom{n}{k}|^{n-k} \geq \mathcal{G}/\binom{n}{k}|^{n-t}.$$

From here, we conclude that $\alpha_i' := |\mathcal{A}_{(n+k)/2}^{\mathcal{F}_i}(\emptyset, [s-1])| \geq \alpha_i^{1/2}$.

At the same time, for any bijection $\pi : [s-1] \to [2, s]$, the families $\mathcal{F}_{\pi(i)}([i], [s-1])$, $i \in [s-1]$, and $\mathcal{A}_{(n+k)/2}^{\mathcal{F}_1}(\emptyset, [s-1])$ are cross-dependent. Since $(n+k)/2 + (s-1)k < n$, we may take a random ordered matching consisting of $s-1$ sets $M_1, \ldots, M_{s-1}$ of size $k$ and one set $M_s$ of size $(n+k)/2$. In any such matching, there are at most $s-1$ indices $i \in [s]$ such that: $M_i \in \mathcal{F}_{\pi(i)}([i], [s-1])$ for $i \in [s-1]$, or $M_i \in \mathcal{A}_{(n+k)/2}^{\mathcal{F}_1}(\emptyset, [s-1])$ for $i = s$. Computing the expectation of the number of such indices, we get

$$\alpha_i' + \sum_{i=1}^{s-1} \beta_i' \leq s - 1.$$

Therefore, there exists $i \in [2, s]$, such that $\sum_{i=1}^{s-1} \beta_i' \leq s - 1 - \alpha_i'$. This implies that

$$|F_i| \leq \binom{n}{k} - \binom{n-s+1}{k} + \frac{k^3}{n^3} \binom{n}{k} - \frac{k^3}{n^3} \binom{n-s+1}{k-1} < \binom{n}{k} - \binom{n-s+1}{k},$$

a contradiction. Here the last inequality is again due to our choice of $n$, that is, $n > 12ks\log(e^2s)$.

Thanks to the Kruskal–Katona theorem, we can derive the following non-uniform generalization of Theorem 21.

**Theorem 25.** Fix integers $k_1, \ldots, k_s$ and assume that $n \geq 12ks\log(e^2s)$ for $k := \max_{i\in[s]} k_i$. Assume that $F_1 \subset \binom{[n]}{k_1}, \ldots, F_s \subset \binom{[n]}{k_s}$ are cross-dependent. Then there exists $i \in [s]$ such that

$$|F_i| \leq \binom{n}{k_i} - \binom{n-s+1}{k_i}.$$

**Proof.** Suppose that $|F_i| > \binom{n}{k_i} - \binom{n-s+1}{k_i}$ for every $i$. Then the families $\mathcal{A}^k_{F_1}, \ldots, \mathcal{A}^k_{F_s}$ are cross-dependent as well. Moreover, we claim that

$$|\mathcal{A}^k_{F_i}| > \binom{n}{k} - \binom{n-s+1}{k}.$$
for every $i \in [s]$. This would contradict Theorem 21, so we only need to verify the displayed inequality.

Set $G_i := \{ [n] \setminus F : F \in \mathcal{F}_i \}$.

$$|G_i| > \left( \frac{n-1}{k_i-1} \right) + \ldots + \left( \frac{n-s+1}{k_i-1} \right) = \left( \frac{n-1}{n-k_i} \right) + \ldots + \left( \frac{n-s+1}{n-k_i-s+1} \right).$$

By the Kruskal–Katona theorem [20, 17], its shadow on level $n-k$ will be

$$|\partial^{n-k} G_i| > \left( \frac{n-1}{n-k} \right) + \ldots + \left( \frac{n-s+1}{n-k-s+1} \right) = \left( \frac{n}{k} \right) - \left( \frac{n-s+1}{k} \right).$$

But $|\partial^{n-k} G_i| = |\tilde{\mathcal{F}}_i|$. \hfill \qed

### 6 Concluding Remarks

We believe that Theorem 21 is only one example of the many possible scenarios where the shifted juntas enable one to get better, concrete bounds which seem to be elusive for the general juntas obtained by means of discrete Fourier transform methods.

We note that the validity of Theorem 21 for $n > C s_k$ with some large $C$ was announced by Keevash, Lifshitz, Long, and Minzer as a consequence of general sharp threshold-type results. In the proof, they use the aforementioned variant of Corollary 13.

### Acknowledgments

We thank Noam Lifshitz and the anonymous referee for many helpful remarks.
