Emerging Roles of RNA-Binding Proteins in Plant Growth, Development, and Stress Responses

Kwanuk Lee, and Hunseung Kang*

Posttranscriptional regulation of RNA metabolism, including RNA processing, intron splicing, editing, RNA export, and decay, is increasingly regarded as an essential step for fine-tuning the regulation of gene expression in eukaryotes. RNA-binding proteins (RBPs) are central regulatory factors controlling posttranscriptional RNA metabolism during plant growth, development, and stress responses. Although functional roles of diverse RBPs in living organisms have been determined during the last decades, our understanding of the functional roles of RBPs in plants is lagging far behind our understanding of those in other organisms, including animals, bacteria, and viruses. However, recent functional analysis of multiple RBP family members involved in plant RNA metabolism and elucidation of the mechanistic roles of RBPs shed light on the cellular roles of diverse RBPs in growth, development, and stress responses of plants. In this review, we will discuss recent studies demonstrating the emerging roles of multiple RBP family members that play essential roles in RNA metabolism during plant growth, development, and stress responses.

INTRODUCTION

Gene expression in living organisms is commonly regulated at both transcriptional and posttranscriptional levels, which is crucial for the growth and development as well as the response and adaptation of the organisms to diverse environmental stimuli (Floris et al., 2009; Simpson and Filipowicz, 1996). Posttranscriptional regulation of gene expression includes RNA processing, pre-mRNA splicing, and RNA export and decay, which is referred to as RNA metabolism and is central for various cellular processes in eukaryotes (Simpson and Filipowicz, 1996). The regulation of RNA metabolism is carried out by either direct or indirect binding of RNA-binding proteins (RBPs) to target RNAs. Determination of protein structures and functional characterization of RBPs in diverse organisms have revealed that RBPs harbor several conserved motifs and domains, including RNA-recognition motif (RRM), zinc finger motif, K homology (KH) domain, glycine-rich region, arginine-rich region, RD-repeats, and SR-repeats (Alba and Pages, 1998; Lorković and Barta, 2002). Plant genomes encode a variety of RBPs, which suggests the functional diversity of RBPs in plant growth, development, and stress responses (Lorković, 2009; Mangeon et al., 2010). In particular, those RBPs harboring an RRM at the N-terminus and a glycine-rich region at the C-terminus, thus referred to as glycine-rich RBP (GRP), zinc finger-containing GRP (RZ), cold shock domain protein (CSDP), and RNA helicase (RH) have been implicated to play crucial roles in plant growth and stress responses (Jankowsky, 2011; Jung et al., 2013; Mihailovich et al., 2010). Importantly, many nuclear-encoded chloroplast- or mitochondria-targeted RBPs play pivotal roles in RNA metabolism in chloroplasts and mitochondria (Hammani and Giege, 2014; de Longevialle et al., 2010; Stern et al., 2010). Several recent studies have demonstrated that chloroplast-targeted proteins, including Rh, chloroplast RNA splicing and ribosome maturation protein (CRM), S1 RNA-binding domain protein (SDP), and pentatricopeptide repeat protein (PPR) participate in rRNA processing or intron splicing under normal and stress conditions (Gu et al., 2014; 2015; Han et al., 2015; Lee et al., 2014). Moreover, plant-specific PPRs are mainly targeted to chloroplasts or mitochondria and are involved in organellar RNA metabolism (Barkan and Small, 2014; Brown et al., 2014; de Longevialle et al., 2010; Schmitz-Linneweber and Small, 2008). In this review, we will focus on several RBP families, including GRP, RZ, CSDP, RH, CRM, SDP, and PPR, which play crucial roles in plant growth, development, and stress responses.

STRUCTURAL FEATURES OF RBPS

RRM is the best-characterized RNA-binding motif found in all eukaryotes, and many RBPs possess one or two RRMs at the N-terminal region (Alba and Pages, 1998; Lorković and Barta, 2002). Typical RBPs contain auxiliary domains or motifs at the C-terminal region, including glycine-rich region, zinc finger motif, arginine-rich domain, RD-repeats, and SR-repeats, which determine the binding specificity of RBPs to target RNAs (Nagai et al., 1995). Among those RBPs, GRPs are well-characterized in plants, and the genomes of Arabidopsis thaliana and rice (Oryza sativa) harbor eight and six GRP genes, respectively (Lorković and Barta, 2002). GRPs contain a canonical RRM at the N-terminus and a glycine-rich region at the C-terminus (Fig. 1). GRPs harboring an additional CCHC-type zinc finger in the glycine-rich region, referred to...
RNA-Binding Protein in Plant Development and Stress Response
Kwanuk Lee & Hunseung Kang

as RZs, have been found in Arabidopsis and rice (Kim et al., 2010a; 2010b; Mangeon et al., 2010). The genomes of Arabidopsis and rice harbor three R2 genes, and AtRZs and OsRZs share approximately 40% of amino acid sequence similarity as well as the well-conserved CCHC-type zinc finger motif (Fig. 1).

Cold shock domain (CSD) is found in Y-box proteins in eukaryotes and has the ability to bind RNA, single-stranded DNA, and double-stranded DNA (Graumann and Marahiel, 1998; Manival et al., 2001). Contrary to bacterial cold shock protein (CSP) that contains only the CSD, typical plant CSDPs harbor a C-terminal glycine-rich region interspersed with several CCHC-type zinc fingers, in addition to CSD at the N-terminus (Chai kam and Karlson, 2008; Karlson and Imai, 2003; Karlson et al., 2002) (Fig. 1). Four genes encoding CSDPs have been identified in Arabidopsis and rice genomes (Karlson and Imai, 2003). RHs are classified into six superfamilies (SF1-SF6), and each RH has well-defined nine motifs (Q, I, Ia, Ib, II, III, IV, V, and VI) (Fig. 1). Among the RHs, DEAD-box RHs are the largest family in SF2 helicases that possess the conserved Q motif and helicase activity. The Arabidopsis and rice genomes encode approximately 58 and 50 DEAD-box RHs, respectively (Mingam et al., 2004).

CRM proteins were first investigated in prokaryotes, such as archaea and bacteria, and are divided into four subfamilies, depending on their sequence similarity and domain structures (Barkan et al., 2007). CRM domains are orthologous to the bacterial YhbY and are similar to KH RNA-binding domain (Chekanova et al., 2002; Jeon et al., 2012; Schein et al., 2008). PPR proteins consist of tandem repeats of 35-amino acid motifs that fold into one pair of antiparallel β helices (Schmitz-Linneweber and Small, 2008, Small and Peeters, 2008; Yin et al., 2013) (Fig. 1). Importantly, PPR proteins are abundant in land plants and mainly localized in organelles such as chloroplasts or mitochondria (de Longevialle et al., 2010; Lurin et al., 2004; O’Toole et al., 2008; Saha et al., 2007). Plant PPR proteins are divided into two major superfamilies of P- and PLS-classes (P motif: 35 amino acids, L motif: 36 amino acids, and S motif: 31 amino acids) and are involved in RNA metabolism via recognizing specific sequences of RNA substrates (Bar kan and Small, 2014; Filipovska and Rackham, 2012; Schmitz-Linneweber and Small, 2008). Proteome analysis revealed that the Arabidopsis and rice genomes encode more than 450 and 650 PPR proteins, respectively, whereas prokaryotes and humans have less than 7 PPR proteins (Lighthowers and Chrzanowska-Lighthowers, 2008; Rackham and Filipovska, 2012).

**Fig. 1.** Schematic presentation of domain structures of RNA-binding proteins. Glycine-rich RNA-binding protein (GRP) harbors an RNA-recognition motif (RRM) at the N-terminal half and a glycine-rich region at the C-terminal half. R2 protein contains an RRM and a glycine-rich region interspersed with a CCHC-type zinc finger motif. Cold shock domain protein (CSDP) harbors an N-terminal cold shock domain (CSD) and a C-terminal glycine-rich region interspersed with a CCHC-type zinc finger motif. DEAD-box RNA helicase (RH) consists of Q, I, II (DEAD), III, IV, V and VI domains. Chloroplast RNA splicing and ribosome matur ation domain (CRM) protein contains a highly conserved GxxG sequence, and S1 domain containing-protein (SDP) harbors S1 RNA-binding domain. Pentatricopeptide repeat protein (PPR) protein contains tandem repeats of 35-amino acid motifs.

**ROLES OF RBPS IN PLANT GROWTH AND DEVELOPMENT**

Recent years have seen an increase in the assessment of the functional roles of RBPs related to the regulation of flowering time and floral organ formation (Figure 2). FCA and FPA harboring two RRMs enhance flowering by preventing the expression of floral repressor FLOWERING LOCUS C (FLC) (Macknight et al., 1997; Lim et al., 2004). AtGRP7 and KH domain proteins such as PEPPER and FLOWERING LOCUS K promote flowering by inhibiting FLC expression (Lim et al., 2004; Mockler et al., 2004; Ripoll et al., 2006). It was demonstrated that AtGRP2 is involved in seed and flower development (Fusaro et al., 2007). In addition, RH SWA3 is necessary for embryogenesis or embryo development in Arabidopsis (Liu et al., 2010a; Tripurani et al., 2011). Recently, the importance of RBPs in intron splicing and plant growth and development has been demonstrated. Among the seven minor splicingosomal small nuclear ribonucleoproteins that are involved in splicing of U12-type introns, U11/ U12-31K and U11/U12-65K proteins play essential roles in the splicing of many U12 introns, which is crucial for normal growth and development of dicot and monocot plants (Jung and Kang, 2014; Kim et al., 2010c; Kwak et al., 2012).
Gene expression in chloroplasts and mitochondria is mainly regulated at posttranscriptional levels such as intron splicing, RNA editing, and RNA degradation, which is crucial for the biogenesis and function of chloroplasts and mitochondria (del Campo, 2008; Stern et al., 2010). Many recent studies have demonstrated that a variety of nuclear-encoded RBPs are targeted to chloroplasts or mitochondria and play indispensable roles during RNA metabolism in these cellular organelles (del Campo, 2009; Stern et al., 2010). The chloroplast-targeted DEAD-box RHs, AtRH3, AtRH22, and AtRH36, and the mitochondria-targeted RH, PMH2, are associated with the splicing of group II introns and rRNA processing, which affects chloroplast or mitochondria biogenesis during the normal growth and development of plants (Asakura et al., 2012; Chi et al., 2012; Gu et al., 2014; Huang et al., 2010; Kanai et al., 2013; Kohler et al., 2010) (Fig. 2). RBPs harboring CRM domains, including Arabidopsis AtCRS1, AtCAF1, AtCAF2, AtCFM2, AtCFM3, and AtCFM4, are involved in the splicing of specific introns as well as the processing of 16S and 23S RNAs (Asakura and Barkan, 2006; 2007) (Fig. 2). These results clearly demonstrate that CRM proteins play crucial roles in intron splicing, which is essential for normal growth and development of plants.

**Fig. 2.** Cellular functions of diverse RNA-binding proteins involved in RNA metabolism during growth, development, and stress response of plants. A variety of RNA-binding proteins (RBPs) play essential roles in RNA processing and pre-mRNA splicing in the nucleus, RNA export, mRNA degradation, and translational control in the cytoplasm. Moreover, diverse nuclear-encoded RBPs are targeted to mitochondria or chloroplasts and play indispensable roles in mitochondrial or chloroplasts RNA metabolism, which is crucial for organelar biogenesis and function. Examples of RBPs whose functions in each cellular process have been experimentally determined are shown in parenthesis. Abbreviations such as CRM, GRP, PPR, RZ, RH, and SDP are described in Fig. 1.

**DIVERSE ROLES OF RBPS IN ABIOTIC STRESS RESPONSES**

The involvement of RBPs in the response of plants to different environmental cues has been consistently demonstrated in diverse plant species (Lorkovic, 2009; Mangeon et al., 2010; Sachetto-Martins, 2000). In particular, the stress-responsive expression and functional roles of RBPs, including GRPs, RZs, CSDPs, RHs, CRMs, SDPs, and PPRs, have been extensively investigated in Arabidopsis, rice, wheat (*Triticum aestivum*), barely (*Hordeum vulgare*), and cabbage (*Brassica rapa*) under diverse environmental conditions (Fig. 2). Arabidopsis AtGRP2 and AtGRP7 and rice OsGRP1 and OsGRP4 promote seed germination and seedling growth under low temperatures and confer freezing tolerance to Arabidopsis plants (Kim et al., 2007a; 2008a; 2010a; Kwak et al., 2005). Interestingly, among the three RZ family members present in the Arabidopsis, rice, and wheat genomes, only AtRZ-1a, OsRZ2, and TaRZ2 affect seed germination and seedling growth at low and freezing temperatures (Kim and Kang, 2006; Kim et al., 2005; 2010b; Xu et al., 2014). These studies demonstrate that certain family members of GRPs and RZs play important roles in plant response to abiotic stresses.

Plant CSDPs are highly induced in plants upon stress treatment, especially by cold stress treatment. The Arabidopsis and rice genomes harbor four genes encoding CSDPs with different number of CCHC-type zinc fingers (Karstorn and Imai, 2003; Karlson et al., 2002). Among the four CSDPs found in Arabidopsis, AICSDP2 and AICSDP3 confer freezing tolerance to Arabidopsis plants (Kim et al., 2007a; 2008a; 2010a; Kwak et al., 2005). Interestingly, among the three RZ family members present in the Arabidopsis, rice, and wheat genomes, only AtRZ-1a, OsRZ2, and TaRZ2 affect seed germination and seedling growth at low and freezing temperatures (Kim and Kang, 2006; Kim et al., 2005; 2010b; Xu et al., 2014). These studies demonstrate that certain family members of GRPs and RZs play important roles in plant response to abiotic stresses.

DEAD-box RHs can catalyze the unwinding of the secondary structures in RNA molecules and thereby affect RNA metabo-
RNA-Binding Protein in Plant Development and Stress Response
Kwanuk Lee & Hunseung Kang

Contrary to the increasing understanding of the importance and emerging roles of RBPs in plant growth, development, and stress responses, the mechanistic roles of RBPs in these cellular processes are largely unknown. However, several recent studies point to the cellular roles of RBPs as RNA chaperones in plant growth, development, and stress responses. During RNA metabolism, RNA molecules need to be correctly folded into non-functional structures due to their intrinsic kinetic and thermodynamic folding problems (Herschlag, 1995; Woodson, 2010). Both RNA chaperones and specific RBPs can help RNAs to achieve their active functional states (Rajkowitsch et al., 2007). RNA chaperones are nonspecific RBPs that facilitate RNA folding via structural rearrangement of misfolded RNAs (Rajkowitsch et al., 2007; Woodson, 2010). Compared to specific RBPs that bind to specific target RNAs, RNA chaperones generally bind to various RNA substrates with low sequence specificity (Ivanyi-Nagy et al., 2005).

Recent studies have demonstrated that RNA chaperones play crucial roles in the growth and development of living organisms, including bacteria, viruses, animals, and plants (Kang et al., 2013). Some examples of RNA chaperones include viral nucleocapsid protein, long interspersed element-1 in animals, and several bacterial proteins such as Hfq, FinO, and Prop (Arthur et al., 2003; Chambers and Bender, 2011; Chaulk et al., 2011; Martin, 2010). In addition, many E. coli DEAD-box RHs, including DeaD, RhiB, RHE, and SmR5p, and yeast Ms116p function as an RNA chaperone in the splicing of mitochondrial group I and II introns (Huang et al., 2005; Mohr et al., 2002; 2006). Interestingly, U11/U12-31K, the minor spliceosomal protein, harbors RNA chaperone activity and plays an essential role in the splicing of U12-type introns (Kim et al., 2010; Kwak et al., 2012). Several recent findings have demonstrated that chloroplast-targeted proteins such as CFM4, RH3, SDP, and SRRP1 possess RNA chaperone activity and affect rRNA processing and intron splicing in chloroplasts (Gu et al., 2014, 2015; Han et al., 2015; Lee et al., 2014). These studies clearly indicate that many RBPs harboring RNA chaperone activity play essential roles in the regulation of RNA metabolism during plant growth and development.

Involvement of RBPs with RNA chaperone activity in plant stress responses has been extensively investigated in diverse plant species. It has been determined that Arabidopsis AtCSDP1 and AtCSDP3, cabbage BrCSDP3, wheat CSDPs, and rice CSDPs harbor RNA chaperone ability, which is important for stress response and cold adaptation process in plants (Chaiakam and Karlsson, 2008; Choi et al., 2015; Kim et al., 2007a, 2009). In addition, many GRP and RZ family members, including Arabidopsis AtGRP2 and AtGRP7, rice OsGRP1, OsGRP4 and OsGRP6, Arabidopsis AtrZ-1a, rice OsR2Z, and wheat TaR2Z, possess RNA chaperone activity during stress responses (Kim et al., 2005; 2005b; 2008a; 2010a; Xue et al., 2013). Although the functional roles of many RHs in plant stress responses have been demonstrated, the RNA chaperone activity of only AtrRH25 was determined in Arabidopsis under freeze stress conditions (Kim et al., 2008b). Considering that PPR proteins are widely present in land plants and are involved in chloroplast or mitochondrial RNA metabolism under normal and stress conditions, it would be interesting to determine whether any PPR proteins display RNA chaperone function in plants under diverse environmental stimuli.

CONCLUSION

Although studies on the functional roles of RBPs in growth, development, and stress response of plants are rapidly increasing in recent years, our understanding of the cellular roles of RBPs during RNA metabolism in plants is far from sufficient. Considering that a variety of RBPs are targeted to chloroplasts and/or mitochondria, it would be of interest to determine the functional roles of these RBPs in organelar RNA metabolism during plant growth and development as well as plant stress responses. In particular, investigation of the RNA chaperone
activity of RBPs will provide clues about the cellular roles and action mechanism of RBPs during RNA metabolism in organelle biogenesis, plant development, and stress responses. As recent development of RNA-seq allows us to investigate the genome-wide analysis of RNAs in an organism, it would be of great interest to determine the fates and processing of RNAs in the mutants of particular RBPs involved in plant growth and stress responses. A major task for the future is to identify RNA targets and to understand how RBPs recognize substrate RNAs and how RBPs interact with other protein factors to regulate posttranscriptional RNA metabolism during plant growth and development under normal as well as stressful conditions.
