Abstract
In this paper, we present a generic semi-supervised Word Sense Disambiguation (WSD) method. Currently, the existing WSD methods extensively use domain resources and linguistic knowledge. Our proposed method extracts context based lists from a small sense-tagged and untagged training data without using domain knowledge. Experiments on Hindi and Marathi Tourism and Health domains show that it gives good performance without using any language specific linguistic information except the sense IDs present in the sense-tagged training set and works well even with small training data by handling the data sparsity issue. Other advantages are that domain expertise is not needed for crafting and selecting features to build the WSD model and it can handle the problem of non availability of matching contexts in sense-tagged training set. It also finds sense IDs of those test words which are not present in sense-tagged training set but their associated sense IDs are present. This feature can help human annotators while preparing sense-tagged corpus for a language by suggesting them probable senses of unknown words. These properties make the method generic and especially suitable for resource-poor languages and it can be used for various languages without requiring a large sense-tagged corpus.

1 Introduction
Word Sense Disambiguation (WSD) is considered as one of the most challenging Natural Language Processing (NLP) task and is described as an AI-complete problem (Navigli, 2009; Mallery, 1988). This is a classification task which involves determining the correct meaning of each word in a sentence/phrase based on the neighboring context words. Humans are very good at judging meaning of words in different contexts but when it comes to automate this task, it becomes very tough. Design of automated WSD methods, both supervised and unsupervised, requires the intuitive knowledge transfer from humans to WSD algorithms via knowledge structures like WordNet (Fellbaum, 1998; Banerjee and Pedersen, 2002), machine readable dictionaries (Lesk, 1986) and sense-tagged training corpus (Navigli, 2009). Creation of such knowledge structures is a costly and time taking process which requires extensive amount of domain resources and linguistic expertise. Along with this, domain expertise is also needed to create and select hand crafted features and rules from the training data which are required in the automated methods. These requirements make it difficult to design a WSD algorithm for (6500+) (Nakov and Ng, 2009) “resource-poor” languages.

The existing literature on WSD methods report that the naive Most Frequent Sense (MFS) baseline obtained from a sense-tagged corpus is very hard to beat (Navigli, 2009; Bhingardive et al., 2015b). When (Preiss et al., 2009) tried to refine the selection of most frequent sense by using supplementary linguistic resources like POS tagger and Lemmatizer of the concerned language they found that performance of such a system is limited by the performance of used linguistic resources. This observation shows that for resource-poor languages use of other linguistic resources is not much beneficial in WSD task, since their performances are also dependent on the availability of tagged/knowledge corpus. This inspires us to explore methods for WSD which do not rely on other linguistic resources and can take advantage of contextual information about words and
senses present in the sense-tagged and raw untagged training sets. Also, the challenges of requiring domain expertise and non-availability of large sets of sense-tagged data motivated us to develop semi-supervised methods for WSD task. The semi-supervised methods can take advantage of raw untagged data and would require only a moderate or small amount of sense-tagged training data. In semi-supervised scenario, WSD method builds its disambiguation model from a corpus of untagged raw sentences and a set of sense-tagged sentences and is formally defined as:

Using (1) sense IDs set $\Gamma = \{SID_1, SID_2, \ldots, SID_n\}$, (2) sense-tagged sentences set $AD = \{St_1, St_2, \ldots, St_N\}$, where, $St_i = \langle W_1/SID_1, W_2/SID_1, \ldots, W_n/SID_k \rangle$, $W_i$ is a word and $SID_i$ is a sense ID from $\Gamma$ and (3) raw untagged sentences set $RD = \{RS_1, RS_2, \ldots, RS_M\}$, where $RS_i = \langle W_1 W_2 \ldots W_m \rangle$, build a WSD model $\Theta$ which outputs the best sense ID sequence $\langle SID_1, SID_2, \ldots, SID_l \rangle$ for an input sequence of words $\langle W_1 W_2 \ldots W_l \rangle$.

Here, we propose a semi-supervised WSD method which uses the concept of context based list (Rani et al., 2016) to build the WSD model from a set of sense-tagged and raw untagged training corpus. Our proposed method is also influenced by the one sense per collocation hypothesis of Yarowsky (1993) which tells that the sense of a word in a document is effectively determined by its context (Yarowsky, 1995). Our approach takes help of raw untagged data and expands the notions of context and context based list (Rani et al., 2016) to tackle the data sparsity issue. Our method does not require any preprocessing such as, stop/non-content word removal and feature generation and selection from the sense-tagged training corpus. It works without using any additional knowledge structure like dictionary etc., other than the small sense-tagged corpus and moderate sized raw untagged data. This is easily obtainable even for resource-poor languages.

The obtained results show that our method performs well even with very small sized sense-tagged training data for Hindi and Marathi languages and its performance is better than the Random Baseline (Navigli, 2009) which selects a random sense for each polysemous test word, comparable to the Most Frequent Sense (MFS) baseline that selects the most frequent sense available in the sense-tagged training corpus for each polysemous word and at par with the reported results on the used datasets (Bhingardive et al., 2015a; Bhingardive et al., 2013; Khapra et al., 2011a; Khapra et al., 2011b; Khapra et al., 2008).

Rest of the paper is organized as follows: Section 2 presents related work. Section 3 describes our proposed approach. Section 4 presents and discusses the results and Section 5 concludes the paper and mentions future work directions.

## 2 Related Work

Generally, all the existing WSD techniques can be categorized into one of the following approaches (Navigli, 2009; Pal and Saha, 2015): i) Knowledge based approach, which uses knowledge structures like, WordNet (Fellbaum, 1998; Banerjee and Pedersen, 2002) or machine readable dictionaries (Lesk, 1986), ii) Supervised approach, which uses machine learning (Kågebäck and Salomonsson, 2016) and statistical methods (Iacobacci et al., 2016) on manually created sense-tagged training corpus. It also requires domain expertise for creating and selecting features and rules to be used for preprocessing and transforming the training data into the form required for designing the algorithm (Navigli, 2009; Iacobacci et al., 2016), iii) Unsupervised approach, which uses large amount of raw untagged training corpus (Pedersen and Bruce, 1997; Lin, 1998) to find word clusters which discriminates the senses of the words in different clusters, or use multilingual parallel corpora (Ide et al., 2002; Bhingardive et al., 2013), a knowledge resource like WordNet (Patwardhan et al., 2007; Chen et al., 2009; Bhingardive et al., 2015b; Bhingardive et al., 2015a) or multilingual dictionary (Khapra et al., 2011a), and iv) Semi-supervised approach, that uses both sense-tagged and untagged data in different proportions with different methods like, co-training with multilingual parallel corpora (Yu et al., 2011), bootstrapping (Yarowsky, 1995; Khapra et al., 2011b), neural network (Taghipour and Ng, 2015; Yuan et al., 2016) and word sense induction (Baskaya and Jurgens, 2016).

All types of WSD algorithms require knowledge structures and resources like, WordNet (Fellbaum, 1998; Banerjee and Pedersen, 2002), machine readable dictionaries (Lesk, 1986), sense-tagged training corpus (Navigli, 2009), parallel corpora and large untagged raw corpus. Creation
of such knowledge structures and resources is a costly and time taking process which requires extensive amount of domain resources and linguistic expertise. Due to this, for resource-poor languages, special methods are needed which can handle data sparsity issue present in sense-tagged training data and can work with small/moderate set of untagged corpus without requiring knowledge structures and linguistic resources.

To handle the WSD task related challenges of resource-poor languages some specific methods have been proposed. For Chinese language, Yang and Huang (2012) propose handling data sparsity issue by using synonyms for expansion of context, their first method regards synonyms as topic contextual feature to train Bayesian model and second method treats context words made up of synonyms as pseudo training data. Baskaya and Jurgens (2016) propose a Word Sense Induction and Disambiguation (WSID) (Agirre and Soroa, 2007) model in which they combine a small amount of sense-tagged data with information obtained from word sense induction (a fully unsupervised technique that automatically learns the different senses of a word based on how it is used). Yu et al. (2011), Kaphra et al. (2011b), Kaphra et al. (2011a) and Bhingardive et al. (2013) propose methods to use one language to help other language by means of multilingual parallel corpora, multilingual dictionary, translation and bilingual bootstrapping. Mancini et al. (2016) and Bhingardive et al. (2015a) propose to use word and sense embeddings derived from raw untagged data and WordNet. In this method a large raw corpus is needed to obtain word embeddings.

Bhingardive et al. (2015a), Bhingardive et al. (2013), Kaphra et al. (2011a), Kaphra et al. (2011b) and Kaphra et al. (2008) have reported results on the same dataset which we have used in our experiments. The method used in Kaphra et al. (2008) combines sense distributions and sense co-occurrences learned from corpora with semantic relations present in WordNet by specially selecting linguistic features from the sense-tagged data, WordNet, multilingual sense dictionary and a parallel corpus. Kaphra et al. (2011b) uses bilingual bootstrapping in which, a model is first trained using the seed annotated data of one language and then it is used to annotate the untagged data of other language and vice versa using parameter projection. Then from both the languages un-tagged instances annotated with high confidence are added to their seed data and the above process is repeated. Kaphra et al. (2011a) uses an unsupervised bilingual Expectation Maximization (EM) based approach requiring synset-aligned bilingual dictionary and in-domain corpora of the concerned language pairs to estimate sense distributions of words in one language based on the raw counts of the words in the aligned synset in the other language. Bhingardive et al. (2013) add use of context in this EM method (Kaphra et al., 2011a) and approximate the co-occurrence counts using WordNet-based similarity measures. Bhingardive et al. (2015a) further extends this EM method by using distributional similarity obtained from Word Embeddings to approximate the co-occurrence counts.

3 Proposed Semi-supervised Word Sense Disambiguation Method

Since a context can occur in multiple places in the text, we utilize the contextual similarity property based on one sense per collocation hypothesis of Yarowsky (1993) to develop our semi-supervised WSD method. We build upon the concept of context based list (CBL) proposed by Rani et al. (2016) for POS-tagging. They call the list of words occurring in a particular context as CBL and use association rule mining (Agrawal et al., 1993) for obtaining effective context based POS tagging rules from the set of tagged and raw untagged training data. We extend their idea by supplementing CBL with the concepts of extended context list, context based sense list and context based word list (defined below) to handle the peculiar problems of WSD due to data sparsity like:

1. Non availability of matching contexts of a word in sense-tagged training set. Use of raw untagged data with concept of extended context list helps in dealing with this problem.

2. Non availability of words in sense-tagged training set. Use of raw untagged data with concept of context based lists helps in dealing with this problem.

3. Large imbalance in frequencies of senses associated with a word in training set. Defined threshold parameters and context based lists help in handling this problem.

Our notion of context is a word pair, we use the left and right immediate neighboring words of a
Algo_Present($SIDListSet$, $MWordTaggedListSet$, $MWordUntaggedListSet$, $Wi$, $Wtl$, $Wtr$)
1. If test word $W_i$ and its context ($W_{tl}, W_{tr}$) is present as trigram ($W_{tl}, W_i, W_{tr}$) in sense-tagged text collection Then:
   2. Find the corresponding sense IDs of $W_i$ from set $SIDListSet$ and return the sense ID having highest $W_i$ count
3. Else:
   4. Find set $ExpandTestConPList$ of contexts similar to ($W_{tl}, W_{tr}$) by finding its extended Context List using set $MWordTaggedListSet$
   5. Find set $ProbTestSIDList$ of all available sense IDs of $W_i$ with their counts from sense-tagged text collection
   6. From set $ExpandTestConPList$ find the contexts which are present in sense-tagged text collection with $W_i$ as trigram using set $MWordTaggedListSet$ and from these trigrams select those having highest $ExtContextCount$ value in set $ExpandTestConPList$ to make set $maxProbConSet$
   7. For each context ($W_{pl}, W_{ptr}$) of set $maxProbConSet$:
      8. Find the sense IDs associated with ($W_{pl}, W_{ptr}$) using the set $SIDListSet$ and filter out those which exist in $ProbTestSIDList$ to make set $FinalTestSIDList$
   9. If $FinalTestSIDList$ is not empty Then:
      10. Return the sense ID from $FinalTestSIDList$ having highest $W_i$ count
   11. Else:
      12. If Context Based Word List of context ($W_{tl}, W_{tr}$) obtained from set $MWordUntaggedListSet$ contains test word $W_i$ Then:
      13. Find the sense IDs associated with ($W_{tl}, W_{tr}$) using set $SIDListSet$ and filter out those which exist in $ProbTestSIDList$ to make set $ConFinalTestSIDList$
      14. If $ConFinalTestSIDList$ is not empty Then:
      15. Return the sense ID from $ConFinalTestSIDList$ having highest $W_i$ count
      16. Else:
      17. Return the sense ID from $ProbTestSIDList$ having highest $W_i$ count
   18. Else:
      19. Return the sense ID from $ProbTestSIDList$ having highest $W_i$ count

Algo 1: Algorithm to find Sense ID of words present in sense-tagged text collection.

word/sense ID in a sentence/phrase as its context. Formally, in a given trigram ($W_{i-1}, W_i, W_{i+1}$) of words, ($W_{i-1}, W_{i+1}$) word pair is called context of $W_i$. The preceding word $W_{i-1}$ is called left context and succeeding word $W_{i+1}$ is called right context. Note that, in a text collection there can be multiple contexts available for a word. We use these terms in defining following concepts used in our WSD method:

**Single Sense Word List** is a list of word instances (with associated single sense ID) which have only one sense ID associated with them in the sense-tagged text collection.

**Context Based Word List** is a list of word instances from a text collection sharing the same context. For a given context, ($W_i, W_r$), its context based word list is the list of all words $W_m$ having ($W_i, W_r$) as one of their contexts in the text collection. This list allows to store multiple instances of a word.

**Context Based Sense List** is a list of sense ID instances from a sense-tagged text collection sharing the same context. For a given context, ($W_i, W_r$), its context based sense list is the list of sense IDs $SID_m$ having ($W_i, W_r$) as one of their contexts in the sense-tagged text collection. This list can store multiple instances of a sense ID.

**Extended Context List:** For a given context, ($W_i, W_r$) of a word $W_m$, let $PreListSet$ be the set of words obtained from those context based word lists which have left context $W_i$ in their word list and let, $PostListSet$ be the set of words obtained from those context based word lists which have right context $W_r$ in their word list.
**Algo_Absent** *(SIDListSet, MWordTaggedListSet, MWordUntaggedListSet, W_t, W_tl, W_tr)*

1. For test word $W_t$ find Extended Context List set $\text{ExpandTestConTagList}$ of contexts similar to its context $(W_{tl}, W_{tr})$ using set $\text{MWordTaggedListSet}$
2. From set $\text{ExpandTestConTagList}$ select context $(W_{extl}, W_{extr})$ with highest $\text{ExtContextCount}$ value
3. Find Context Based Word List $\text{TrainExConListTest}$ of $(W_{extl}, W_{extr})$ from $\text{MWordTaggedListSet}$
4. If $\text{ListSupport(TrainExConListTest)} \geq \text{Minsizethreshold}$ Then:
   5. Using $\text{SIDListSet}$ find set $\text{ProbTagSenset}$ of sense IDs associated with $\text{TrainExConListTest}$ having $\text{UniqueSenseSupport} \geq (\text{ListSupport(TrainExConListTest)} \times \text{Percentagethreshold})$
   6. From set $\text{ProbTagSenset}$ find and Return $\text{Predsentest}$ having highest value of $\text{TotalSenseSupport}$ and set $\text{Found} = \text{True}$
7. If $\text{Found} \neq \text{True}$ Then:
8. Find Context Based Word List $\text{RawConListTest}$ associated with $(W_{tl}, W_{tr})$ from $\text{MWordUntaggedListSet}$ in which $W_t$ is present
9. Find Context Based Word List $\text{TrainConListTest}$ of $(W_{tl}, W_{tr})$ from $\text{MWordTaggedListSet}$
10. If $\text{ListSupport(RawConListTest)} \geq \text{Minsizethreshold}$ and $\text{ListSupport(TrainConListTest)} \geq \text{Minsizethreshold}$ and Number of matching words between $\text{RawConListTest}$ and $\text{TrainConListTest}$ $\geq$ (size of smaller list among two $- 1$) Then:
   11. Using $\text{SIDListSet}$ find set $\text{ProbTrSenset}$ of sense IDs associated with $\text{TrainConListTest}$ having $\text{UniqueSenseSupport} \geq (\text{ListSupport(TrainConListTest)} \times \text{Percentagethreshold})$
   12. From set $\text{ProbTrSenset}$ find and Return $\text{Predsentest}$ having highest value of $\text{TotalSenseSupport}$ and set $\text{Found} = \text{True}$
13. If $\text{Found} \neq \text{True}$ Then:
14. Find Extended Context List set $\text{ExpandTestConUntagList}$ of contexts similar to context $(W_{tl}, W_{tr})$ using set $\text{MWordUntaggedListSet}$
15. From set $\text{ExpandTestConUntagList}$ select context $(W_{exutl}, W_{exutr})$ with highest $\text{ExtContextCount}$ value
16. Find Context Based Word List $\text{TrainUtExConListTest}$ of $(W_{exutl}, W_{exutr})$ from $\text{MWordTaggedListSet}$
17. If $\text{ListSupport(TrainUtExConListTest)} \geq \text{Minsizethreshold}$ Then:
   18. Using $\text{SIDListSet}$ find set $\text{ProbUtSenset}$ of sense IDs associated with $\text{TrainUtExConListTest}$ having $(\text{UniqueSenseSupport} \geq (\text{ListSupport(TrainUtExConListTest)} \times \text{Percentagethreshold}))$
   19. From set $\text{ProbUtSenset}$ find and Return $\text{Predsentest}$ having highest value of $\text{TotalSenseSupport}$ and set $\text{Found} = \text{True}$
20. If $\text{Found} \neq \text{True}$ Then:
21. Return $\text{NOEXISTSEN}$

**Algo 2:** Algorithm to find Sense ID of words NOT present in sense-tagged text collection.

Let, $\text{FullExtendConListSet}$ be the set of all contexts $(W_{pre}, W_{post})$ prepared by taking word $W_{pre}$ from $\text{PreListSet}$ and word $W_{post}$ from $\text{PostListSet}$. Then, extended context list is the list of all those contexts from $\text{FullExtendConListSet}$ which have $W_m$ in their context based word list. This list contains contexts similar to the given context $(W_t, W_r)$. There is a count value $\text{ExtContextCount}$ associated with each context present in extended context list which shows how many word combinations from $\text{PreListSet}$ and $\text{PostListSet}$ generated that context.
For a list of words \( L \), in which multiple instances of a word can be present, we define following parameters:

- **ListSupport\( (L) \)** is defined as the number of unique words present in \( L \).

- **UniqueSenseSupport** of a particular sense ID, \( SID \), is defined as the number of unique words of \( L \) which have \( SID \) associated with them in the sense-tagged text collection.

- **TotalSenseSupport** of a particular sense ID, \( SID \), is defined as the total number of words of \( L \) (includes repeated occurrences of a word with a sense ID) which have \( SID \) associated with them in the sense-tagged text collection.

- **Minsizethreshold** parameter defines the minimum number of words required to be present in a Context Based Word List to consider it for finding sense of words not present in sense-tagged text collection.

- **Percentagethreshold** parameter is used for calculating percentage of words supporting a particular sense ID in a list of words \( L \).

**Overview of our WSD method**

In the training phase, using a sliding window of size three, we collect all the context based word lists, context based sense lists, single sense word list, word and sense counts from the sense-tagged and raw untagged text collection in a single iteration, taking care of the sentence boundaries. Then in testing phase, Algo 1 and Algo 2 are used to find sense IDs of test words according to their presence/absence in the sense-tagged training set. Algo 1 always provides an output for test words present in sense-tagged training set but Algo 2 returns \( NOEXISTSSEN \) when it is not able to find any valid sense ID for test words not present in sense-tagged training set.

Both the algorithms use directly available immediate context information and indirectly available extended context information from the sense-tagged and raw untagged text collection in a priority order to handle the issues of non availability of matching contexts and imbalance in sense frequencies associated with a word in sense-tagged training set. Information obtained from sense-tagged set is given higher priority. Algo 2 uses raw untagged set to handle issue of non availability of words in sense-tagged training set and takes help of the defined support and threshold parameters to make confident choice of sense ID. Due to these properties it is able to find sense IDs of those test words also which are not present in sense-tagged training set but their associated sense IDs are present. The detailed steps involved in our WSD method are given in Section 3.1.

### 3.1 Word Sense Disambiguation Method

Following steps are used in our WSD method:

1. Find Single Sense Word List from the sense-tagged text collection.
2. Find set \( SIDListSet \) of Context Based Sense Lists of sense IDs from sense-tagged text collection.
3. Find set \( MWordTaggedListSet \) of Context Based Word Lists of words from sense-tagged text collection.
4. Find set \( MWordUntaggedListSet \) of Context Based Word Lists of words from raw untagged text collection.
5. If test word, \( W_t \), present in sense-tagged text collection and is also present in Single Sense Word List then output associated sense ID. Else, find its context \((W_{tl}, W_{tr})\) from test sentence and apply Algo 1.
6. If test word, \( W_t \), is not present in sense-tagged text collection then find its context \((W_{tl}, W_{tr})\) from test sentence and apply Algo 2.

### 4 Results and Discussion

We have used publicly available Health and Tourism domain sense-tagged corpus of Hindi and Marathi languages created by IIT Mumbai\(^1\) (Khapra et al., 2010) and Hindi language raw untagged Health and Tourism domain ILCI data (Jha, 2010). Table 2 gives the dataset details. Table 1 shows average 4-fold cross validation results obtained by our algorithm for polysemous test words which are not present in the sense-tagged training set. Table 3 presents the average 4-fold cross validation results obtained for polysemous test words along with Random Baseline and MFS baseline results.

\(^1\)Available at [http://www.cfilt.iitb.ac.in/wsd/annotated_corpus/](http://www.cfilt.iitb.ac.in/wsd/annotated_corpus/)
The results are presented in terms of Precision, Recall and F-Score accuracy measures as defined below (Navigli, 2009):

\[ \text{Precision} = \frac{\text{No. of correctly predicted test words}}{\text{Total No. of predicted test words}} \] (1)

Here, Total No. of predicted test words = (Total No. of test words - Test words flagged NOEXISTSEN by algorithm).

\[ \text{Recall} = \frac{\text{No. of correctly predicted test words}}{\text{Total No. of test words}} \] (2)

\[ \text{F-Score} = \frac{2 \times \text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \] (3)

Table 1: Average 4-fold cross validation results obtained by our algorithm for polysemous test words NOT present in the sense-tagged training corpus.

| Dataset            | Precision (%) | Recall (%) | FScore (%) |
|--------------------|---------------|------------|------------|
| Hindi Tourism      | 28.93         | 22.90      | 25.56      |
| Marathi Tourism    | 34.50         | 12.00      | 18.00      |
| Hindi Health       | 31.65         | 25.41      | 28.19      |
| Marathi Health     | 32.43         | 8.72       | 13.74      |

The results of Table 1 shows the advantage of our approach in terms of ability to find sense IDs of those test words also which are not present in the sense-tagged training set but their associated sense IDs are present. To the best of our knowledge, currently supervised and semi-supervised WSD methods do not handle words absent in the sense-tagged training corpus. The Random Baseline and MFS baseline methods also can’t find sense IDs for words which are absent in the sense-tagged training set. This ability can be used as a tool to help human annotators by suggesting them probable senses of unknown words while preparing sense-tagged corpus for a language.

To study the effect of parameter values on our approach, we experimented with parameter values Minsize\_threshold = 3, 5, 10 and Percentagethreshold = 0.5, 0.8 and observed that variation in obtained results is very less (±0.5%) which shows that our approach is not very sensitive towards parameter values in this range of values. Following parameter values generated best results for our approach presented in Tables 1, 3 and 5:

1) For Hindi Tourism, Minsize\_threshold = 5 and Percentagethreshold = 0.8. 2) For Hindi Health, Minsize\_threshold = 3 and Percentagethreshold = 0.8. 3) For Marathi Tourism, Minsize\_threshold = 3 and Percentagethreshold = 0.5. 4) For Marathi Health, Minsize\_threshold = 3 and Percentagethreshold = 0.5. Our approach uses both the sense-tagged and raw untagged datasets of each domain mentioned in Table 2. We have divided the original Marathi Health and Tourism datasets into two exclusive parts and used one part as raw untagged set and other as tagged set.

Table 3 shows that results of our approach are better than the Random Baseline results and very close to the MFS baseline results. We can’t directly compare our results with the earlier reported results (see Table 4) on these dataset by Bhingardive et al. (2015a), Bhingardive et al. (2013), Khapra et al. (2011a), Khapra et al. (2011b) and Khapra et al. (2008) due to difference in dataset size and content.

By observing the difference between reported accuracies of approach used by Khapra et al. (2008) and the MFS baseline results reported by them we can conclude that our simple generic approach gives results close to MFS baseline without using any complex feature selection process (domain based and generic) and without requiring too many linguistic and domain resources. For Hindi Tourism, Marathi Tourism and Hindi Health domains our results are better than the results reported by Bhingardive et al. (2015a), Bhingardive et al. (2013), Khapra et al. (2011a), Khapra et al. (2011b) and Khapra et al. (2008) without using huge raw untagged data and without using any linguistic and domain resources like WordNet, a large multilingual parallel corpus or a multilingual dictionary which are required by the other methods.

Table 5 presents results for experiments with sense-tagged set size smaller than $100 \times 10^3$ words and shows that for small training set sizes (less than $50 \times 10^3$ words), Recall of our algorithm is better than MFS and Precision and F-Scores are in close range. Hence, it is a good choice for resource-poor languages, especially for those languages for which resources are in development phase. These results and our other experiments show that as sense-tagged training data size increases performance of our method also improves.
### Table 2: Statistics of sense tagged and raw untagged datasets.

| Dataset                  | Total No. Sentences | Total No. Words | No. of unique Words | No. of unique Polysemous Word Sense IDs | Total No. Polysemous Words | No. of unique Polysemous Words |
|--------------------------|---------------------|-----------------|---------------------|----------------------------------------|----------------------------|-------------------------------|

To study the effect of raw untagged data size, for a particular size sense-tagged training set we varied the raw untagged data size in the range of $2 \times 10^3$ to maximum possible for that dataset and observed that as raw untagged data size increases the number of correctly predicted test words not existing in sense-tagged training set also increases which adds to the overall performance of our approach.

### 5 Conclusions and Future Work

In this paper, we proposed a generic semi-supervised method for Word Sense Disambiguation (WSD) task which uses concept of context-based lists and extended context lists. It makes the WSD model without using domain knowledge from a small set of sense-tagged corpus along with raw untagged text data as training data. It works well with small training data also and handles data sparsity issue. It does not require domain expertise for crafting and selecting features to be used in the algorithm and outputs senses of those test words also which are not present in sense-tagged training set but their associated senses are present. It is generic enough to be used for WSD task of various languages without requiring a large sense-tagged corpus and is especially suitable for resource-poor languages. Our exper-
Table 5: Results obtained for polysemous test words for various sense-tagged training set sizes ($\leq 100 \times 10^3$ words).

iments on Tourism and Health domains of Hindi and Marathi languages show good performance without using any language specific linguistic information.

Future work would be to test it on other languages including English. Further exploration can be done to enhance the property of finding sense IDs of non-existing words. We can also try to include more generic features in the algorithm to enhance performance.
