An orthogonal set of states in multipartite systems is called to be strong quantum nonlocality if it is locally irreducible under every bipartition of the subsystems [Phys. Rev. Lett. 122, 040403 (2019)]. In this work, we study a subclass of locally irreducible sets: the only possible orthogonality preserving measurement on each subsystems are trivial measurements. We call the set with this property is locally stable. We find that in the case of two qubits systems locally stable sets are coincide with locally indistinguishable sets. Then we present a characterization of locally stable sets via the dimensions of some states depended spaces. Although the concept of locally stable set was proposed from the interest in mathematical properties, it also has its physical significance. One finds that locally stable sets of orthogonal product states could not be perfectly distinguishable even with the use of asymptotic local operations and classical communication (LOCC), wherein an error is allowed but must vanish in the limit of an infinite number of rounds. Moreover, we construct two orthogonal sets in general multipartite quantum systems which are locally stable under every bipartition of the subsystems. As a consequence, we obtain a lower bound and an upper bound on the size of the smallest set which is locally stable for each bipartition of the subsystems. Our results provide a complete answer to an open question (that is, can we show strong quantum nonlocality in $\mathbb{C}^{d_i} \otimes \mathbb{C}^{d_i} \otimes \cdots \otimes \mathbb{C}^{d_N}$ for any $d_i \geq 2$ and $1 \leq i \leq N$?) raised in a recent paper [Phys. Rev. A 105, 022209 (2022)]. Compared with all previous relevant proofs, our proof here is quite concise.

solution. One finds that all the proofs of the local indistinguishability are based on the method derived by Walgate and Hardy [8]. They observed that in any locally distinguishable protocol one of the parties must go first, and whoever goes first must be able to perform some nontrivial orthogonality-preserving measurement (here a measurement \( \{ E_x \}_x \in X \) is called nontrivial if not all the positive semidefinite operators are proportional to the identity operator). Therefore, given an orthogonal set of multipartite systems, if one can show that the only possible local orthogonal preserving measurements for each partite are just the trivial measurements, then one can conclude that the set is locally indistinguishable. Although this method has been applied for proving the local indistinguishability of sets of quantum states in many research (see Refs. [31–45]), its strength for proving nonlocality is still worth exploring. For example, we do not even know the minimum number of elements of the nonlocal set that can be derived by this method. From the perspective of mathematical research, it is both necessary and interesting to study the properties of nonlocal sets that can be described by this method. This leads us to propose the concept of locally stable set, an orthogonal set of multipartite quantum states such that the only possible orthogonality preserving measurement on each subsystem are trivial measurements. Under this definition, it is interesting to find how small a locally stable set could be for a given multipartite systems. In this paper, we will provide some bounds on the cardinality of locally stable sets. Although arising from mathematical interest, locally stable sets are also found to have their physical meanings. As a consequence of unavoidable imperfections in the real world, it is more appropriate to ask whether or not a task can be accomplished with the amount of error arbitrary small. If not, the amount of error is impossible to avoid. Recently, Cohen [56] studied whether a set could be perfectly distinguishable under asymptotic LOCC, wherein an error is allowed but must vanish in the limit of an infinite number of rounds. Using a result from their work, we will find that locally stable sets of orthogonal product states are locally indistinguishable even in the sense of asymptotic LOCC.

Recently, Halder et al. [46] introduced a stronger form of local indistinguishability which is based on the concept of local irreducibility. A set of multipartite orthogonal quantum states is said to be locally irreducible if it is not possible to eliminate one or more states from that set using orthogonality preserving local measurement. A set of multipartite orthogonal quantum states is said to be strongly nonlocal if it is locally irreducible for each bipartition of the subsystems. Although lots of study are focus on this topic (see Refs. [47–54]), it remains several open questions one of which is: does the strong quantum nonlocality exist in \( \mathbb{C}^{d_1} \otimes \mathbb{C}^{d_2} \otimes \cdots \otimes \mathbb{C}^{d_N} \) for any \( d_i \geq 2 \) and \( 1 \leq i \leq N \)? Similarly with the concept of strongly nonlocal, we should also study those sets of multipartite orthogonal quantum states that are locally stable for each bipartition of the subsystems. In Theorem 5, we will show that there do exist sets that are locally stable for each bipartition of the subsystems in \( \mathbb{C}^{d_1} \otimes \mathbb{C}^{d_2} \otimes \cdots \otimes \mathbb{C}^{d_N} \) for any \( d_i \geq 2 \) and \( 1 \leq i \leq N \). As locally stable sets are always locally irreducible, sets that are locally stable for each bipartition of the subsystems are always strongly nonlocal. Therefore, our results provide a complete answer to the aforementioned open question affirmatively.

The rest of this article is organized as follows. In Sec. 2, we review the concept of locally indistinguishable set and introduce a special form of quantum nonlocality called locally stable set. In Sec. 3, we first give a complete descriptions of locally stable sets in two qubits systems. Then we give a characterization of locally stable sets by some algebraic quantity known as the rank of some matrix. In Sec. 4, we give two constructions of sets that are locally stable for each bipartition of the subsystems in general multipartite quantum systems. In Sec. 5, we study the strong nonlocality of \( W \) type states in multi-qubit systems. Finally, we draw a conclusion and present some interesting problems in Sec. 6.

## 2 Preliminaries

For any positive integer \( d \geq 2 \), we denote \( \mathbb{Z}_d \) as the set \( \{0,1,\ldots,d-1\} \). Let \( \mathcal{H} \) be an \( d \) dimensional Hilbert space. We always assume that \( \{|0\rangle, |1\rangle,\ldots,|d-1\rangle\} \) is the computational basis of \( \mathcal{H} \). A positive operator-valued measure (POVM) on \( \mathcal{H} \) is a set of positive semidefinite operators \( \{E_x\}_{x \in X} \) such that \( \sum_{x \in X} E_x = \mathbb{I}_\mathcal{H} \) where \( \mathbb{I}_\mathcal{H} \) is the identity operator on \( \mathcal{H} \). A measurement is called trivial if all its POVM elements \( \{E_x\}_{x \in X} \) are proportional to the identity operator, i.e., \( E_x \propto \mathbb{I}_\mathcal{H} \). For a finite set \( \mathcal{S} \), we denote \( |\mathcal{S}| \) the number of elements in that set. Throughout this paper, we do not normalize states for simplicity.

Now we give a brief review of some concept related to local discrimination of quantum states.

**Definition 1 (Locally indistinguishable)** A set of orthogonal pure states in multipartite quantum systems is said locally indistinguishable, if it is not possible to distinguish the states by using LOCC.

**Definition 2 (Locally irreducible)** An orthogonal set of pure states in multipartite quantum systems is locally irreducible if it is not possible to eliminate one or more states from the set by orthogonality-preserving local measurements.

It has been pointed out that locally irreducible sets are always locally indistinguishable but the the opposite case is not true. Note that every LOCC protocol that distinguishes a set of orthogonal states
is a sequence of orthogonality preserving local measurements (OPLM). There is a sufficient condition to prove that an orthogonal set is locally indistinguishable or even locally irreducible: in each subsystem can only perform a trivial orthogonality preserving local measurement. Given an orthogonal set \( S \) of pure states \( \{|\Psi_i\rangle\}_{i=1}^n \) in multipartite systems \( \otimes_{i=1}^N \mathcal{H}_{A_i} \), now we review a general method to show the local indistinguishability or local irreducibility of \( S \): if the set could be locally distinguished or locally reducible, then at least one of the parties could start with a nontrivial orthogonality preserving measurement. For example, if \( A_n \) takes the first nontrivial orthogonality preserving measurement \( \{E_x = M_x^1M_x^2\}_x \) in the protocol, then at least one of \( E_x \) is not proportional to \( I_{A_n} \) and the set of states \( \{M_x \otimes I_{A_n}|\Psi_i\rangle\}_{i=1}^n \) remain orthogonal for all \( x \) where \( A_n := \{A_1, A_2, \ldots, A_N\} \setminus \{A_n\} \), i.e.,

\[
(\Psi_j|E_x \otimes I_{A_n}|\Psi_i\rangle = 0, \text{ for } 1 \le i \neq j \le n. \tag{1}
\]

Therefore, if one can show that \( E_x \propto I_{A_n} \) from Eqs. (1) for all \( n \), then one can conclude that the set is locally indistinguishable and locally irreducible. This motivates us to introduce the following concept.

**Definition 3 (Locally stable)** An orthogonal set of pure states in multipartite quantum systems is said to be locally stable if the only possible orthogonality preserving measurement on the subsystems are trivial measurements.

![Figure 1](image.png)

**Figure 1:** This is a schematic figure on the relations of the three concepts: locally indistinguishable, locally irreducible, locally stable.

By the definition of locally stable set and the above proving strategy for a set to be locally irreducible, one finds that locally stable sets are always locally irreducible. Moreover, there exist locally irreducible sets that are not locally stable. In fact, the four Bell states

\[
S_B := \{|\psi_\pm\rangle := |00\rangle \pm |11\rangle, |\phi_\pm\rangle := |01\rangle \pm |10\rangle\}
\]

are locally irreducible no matter looking them as two qubit states or as two qutrit states. However, they are not locally stable in two qutrit systems \( \mathbb{C}^3 \otimes \mathbb{C}^3 \) as \( \{|0\rangle_A |0\rangle_B + |1\rangle_A |1\rangle_B, |2\rangle_A |2\rangle_B\} \) is a nontrivial orthogonality-preserving measurement for Alice. Therefore, locally stable sets present the strongest form of quantum nonlocality among the three classes: locally indistinguishable sets, locally irreducible sets and locally stable sets (See Figure 1).

There is some other form of stronger nonlocality considering the partition of the subsystems. In fact, a set of orthogonal pure states in multipartite quantum system is said to be genuinely nonlocal \([40, 45]\) if it is locally indistinguishable under each bipartition of the subsystems. For the locally irreducible settings, Halder et al. \([46]\) introduced the strongly nonlocal set as the set of orthogonal pure states in multipartite quantum system such that it is locally irreducible under each bipartition of the subsystems. Therefore, in the setting of locally stable, it is natural to study those sets of orthogonal pure states in multipartite quantum systems such that they are locally stable under each bipartition of the subsystems. In fact, sets with such property are called strongest nonlocal sets in Ref. \([51]\). It is easy to deduce that strongest nonlocal sets are always strongly nonlocal and genuinely nonlocal.

In this paper, we mainly consider whether a given orthogonal set of multipartite states is locally stable or is of strongest nonlocality. Let \( \mathcal{H} = \otimes_{i=1}^N \mathcal{H}_{A_i} \) whose local dimensions are \( \dim_{\mathcal{H}_{A_i}} = d_i \). We denote \( s(d_1, d_2, \ldots, d_N) \) the smallest number of elements of those orthogonal sets in \( \mathcal{H} \) that are locally stable. And we denote \( S(d_1, d_2, \ldots, d_N) \) the smallest number of elements of those orthogonal sets in \( \mathcal{H} \) that are of strongest nonlocality. In this work, we will give some bounds on the two quantities.

### 3 Characterization of locally stable set and lower bounds on \( s(d_1, d_2, \ldots, d_N) \) and \( S(d_1, d_2, \ldots, d_N) \)

First, we give a complete description of the locally stable sets in two qubits systems. The proof is very similar with that in Ref. \([8]\) where they considered locally indistinguishable sets.

**Theorem 1** Let \( S = \{|\Psi_i\rangle\}_{i=1}^l \) be an orthogonal set of pure states in \( \mathbb{C}^2 \otimes \mathbb{C}^2 \). Then \( S \) is locally stable if and only if it is locally indistinguishable. In fact, \( S \) is locally stable if and only if \( |S| \geq 3 \) and contains at least two entangled states.

**Proof.** If \( S \) is locally stable, it is obviously locally indistinguishable. If \( S \) is not locally stable, then one of the parties may perform some nontrivial orthogonality preserving local measurement. Without loss of generality, we assume the first party can perform such a measurement. Hence there exists a semidefinite positive operator \( E_x = M_x^1M_x^2 \) which
is not proportional to $I_2$ such that the elements in $S' := \{M_x \otimes I_2 | \{v_i \}_{i = 1, \cdots , l} \}$ are mutually orthogonal. By the singular value decomposition, there are two orthonormal sets \{\{v_1, \cdots , v_l\} \} and \{\{w_1, \cdots , w_l\} \} such that

$$M_x = \lambda_1 |v_1\rangle\langle w_1| + \lambda_2 |v_2\rangle\langle w_2|$$

where $\lambda_1, \lambda_2 \geq 0$ are real numbers. As $E_x$ is not proportional to $I_2$, we have $\lambda_1 \neq \lambda_2$. Each $|\psi_i \rangle$ ($1 \leq i \leq l$) can be expressed as the following form

$$|\psi_{ij} \rangle = |v_1 \rangle \otimes |\psi_{1i} \rangle + |v_2 \rangle \otimes |\psi_{2i} \rangle$$

where $|\psi_{ij} \rangle$ may be unnormalized and even be a zero vector. As both $S$ and $S'$ are orthogonal sets, we have

$$\langle \psi_{11} | \psi_{12} \rangle \langle \psi_{12} | \psi_{11} \rangle = 0, \quad \lambda_1 |\psi_{11} \rangle \langle \psi_{12} | + \lambda_2 |\psi_{12} \rangle \langle \psi_{11} | = 0$$

for $1 \leq i \neq j \leq l$. Therefore, we have $\langle \psi_{11} | \psi_{11} \rangle = \langle \psi_{12} | \psi_{12} \rangle = 0$ as $\lambda_1 \neq \lambda_2$. With this at hand, Alice and Bob can provide a local protocol to distinguish the set $S$. In fact, Alice can perform the measurement $\pi_A := \{|w_1 \rangle \langle w_1|, |w_2 \rangle \langle w_2|\}$ to the set $S$. For each outcome of this measurement, the possible states of Bob’s party are orthogonal and hence can be distinguished by himself after receiving the outcome of Alice.

The remaining result can be deduced from the known result (see Ref. [8]) that $S \subseteq \mathbb{C}^2 \otimes \mathbb{C}^2$ is locally indistinguishable if and only if $|S| \geq 3$ and $S$ contains at least two entangled states. This completes the proof.

Before studying the locally stable set for general bipartite systems, we introduce some notation that may use throughout this section.

Let $H_A$ and $H_B$ be two Hilbert spaces of dimensional $d_A$ and $d_B$ respectively. Denote $L(H_A, H_B)$ be all the linear operations mapping $H_2$ to $H_1$. There is a linear one-one correspondence between all the linear spaces $L(H_A, H_1)$ and $H_1 \otimes H_2$. Exactly, this correspondence is given by the linear mapping vec : $L(H_A, H_B) \rightarrow H_1 \otimes H_B$ defined by the action on the basis vec$(|i\rangle\langle j|) := |i\rangle\langle j|$. More generally, if $|a\rangle = \sum_{i \in Z_{d_A}} a_i |i\rangle \in H_1$ and $|b\rangle = \sum_{j \in Z_{d_2}} b_j |j\rangle \in H_2$, then one can check that

$$\text{vec}(|a\rangle \langle b|) = |a\rangle \langle b|$$

where $|\bar{b}\rangle := \sum_{j \in Z_{d_2}} \bar{b}_j |j\rangle$ and $\bar{b}_j$ is the complex conjugate of $b_j$. This mapping is also an isometry, in the sense that

$$\langle M, N \rangle = \langle \text{vec}(M), \text{vec}(N) \rangle$$

where $M, N \in L(H_A, H_B)$. Here the inner product $\langle M, N \rangle$ is defined as $\text{Tr}(M^\dagger N)$ for $M, N \in L(H_A, H_1)$ and $\langle |u\rangle, |v\rangle \rangle$ is defined as $\langle u|v\rangle$ for $|u\rangle, |v\rangle \in H_1 \otimes H_2$.

Let $A \otimes B$ be a composed bipartite systems whose local dimensions are $d_A$ and $d_B$ respectively. Suppose that $\{|i\rangle_A | i \in Z_{d_A}\}$ and $\{|j\rangle_B | j \in Z_{d_B}\}$ are the computational bases of systems $A$ and $B$ respectively. Given an orthogonal set $S = \{|v_k\rangle\}_{k = 1}^n$ of pure states in $H_A \otimes H_B$, our goal is to determine whether there is a nontrivial orthogonality preserving local measurement to this set.

For each $|\psi_k\rangle$, we can express it as the form $|\psi_k\rangle = \sum_{i \in Z_{d_A}} |i\rangle \langle i| |v_k\rangle_B$ where $|\psi_k\rangle_B$ may not be normalized and even may be equal to zero. If $E$ is a POVM element on subsystem $B$ that preserves the orthogonality relation, then we have the equalities $\langle \psi_k |\bar{A} \otimes E |\psi_l\rangle = 0$, for $k \neq l$. Substituting the expressions of $|\psi_k\rangle$ and $|\psi_l\rangle$ to these equations, one obtain that

$$\sum_{i \in Z_{d_A}} \text{Tr} \left( |\psi_k\rangle_B \langle \psi_l| \otimes |\bar{v}_i\rangle_B \right) = \sum_{i \in Z_{d_A}} b_{ij}  = 0$$

Applying Eqs. (3) and (4) to the left hand side of the above equation, one obtains that

$$\langle \text{vec}(E), \sum_{i \in Z_{d_A}} |\psi_k\rangle_B \otimes |\bar{v}_i\rangle_B \rangle = 0$$

whenever $k \neq l$. That is, for each pair $(k, l)$ with $1 \leq k \neq l \leq n$, the vector $\sum_{i \in Z_{d_A}} |\psi_k\rangle_B \otimes |\bar{v}_i\rangle_B$ is orthogonal to the vector $\text{vec}(E)$ in the linear space $H_B \otimes H_B$. Let $D_{A|B}(S)$ denote the linear subspace of $H_B \otimes H_B$ spanned by $\sum_{i \in Z_{d_A}} |\psi_k\rangle_B \otimes |\bar{v}_i\rangle_B$ with $1 \leq k \neq l \leq n$. As one notes that vec$(|B\rangle)$ is a nonzero vector that satisfies all the relations in Eq. (5), we always have

$$\dim_{C}[D_{A|B}(S)] \leq d_B^2 - 1.$$  

Moreover, as the map vec is an isometry, if $\dim_{C}[D_{A|B}(S)] = d_B^2 - 1$, one can conclude that the POVM measurement $M$ that satisfies all the relations in Eq. (5) must be proportional to $I_B$. Similarly, we can define a subspace $D_{B|A}(S)$ of $H_A \otimes H_{A'}$ in which case we use the decomposition of $|\psi_k\rangle = \sum_{j \in Z_{d_A}} |j\rangle \langle j| |\psi_{kj}\rangle_A$ where $|\psi_{kj}\rangle_A$ may not be normalized and even may be equal to zero.

**Theorem 2** Let $S$ be an orthogonal set of pure states in $H_A \otimes H_B$ whose local dimensions are $d_A$ and $d_B$ respectively. Let $D_{A|B}(S)$ and $D_{B|A}(S)$ be the linear spaces defined above. Then the set $S$ is locally stable if and only if both of the following equalities are satisfied

$$\dim_{C}[D_{A|B}(S)] = d_B^2 - 1 \text{ and } \dim_{C}[D_{B|A}(S)] = d_A^2 - 1.$$  

**Proof.** Sufficiency. If $\dim_{C}[D_{A|B}(S)] = d_B^2 - 1$, by the previous statement, the Bob’s site can only start with a trivial orthogonality preserving measurement. If $\dim_{C}[D_{B|A}(S)] = d_A^2 - 1$, so does Alice. Therefore, the set $S$ is locally stable by definition.

Necessity. Suppose not, without loss of generality, we could assume that $\dim_{C}[D_{A|B}(S)] \leq d_B^2 - 2$ as by
construction we always have \( \dim_{\mathbb{C}}[\mathcal{D}_{A|B}(S)] \leq d_B^2 - 1 \). We define \( \mathcal{C}_{A|B}(S) \) as the \( \mathbb{C} \)-linear space spanned by

\[
\{ \sum_{i \in \mathcal{Z}_{d_A}} |\psi_{i,i}\rangle_B | \psi_{i,i}\rangle_B | 1 \leq k \neq l \leq n \}. 
\]

Because that the map \( \psi \) is an isometry, the space \( \mathcal{C}_{A|B}(S) \) has the same dimension as \( \mathcal{D}_{A|B}(S) \). Note that for each \( 1 \leq k \neq l \leq n \), the set with two matrices \( \{ \sum_{i \in \mathcal{Z}_{d_A}} |\psi_{i,i}\rangle_B | \psi_{i,i}\rangle_B , \sum_{i \in \mathcal{Z}_{d_A}} |\psi_{i,i}\rangle_B \} \) is linearly equivalent to the set with the following two Hermitian matrices

\[
H_{kl} := \sum_{i \in \mathcal{Z}_{d_A}} |\psi_{i,i}\rangle_B | \psi_{i,i}\rangle_B + |\psi_{i,i}\rangle_B | \psi_{i,i}\rangle_B , \\
H_{ik} := \sum_{i \in \mathcal{Z}_{d_A}} i|\psi_{i,i}\rangle_B | \psi_{i,i}\rangle_B - i|\psi_{i,i}\rangle_B | \psi_{i,i}\rangle_B .
\]

With this note, we have

\[
\mathcal{C}_{A|B}(S) = \text{span}_{\mathbb{C}}[H_{kl} | 1 \leq k \neq l \leq n].
\]

Now we define \( \mathcal{R}_{A|B}(S) = \text{span}_{\mathbb{R}}[H_{kl} | 1 \leq k \neq l \leq n] \). We claim that

\[
\dim_{\mathbb{R}}[\mathcal{R}_{A|B}(S)] \leq \dim_{\mathbb{C}}[\mathcal{C}_{A|B}(S)].
\]

Clearly, \( \mathcal{R}_{A|B}(S) \subseteq \mathcal{C}_{A|B}(S) \) and all the matrices in \( \mathcal{R}_{A|B}(S) \) are Hermitian. To prove the above claim, it is sufficient to prove that if \( H_1, H_2, \ldots, H_L \in \mathcal{R}_{A|B}(S) \) are \( \mathbb{R} \)-linearly independent, then they are also \( \mathbb{C} \)-linearly independent. If not, there exists not all zero \( x_j + iy_j \in \mathbb{C}, 1 \leq j \leq L \) (here \( x_j, y_j, \in \mathbb{R} \) and we can always assume that some \( x_j \neq 0 \), otherwise multiplying both sides by the complex number \( i \) such that

\[
\sum_{j=1}^{L} (x_j + iy_j)H_j = 0. 
\]

Taking the complex conjugate to both sides, we obtain

\[
\sum_{j=1}^{L} (x_j - iy_j)H_j = 0. 
\]

From Eqs. (7) and (8), we obtain that \( \sum_{j=1}^{L} 2x_jH_j = 0 \) which is contradictory with the assumption that \( H_1, H_2, \ldots, H_L \) are \( \mathbb{R} \)-linearly independent. Therefore, we have

\[
\dim_{\mathbb{R}}[\mathcal{R}_{A|B}(S)] \leq \dim_{\mathbb{C}}[\mathcal{C}_{A|B}(S)] \leq d_B^2 - 2.
\]

We know that all the \( d_B \times d_B \) Hermitian matrices form an \( \mathbb{R} \)-linear space of dimensional \( d_B^2 \). As \( \mathbb{I}_{d_B} \) lies in the completion space of \( \mathcal{D}_{A|B}(S) \) and \( \dim_{\mathbb{R}}[\mathcal{D}_{A|B}(S)] \leq d_B^2 - 2 \), there exists at least some other nonzero Hermitian matrix said \( E_B \) which is orthogonal to the space \( \mathcal{R}_{A|B}(S) \) and the identity matrix \( \mathbb{I}_{d_B} \). Multiplying some nonzero real number, we can always assume that each eigenvalue \( \lambda_j \) of \( E_B \) satisfies \( |\lambda_j| \leq 1/4 \). Then we have both \( E_1 := \mathbb{I}_{d_B}/2 + E_B \) and \( E_2 := \mathbb{I}_{d_B}/2 - E_B \) are semidefinite positive and \( E_1 + E_2 = \mathbb{I}_{d_B} \). Therefore, \( \{E_1, E_2\} \) is a POVM. By definition, \( E_1, E_2 \) lie in the completion space of \( \mathcal{R}_{A|B}(S) \), hence it is an orthogonality preserving measurement with respect to the set \( S \). Moreover, it is easy to see that it is a nontrivial measurement. So this is contradicted to the condition that \( S \) is locally stable. Therefore, we should have \( \dim_{\mathbb{C}}[\mathcal{D}_{A|B}(S)] \geq d_B^2 - 1 \). Combining this with Eq. (6), we deduce \( \dim_{\mathbb{C}}[\mathcal{D}_{A|B}(S)] = d_B^2 - 1 \). This completes the proof.

As the subspace \( \mathcal{D}_{B|A}(S) \) (w.r.t. \( \mathcal{D}_{A|B}(S) \)) is completely determined by \( (n-1)n \) generators, therefore, we can use an \((n-1)n \times d_A^2 \) (w.r.t. \( (n-1)n \times d_B^2 \)) matrix to represent it. And we denote the matrix as \( \mathcal{D}_{B|A}(S) \) (w.r.t. \( \mathcal{D}_{A|B}(S) \)).

Example 1 The set \( \mathcal{S}_B \) with three Bell states is locally stable, where

\[
\mathcal{S}_B := \{|\psi_{\pm}\} := \{|00\} \pm |11\} , |\phi_+\} := \{01\} |10\} .
\]

One can easily calculate out the matrix \( \mathcal{D}_{A|B}(SB) \) as follows

\[
\mathcal{D}_{A|B}(SB) = \begin{bmatrix} 1 & 0 & 0 & -1 \\ 0 & 1 & 1 & 0 \\ 1 & 0 & 0 & -1 \\ 0 & 1 & -1 & 0 \\ 0 & 1 & 1 & 0 \\ 0 & -1 & 1 & 0 \end{bmatrix} .
\]

For example, consider the pair \( \{ |\psi_+\}, |\phi_+\} \) of states. We have \( |\psi_+\} := |0\rangle|\psi_0\rangle + |1\rangle|\psi_1\rangle \) and \( |\phi_+\} := |0\rangle|\phi_0\rangle + |1\rangle|\phi_1\rangle \) where \( |\psi_0\rangle = |\phi_1\rangle = \{0\} \) and \( |\psi_1\rangle = |\phi_0\rangle = \{1\} \). It contributes the vector \( |\phi_0\rangle|\psi_0\rangle \) or \( |\phi_1\rangle|\psi_1\rangle \) to \( \mathcal{D}_{A|B}(SB) \). i.e., the vector \( \{0,1,1,0\} \) under the computational basis \( \{|00\}, |01\}, |10\}, |11\} \). And rank(\( \mathcal{D}_{A|B}(SB) \)) = 3. By symmetry, we can conclude that \( \mathcal{S}_B \) is locally stable.

It is not difficult to generalize the results of Theorem 2 to multipartite systems.

Theorem 3 Let \( S \) be an orthogonal set of pure states in \( \otimes_{i=1}^{N} H_A \), whose local dimension is \( \dim_{\mathbb{C}}(H_A) = d_i \). Then we have the following statements:

(a) The set \( S \) is locally stable if and only if all the equalities \( \dim_{\mathbb{C}}[\mathcal{D}_{A|A}(S)] = d_i^2 - 1 \) are satisfied where we use the notation

\[
\hat{A}_i := \{A_1, A_2, \ldots, A_N\} \setminus \{A_i\}
\]

i.e., the union of all subsystems except the \( A_i \).

(b) The set \( S \) is of strongest nonlocality if and only if all the equalities \( \dim_{\mathbb{C}}[\mathcal{D}_{A_i|A_i}(S)] = d_i^2 - 1 \) are satisfied where we denote

\[
\hat{d}_i = (\prod_{j=1}^{N} d_j)/d_i .
\]
Proof. The proof is similar with the proof in Theorem 2. In fact, the essence in the proof of Theorem 2 shows that $\dim_{\mathbb{C}}[\mathcal{D}_{A_i|A_i}(S)] = d^2_i - 1$ if and only if the $A_i$ party can only perform a trivial orthogonality preserving measurement. The same reason that $\dim_{\mathbb{C}}[\mathcal{D}_{A_i|A_i}(S)] = d^2_i - 1$ if and only if the $\hat{A}_i$ party can only perform a trivial orthogonality preserving measurement. With these two equivalent relations, it is easy to recover the above two statements. \qed

For a given orthogonal set of product states $S = \{\otimes_{n=1}^{N}|\psi_i^{(n)}\rangle\}$ in $\otimes_{n=1}^{N}\mathcal{H}_A$. Define $J_n$ to be the set
$$\{(i,j) \mid \langle \psi_i^{(n)}|\psi_j^{(m)}\rangle = 0; \langle \psi_i^{(m)}|\psi_j^{(m)}\rangle \neq 0 \forall m \neq n\}.$$ The Theorem 3 of Ref. [56] shows that if for every party $n$, the set $L_n := \{|\psi_i^{(n)}\rangle\langle \psi_j^{(n)}| \mid (i,j) \in J_n\}$ spans a space of dimension $d^2_n - 1$, then the set $S$ cannot be perfectly discriminated under asymptotic LOCC. Using this result and noting that $\mathcal{D}_{A_i|A_i}(S) = L_n$, one could easily deduce the following corollary by the statement (a) of Theorem 3.

Corollary 4 Let $S$ be an orthogonal set of pure states in $\otimes_{n=1}^{N}\mathcal{H}_A$, whose local dimension is $d_i$. If $S$ is locally stable, then the perfect discrimination is impossible by asymptotic LOCC wherein an error is allowed but must vanish in the limit of an infinite number of rounds.

Using Theorem 3, we could derive a bound on the cardinality of a locally stable set in multipartite systems.

Theorem 4 (Bounds on the sizes of locally stable sets) Let $S$ be an orthogonal set of pure states in $\otimes_{n=1}^{N}\mathcal{H}_A$, whose local dimension is $\dim_{\mathbb{C}}(\mathcal{H}_A) = d_i$. The we have the following statement:

(a) If the set $S$ is locally stable, then $|S| \geq \max_i(d_i + 1)$. Consequently,
$$s(d_1, d_2, \ldots, d_N) \geq \max_i(d_i + 1).$$

(b) If the set $S$ is of strongest nonlocality, then $|S| \geq \max_i(\hat{d}_i + 1)$
(see Eq. (10) for definition of $\hat{d}_i$). Consequently,
$$S(d_1, d_2, \ldots, d_N) \geq \max_i(\hat{d}_i + 1).$$

Proof. (a) By Theorem 4, we have $\mathcal{D}_{A_i|A_i}(S) = d^2_i - 1$. And by the definition of $\mathcal{D}_{A_i|A_i}(S)$, we have
$$d^2_i - 1 = \dim_{\mathbb{C}}[\mathcal{D}_{A_i|A_i}(S)] \leq |S|^2 - |S|.$$ Therefore, $|S| > d_i$ for each $1 \leq i \leq N$.
(b) The proof is similar with the above proof. \qed

4 Two constructions of strongest nonlocal sets and upper bounds on $S(d_1, d_2, \ldots, d_N)$

Generally, it is difficult to show that the possible orthogonality preserving local measurement for each subsystem is trivial. We list two useful lemmas (developed in Ref. [51]) for verifying the trivialization of such measurement.

**Lemma 1 (Block Zeros Lemma)** Let an $n \times n$ matrix $E = (a_{i,j})_{i,j \in \mathbb{Z}_n}$ be the matrix representation of an operator $E$ under the basis $B := \{|0\rangle, |1\rangle, \ldots, |n-1\rangle\}$. Given two nonempty disjoint subsets $S$ and $T$ of $B$, assume that $\{|\psi_i\rangle\}_{i=0}^{d_1-1}$, $\{|\phi_j\rangle\}_{j=0}^{d_2-1}$ are two orthogonal sets spanned by $S$ and $T$ respectively, where $s = |S|$, and $t = |T|$. If $\langle \psi_i|E|\phi_j\rangle = 0$ for any $i \in Z_s, j \in Z_t$, then $(x|E|y) = (y|E|x) = 0$ for $|x| \in S$ and $|y| \in T$.

**Lemma 2 (Block Trivial Lemma)** Let an $n \times n$ matrix $E = (a_{i,j})_{i,j \in \mathbb{Z}_n}$ be the matrix representation of an operator $E$ under the basis $B := \{|0\rangle, |1\rangle, \ldots, |n-1\rangle\}$. Given a nonempty subset $S$ of $B$, let $\{|\psi\rangle\}_{i=1}^{n}$ be an orthogonal set spanned by $S$. Assume that $\langle \psi|E|\phi\rangle = 0$ for any $i \neq j \in Z_n$. If there exists a state $|x| \in S$, such that $\langle x|E|y\rangle = 0$ for all $|y| \in S \setminus \{|x|\}$ and $\langle x|\psi\rangle \neq 0$ for any $j \in Z_n$, then $\langle y|E|z\rangle = 0$ and $\langle y|E|z\rangle = \langle z|E|z\rangle$ for all $|y|, |z|$.

In this section, we provide two constructions of strongest nonlocal sets: $\mathcal{S}$ (all but one state are genuinely entangled) and $\mathcal{S}_G$ (all states are genuinely entangled).

Let $\mathcal{H} := \mathcal{H}_{A_1} \otimes \mathcal{H}_{A_2} \otimes \cdots \otimes \mathcal{H}_{A_N}$ be an $N$ parties quantum systems with dimensional $d_i$ for the $i$th subsystem. A string $i = (i_1, i_2, \ldots, i_N)$ in $C := \mathcal{Z}_{d_{i_1}} \times \mathcal{Z}_{d_{i_2}} \times \cdots \times \mathcal{Z}_{d_{i_N}}$ is called weight $k$ if there are exactly $k$ nonzero $i_j$’s. And we denote the set of all weight $k$ strings of $C$ as $C_k$ where $0 \leq k \leq N$. Set $c_k := |C_k|$, i.e., the number of elements in $C_k$. For each $k \in \{0, 1, \ldots, N-1\}$, we define
$$S_k := \{|\Psi_{k,i}\rangle \in \mathcal{H} \mid i \in \mathcal{Z}_{c_k}, |\Psi_{k,i}\rangle := \sum_{j \in C_k} \omega_{k,c_k}(j)|j\rangle\}.$$ Here $f_k : C_k \rightarrow \mathbb{Z}_{c_k}$ is any fixed bijection and $\omega_n := e^{2\pi i n}$. Theorem 5 Let $\mathcal{H} := \mathcal{H}_{A_1} \otimes \mathcal{H}_{A_2} \otimes \cdots \otimes \mathcal{H}_{A_N}$ be an $N$ parties quantum systems with dimensional $d_i$ for the $i$th subsystem. The set $S := \cup_{k=0}^{N-1} S_k$ is of strongest nonlocality. Then $|S| = \prod_{n=1}^{N} d_n - \prod_{n=1}^{N} (d_n - 1)$. As a consequence,
$$S(d_1, d_2, \ldots, d_N) \leq \prod_{n=1}^{N} d_n - \prod_{n=1}^{N} (d_n - 1).$$
Proof. First, we show that $A_1 = A_2 A_3 \cdots A_N$ can only perform a trivial orthogonality preserving measurement (OPM). Suppose that $\{M_j^1 M_j^2 \}_{j \in \mathbb{N}}$ is an orthogonality preserving measurement with respect to the set $\mathcal{S}$ which is performed by $A_1$, i.e., $\langle \Psi | I_{A_1} \otimes M_j^1 M_j^2 | \Phi \rangle = 0$ for any two different $| \Psi \rangle, | \Phi \rangle \in \mathcal{S}$. Set $E := I_{A_1} \otimes M_j^1 M_j^2$. Let $k, l \in \mathbb{N}$ and suppose $k \neq k$. As $C_k \cap C_l = \emptyset$, applying Block Zeros Lemma to the sets of base vectors corresponding to $C_k$ and $C_l$, we obtain that

$$\langle i_k | E | j_l \rangle = (j_l | E | i_k) = 0$$

for any $i_k \in C_k$ and $j_l \in C_l$. Now we claim that for any $k \in \{0, 1, \ldots, N-1\}$ if $i_k, i'_k$ are two different strings of $C_k$, then we also have

$$\langle i_k | E | i'_k \rangle = (i'_k | E | i_k) = 0.$$ 

Moreover, $\langle i_k | E | i_k \rangle = \langle 0 | E | 0 \rangle = 0$. As $C_{<N} := \cup_{k<N} C_k$ contains $\{0\} \times \mathbb{Z}_2 \times \cdots \times \mathbb{Z}_2$, from the above relations, one could conclude that $M_j^1 M_j^2 \propto I_{A_1}$.

In the following, we will give a proof of the above claim by induction. First, the claim is true for $k = 0$. Now we assume that this claim is true for $0 \leq k < N - 1$. Let $l = k + 1$ and fix any $j_l = (j_1, j_2, \ldots, j_N) \in C_l$ such that $j_1 \neq 0$. For any $i_l = (i_1, i_2, \ldots, i_N) \in C_l$ which is different from $j_l$. If $i_1 \neq j_1$,

$$(j_l | E | i_l) = (j_l | I_{A_1} \otimes M_j^1 M_j^2 | i_l) = 0.$$ 

If $i_1 = j_1$, set $j_k := (0, j_2, \ldots, j_N)$ and $i_k := (0, i_2, \ldots, i_N)$, by definition, they are different strings of $C_k$.

Moreover,

$$(j_1 | E | i_1) = (j_2 \cdots j_N | M_j^1 M_j^2 | i_2 \cdots i_N) = (j_k | E | i_k) = 0$$

by induction. Applying Block Trivial Lemma to the set of base vectors corresponding to $C_l$, the set $\{|{\Psi_{i_1}}_j\}_{i \in \mathbb{Z}_2}$ and the vector $|j_l\rangle$, we obtain that for any different strings $i_1, i'_1 \in C_l$,

$$\langle i_1 | E | i'_1 \rangle = (i'_1 | E | i_1) = 0,$$

and $\langle i_1 | E | i_1 \rangle = (j_1 | E | j_1)$.

Note that $(j_1 | E | j_1)$ equals to

$$(j_2 \cdots j_N | M_j^1 M_j^2 | j_2 \cdots j_N) = (j_k | E | j_k) = \langle 0 | E | 0 \rangle.$$ 

This completes the proof of the claim. Therefore, the last $(N - 1)$-particles could only start with a trivial OPM.

By the symmetric construction, one can also show that any $(N - 1)$ parties could only start with a trivial OPM. This statement also implies that any $k$ (where $1 \leq k \leq N - 1$) parties could only start with a trivial OPM.

Note that the elements in $\mathcal{S}$ are not always with genuine entanglement. In fact, $|\Psi_0\rangle = |0\rangle$ is fully product states. Now we claim that except this state, all others are with genuine entanglement. We only need to show that $|\Psi_{k,i}\rangle$ $(1 \leq k \leq N-1, i \in \mathbb{Z}_{a_k})$ is entangled for any bipartition of the subsystems. We assume that the bipartition is $\{A_j | i \in I\} \{|A_j | j \in J\}$ where $I, J$ are nonempty subsets of $\{1, 2, \ldots, N\}$, disjoint and $I \cup J = \{1, 2, \ldots, N\}$. Let $A$ and $B$ denote the computational bases of the systems $\{A_j | i \in I\}$ and $\{A_j | j \in J\}$ respectively. Suppose that $|\Psi_{k,i}\rangle = \sum_{a \in A} \sum_{b \in B} \psi_{a,b}(i | b \rangle | b \rangle$. It suffices to prove that the rank of the matrix $(\psi_{a,b})$ is greater than one. Clearly, $k$ can be expressed as two different forms $k = s + t$ such that $0 \leq s \leq |I|$ and $0 \leq t \leq |J|$. Suppose $s = s_1 + t_1 = s_2 + t_2$ such that $0 \leq s_1 < s_2 \leq |I|$ and $0 \leq t_2 < t_1 \leq |J|$. Choose any subsets $I_x \subset I$ $(J_y \subset J)$ such that $|I_x| = s_x$ for $x = 1, 2$ $(|J_y| = t_y$ for $y = 1, 2)$. We define

$$|I, I_x \rangle := \left( \left( \otimes_{j \in I_x} | 1 \rangle \right) \otimes \left( \otimes_{j \notin I_x} | 0 \rangle \right) \right) \in A,$$

$$|J, J_y \rangle := \left( \left( \otimes_{j \in J_y} | 1 \rangle \right) \otimes \left( \otimes_{j \notin J_y} | 0 \rangle \right) \right) \in B,$$

where $x, y \in \{1, 2\}$. The matrix $(\psi_{a,b})$ has the $2 \times 2$ minor

$$|I, I_x \rangle \langle J, J_y | \neq 0$$

where $\alpha \beta \neq 0$. Therefore, the Schmidt rank of $|\Psi_{k,i}\rangle$ across this partition $\{A_j | i \in I\} \{|A_j | j \in J\}$ is greater than one. Hence it is entangled.

In Theorem 5, if we replace the set $\mathcal{S}_0$ by two states $|\Psi_{k,i}\rangle := |0\rangle \pm |1\rangle$ where $|0\rangle = \otimes_{i=1}^N |0\rangle_{A_i}$, $|1\rangle = \otimes_{i=1}^N |1\rangle_{A_i}$ and denote the new total set as $\mathcal{S}_G$, then the set $\mathcal{S}_G$ is genuinely entangled set that also has property of strong nonlocality. In fact, for each $1 \leq k \leq N - 1, i \in \mathbb{Z}_{a_k}$, from the orthogonal relations

$$\langle \Psi_{k,i} | |\Psi_{k,i}\rangle = 0,$$

we can deduce the orthogonal relations $|0| E | \Psi_{k,i}\rangle = 0$. Therefore, the orthogonal relations of $\mathcal{S}_G$ contains those from $\mathcal{S}$ in Theorem 5. Using these relations, we could obtain that $\mathcal{S}_G$ is also of strongest nonlocality.

5 More examples with strongest nonlocality

In this part, we try to use the algebraic quantities in section 3 to find more sets which has the property of strongest nonlocality. The first result is out of our expectation. Using entangled states, three qubits is enough to show the strongest nonlocality. We use the following Pauli gate operations $X, Y, Z$

$$X = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}, \quad Y = \begin{bmatrix} 0 & i \\ -i & 0 \end{bmatrix}, \quad Z = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix},$$

and the identity operation $I$. In $C^2 \otimes C^2 \otimes C^2$, the $W$ state is $|100\rangle + |010\rangle + |001\rangle$. Let $U^{(W)}$ denote the matrix

$$X \otimes I \otimes I + Z \otimes X \otimes I + Z \otimes Z \otimes X.$$
Then the set \( S_W := \{ U^{(W)} | ij k \mid i,j,k \in \mathbb{Z}_2 \} \) (the states can be seen in the following table) is an orthogonal basis whose elements are all locally unitary equivalent to the above \( W \) state [55].

| \( |ijk \rangle \) | \( U^{(W)} |ijk \rangle \) | label |
|----------------|-----------------|------|
| 000            | 010 + 010 + 001 | \( |\psi_1 \rangle \) |
| 001            | 101 + 011 + 000 | \( |\psi_2 \rangle \) |
| 010            | 110 + 000 − 011 | \( |\psi_3 \rangle \) |
| 011            | 111 + 001 − 010 | \( |\psi_4 \rangle \) |
| 100            | 000 − 110 − 101 | \( |\psi_5 \rangle \) |
| 101            | 001 − 111 − 100 | \( |\psi_6 \rangle \) |
| 110            | 010 − 111 + 111 | \( |\psi_7 \rangle \) |
| 111            | 011 − 111 + 110 | \( |\psi_8 \rangle \) |

Using Matlab we can show that the ranks of the matrices \( D_{R||R} (S_W) \) \( (R = A, B, C) \) are all 15. Therefore, by Theorem 3, the set \( S_W \) is of strongest nonlocality. Moreover, the statement holds also for any of its subsets with 6 elements.

Generally, we have an orthonormal basis whose elements are all locally unitary equivalent to the generalized \( W \) state in \( N \)-qubit [55]. For any integer \( N \geq 3 \), we denote

\[
U_N^{(W)} := \sum_{i=1}^{N} Z_1 \cdots Z_{i-1} X_{i} I_{i+1} \cdots I_N.
\]

The set defined by \( S_N^{(W)} := \{ U_N^{(W)} | i \mid i \in \mathbb{Z}_N^2 \} \) is such a set.

**Lemma 3** The set \( S_N^{(W)} \) is an orthogonal set of pure states whose elements are all locally unitary equivalent to the multiqubit \( W \) state \( |W_N \rangle := \sum_{i=1}^{N} |0_1 \cdots 0_{i-1} 1_0_{i+1} \cdots 0_N \rangle \) (see Figure 2).

**Proof.** The prove that \( S_N^{(W)} \) is an orthogonal set, it is sufficient to prove that \( U_N^{(W)} \) is a unitary matrix up to a constant. This can be easily deduced when we notice that the anti-commutative relation \( ZX = −ZX \). Therefore,

\[
U_N^{(W)} U_N^{(W)\dagger} = \sum_{k=1}^{N} (Z_1 \cdots Z_{k-1} X_k I_{k+1} \cdots I_N)(Z_1 \cdots Z_{k-1} X_k I_{k+1} \cdots I_N) = \sum_{k<l} I_1 \cdots I_{k-1}(X_k Z_k + Z_k X_k)Z_{k+1} \cdots Z_{l-1} X_l I_{l+1} \cdots I_N + \sum_{k=1}^{N} I_1 \cdots I_{k-1} I_k I_{k+1} \cdots I_N = N I \otimes N.
\]

Clearly, \( U_N^{(W)} |0 \rangle = |W_N \rangle \) which is exactly the \( N \)-qubit \( W \) state. For any \( i = (i_1, i_2, \ldots, i_N) \in \mathbb{Z}_N^2 \), the state \( |\psi_i \rangle := U_N^{(W)} |i \rangle \) can be written as

\[
|\psi_i \rangle = U_N^{(W)} X_1^{i_1} X_2^{i_2} \cdots X_N^{i_N} |0 \rangle.
\]

One can check that

\[
X_1^{i_1} X_2^{i_2} \cdots X_N^{i_N} \psi_i = \sum_{l=1}^{N} (-1)^{i_1 + \cdots + i_{l-1}} |0_1 \cdots 0_{l-1} 1_0_{l+1} \cdots 0_N \rangle.
\]

For each \( l \in \{1, \ldots, N\} \), define \( \theta_l := i_1 + \cdots + i_{l-1} \), and \( Z(\theta) := |0 \rangle |0 \rangle + (-1)^\theta |1 \rangle |1 \rangle \). Then

\[
\otimes_{l=1}^{N} (Z(\theta_l) X_l^{i_l}) |\psi_i \rangle = |W_N \rangle.
\]

That is, \( |\psi_i \rangle \) is locally unitary equivalent to \( |W_N \rangle \). □

Using the Matlab, we can calculate the rank of theirs corresponding quantities to check whether these sets are locally stable or not.

**Example 2** The set \( S_N^{(W)} := \{ U_N^{(W)} | i \mid i \in \mathbb{Z}_N^2 \} \) is of strongest nonlocality for \( 3 \leq N \leq 8 \).

In fact, by randomly choosing a subset of \( S_N^{(W)} \) with \( 2^N - 2^{N-2} \) elements, we find that it is locally stable for each bipartition for \( 3 \leq N \leq 8 \). We conjecture that the above statement should indeed hold for all \( N \)-qubit systems provided \( N \geq 3 \). Moreover, we have obtained some numerical results on the smallest set that can show the local stableness. Based on our numerical results (for systems with small dimension), we conjecture that the bound in Theorem 3 is even compact!

**Conjecture 1** Let \( \mathcal{H} = \otimes_{i=1}^{N} \mathcal{H}_A_i \) be a \( N \)-parties quantum systems whose local dimension \( \text{dim}_c(\mathcal{H}_A_i) = d_i \geq 2 \). Then the following two statements hold
There exists some orthogonal set \( \{ \psi_i \} \) to \( |W_N \rangle \).

(a) There exists some orthogonal set \( S \) of pure states in \( H \) such that it is locally stable and \( |S| = \max_i \{ d_i + 1 \} \). That is,

\[
s(d_1, d_2, \cdots, d_N) = \max_i \{ d_i + 1 \}.
\]

(b) There exists some orthogonal set \( S \) of pure states in \( H \) such that it is of strongest nonlocality and \( |S| = \max_i \{ \hat{d}_i + 1 \} \). That is,

\[
S(d_1, d_2, \cdots, d_N) = \max_i \{ \hat{d}_i + 1 \}
\]

where \( \hat{d}_i = (\prod_{j=1}^{N} d_j)/d_i \).

6 Conclusion and Discussion

In this paper, we studied a special class of sets with quantum nonlocality, i.e., the locally stable sets. That is, an orthogonal set of pure states in multipartite quantum systems whose possible orthogonality preserving local measurements are just trivial measurements. Locally stable sets are always locally indistinguishable sets. And we found that the two concepts are coincide only in two qubits systems. We obtained an algebraic characterization of locally stable sets. As a consequence, we obtained a lower bound of the cardinality on the locally stable set (and strongest non-local set). Moreover, we showed that locally stable sets of product states cannot be perfect discrimination under asymptotic LOCC wherein an error is allowed but must vanish in the limit of an infinite number of rounds.

Moreover, we presented two construction of sets that are of strongest nonlocality. Their proofs can be directly verified via two basic lemmas developed in Ref. [51]. One of the set contains genuinely entangled states except one fully product state. The other set contains only genuinely entangled states. Our result give a complete answer to an open question raised in Ref. [54]. This result gives an upper bound on the smallest cardinality of those orthogonal sets in multipartite systems that are of strongest nonlocality.

There are also some questions left to be considered. We conjectured that there is some set of cardinality \( \max_i \{ d_i + 1 \} \) of orthogonal states in \( \otimes_{i=1}^{N} H_{A_i} \) that is locally stable. We also conjecture that there is some set of cardinality \( \max_i \{ \hat{d}_i + 1 \} \) of orthogonal states in \( \otimes_{i=1}^{N} H_{A_i} \) that is of strongest nonlocality. In addition, it is also to consider the smallest sets of product states that are locally stable. We hope that the study of locally stable sets will enrich our understanding of the quantum nonlocality.

Note added. Very recently, the authors in Ref. [57] provided partial solutions to the part (a) of conjecture 1.
