ABSTRACT

We investigated the Brans-Dicke model with a variable cosmological term (BD) with the coupling constant \( \omega = 10^4 \). We constrained the parameters inherent in this model from a comparison between the Big Bang nucleosynthesis and the observed abundances. Furthermore, we studied the magnitude redshifts \((m-z)\) relations for the BD model with and without another constant cosmological term in a flat universe. Observational data of type Ia supernovae (SNIa) are used in the redshift range of 0.01 < \( z < 2 \). We found that our model with an energy density of the constant cosmological term of 0.7 can explain the SNIa observations, though the model parameters are insensitive to the \( m-z \) relation.

Key words. primordial nucleosynthesis – dark energy – early Universe – cosmology: observations – dark matter – cosmology: theory

1. Introduction

Astronomical observations indicate that the cosmological constant in the very early universe exceeds the present value by some 120 orders of magnitude, which is estimated in modern theories of elementary particles (Weinberg 1989). This is one of the fine-tuning problems in cosmology called the “cosmological constant problem”. To explain the puzzle in cosmology, new modified theories are needed beyond the standard model. The behavior of the cosmological term has motivated various functional forms of the cosmological term. The mechanism of the dynamical reduction of the cosmological term is formulated as a time dependent function (Silviera & Waga 1997) and in terms of a scalar field (Weinberg 1989; Hutner & Turner 1999). On the other hand, generalized scalar tensor theories have been investigated (Wagoner 1970; Endo & Fukui 1977; Fukui et al. 2001).

One of them the Brans-Dicke (BD) theory with a variable cosmological term (Λ) as a function of scalar field (ϕ) (Endo & Fukui 1977). This model has been investigated for the early universe and constrained from the Big Bang nucleosynthesis (BBN) (Arai et al. 1987; Etoh et al. 1997; Nakamura et al. 2006) for the coupling constant \( \omega \leq 500 \). Present observations suggest that the value of \( \omega \) exceeds 40 000 (Berti et al. 2003; Bertotti et al. 2005). Therefore it is worthwhile to reconstrain the parameters in the Brans-Dicke model with a variable cosmological term (BD) for a new value of \( \omega \). The BD model has played a very important role in explaining the characteristics of the early universe (Arai et al. 1987; Etoh et al. 1997; Nakamura et al. 2006). However, we still need an answer to the question “How does this model work at the present epoch?”. Therefore we adopt the magnitude redshift \((m-z)\) relations of type Ia supernovae (SNIa) observations. This is because the cosmological term significantly affects the cosmic expansion rate of the universe at the low redshifts.

The SNIa observations imply that the universe is accelerating at the present epoch (Perlmutter et al. 1999; Riess et al. 1998, 1999).

In Sect. 2 the formulation of the BD model is reviewed. Parameters inherent in this model are constrained in Sect. 3 from the Big Bang nucleosynthesis for \( \omega = 10^4 \). In Sect. 4 the \( m-z \) relation is investigated for the BD model with including another constant cosmological term in a flat universe. Recent SNIa observational data (Astier et al. 2006; Riess et al. 2007; Kessler et al. 2009) are adopted to constrain the models. Concluding remarks are given in Sect. 5.

2. Brans-Dicke model with a variable cosmological term

The field equations for the BD model are written as follows (Arai et al. 1987):

\[
R_{\mu\nu} - \frac{1}{2}g_{\mu\nu}R + g_{\mu\nu}\Lambda = \frac{8\pi}{\phi}T_{\mu\nu} + \omega \phi_{,\mu} \phi_{,\nu} - \frac{1}{2}g_{\mu\nu}\phi_{,\alpha} \phi_{,\alpha}
\]

\[
+ \frac{1}{\phi} \left( \phi_{,\mu} \phi_{,\nu} - g_{\mu\nu} \Box \phi \right) ,
\]

\[
R - 2\Lambda - 2\frac{\partial \Lambda}{\partial \phi} = \frac{\omega}{\phi} \phi_{,\mu} \phi_{,\mu} - \frac{2\omega}{\phi} \Box \phi ,
\]

where \( \phi \) is the scalar field and \( T_{\mu\nu} \) is the energy-momentum tensor of the matter field. The Robertson-Walker metric for homogeneous and isotropic universe writes as (Weinberg 1972):

\[
ds^2 = -dt^2 + a(t)^2 \left( \frac{dr^2}{1-kr^2} + r^2d\theta^2 + r^2\sin^2 \theta d\phi^2 \right) ,
\]
where $a(t)$ is the scale factor and $k$ is the curvature constant. Here we adopt $\epsilon = 1$. The expansion is described by the following equation derived from the $(0, 0)$ component of Eq. (1):

$$\left( \frac{\dot{a}}{a} \right)^2 = \frac{8\pi \rho}{3\phi} - \frac{k}{a^2} + \Lambda + \frac{\omega}{6} \left( \frac{\dot{\phi}}{\phi} \right)^2 - \frac{\ddot{a}}{a^2} - \frac{1}{\phi},$$

(4)

where $\rho$ is the energy density.

We adopt the simplest case of the coupling between the scalar, and the matter field is

$$\Box \phi = \frac{8\pi \mu}{2\omega + 3} T^{\nu}_{\nu},$$

(5)

where $\mu$ is a constant. Assuming a perfect fluid for $T^{\nu}_{\nu}$, Eq. (5) reduces to

$$\frac{d}{dt} (\phi a^3) = \frac{8\pi \mu}{2\omega + 3} (\rho - 3p)a^3,$$

(6)

where $p$ is the pressure.

A particular solution of (2) is obtained from Eqs. (1) and (5):

$$\Lambda = \frac{2\pi (\mu - 1)}{\phi} \rho_{m,0} a^{-3},$$

(7)

where $\rho_{m,0}$ is the energy density of matter at the present epoch.

The gravitational “constant” $G$ is expressed as

$$G = \frac{1}{2} \left( 3 - \frac{2\omega + 1}{2\omega + 3} \mu \right) \frac{1}{\phi}.$$

(8)

The density $\rho$ and the pressure $p$ are replaced by

$$\rho = \rho_m + \rho_Y,$$

(9)

$$p = p_Y = \rho_Y/3,$$

(10)

where the energy density of matter varies as $\rho_m = \rho_{m,0} a^{-3}$. The energy density of radiation is written as $\rho_Y = \rho_{Y,0} a^{-4}$ except $e^8$ epoch: $\rho_Y = \rho_{Y,rad} + \rho_{Y,nu} + \rho_{Y,e}$ at $t \leq 1$ s, where subscripts rad, nu, and e are for photons, neutrinos, and electron-positrons, respectively (Nakamura et al. 2006). The subscript “0” indicates the values at the present epoch.

Then, Eq. (6) is integrated to give

$$\phi = \frac{1}{a^3} \left[ \frac{8\pi \mu}{2\omega + 3} \rho_{m,0} t + B \right],$$

(11)

where $B$ is an integral constant, and here we use the normalized value of $B$: $B^* = B/(10^{-23} \text{ g s cm}^{-3})$.

The original Brans-Dicke theory is deduced for $\epsilon = 1$ and is reduced to the Friedmann model when $\phi = const.$ and $\omega \gg 1$. Physical parameters have been used to solve Eqs. (4), (7), and (11): $G_0 = 6.6726 \times 10^{-8} \text{ cm}^3 \text{ g}^{-1} \text{ s}^{-2}$, $H_0 = 71 \text{ km s}^{-1} \text{ Mpc}^{-1}$ (Spergel et al. 2003), and $\omega = 10^9$ (Berti et al. 2003; Bertotti et al. 2005). Figure 1 shows the evolution of the scale factor in the BDA for the several values of $B^*$. We identify considerable deviations in the BDA from the Friedmann model at $t < 100$ s, which depends on the specific parameters. Therefore the BDA should be constrained from the BBN (Arai et al. 1987; Etoh et al. 1997; Nakamura et al. 2006).

### 3. Parameters constrained from the Big Bang nucleosynthesis

The Big Bang nucleosynthesis provides powerful constraints on possible deviation from the standard cosmology (Malaney & Mathews. 1993). As shown in Fig. 1, the expansion rates of the BDA differ significantly from those of the standard Friedmann model.

The abundance of light elements in the BDA has already been investigated (Arai et al. 1987; Etoh et al. 1997; Nakamura et al. 2006). In the previous studies, the parameters inherent in the BDA have been constrained for $\omega = 500$. But we consider the case $\omega = 10^9$ for convenience, because the Cassini measurements of the Shapiro time delay indicate $\omega \geq 4 \times 10^4$ (Berti et al. 2003; Bertotti et al. 2005). The detailed method of nucleosynthesis is described in Nakamura et al. 2006.

Figure 2 shows the calculated abundances of $^4\text{He}$, $^3\text{He}$, and $^7\text{Li}$ for $B^* = 2$ and $\mu = 0.6$. The $\pm 2\sigma$ uncertainties in nuclear reaction rates are indicated by the dashed lines. The horizontal dotted lines indicate the observational values of $^4\text{He}$, $^3\text{He}$, and $^7\text{Li}$ as follows: $Y_p = 0.2516 \pm 0.0080$ (Fukugita & Kawasaki 2006; Carr et al. 2010), $Y_p = 0.326 \pm 0.075$ (Komatsu et al. 2010), $D/H = (2.82 \pm 0.21) \times 10^{-5}$ (Pettini et al. 2008), $^7\text{Li}/H = (2.34 \pm 0.32) \times 10^{-10}$ (Melendez & Ramirez 2004). Here two observational values of $^4\text{He}$ are used. The solid vertical lines indicate the WMAP constraint of the baryon-to-photon ratio, $\eta = (6.19 \pm 0.15) \times 10^{-10}$ (Komatsu et al. 2010).

The intersection range of the two observational values of $^4\text{He}$ is used to constrain the parameters. We found that the values of $t$ derived from $^4\text{He}$ and $D/H$ are tightly consistent with the value by the WMAP, though the lower limit of $^7\text{Li}/H$ is barely consistent. These agreements lead us to obtain the parameter ranges of $0.0 \leq \mu \leq 0.6$ and $-2 \leq B^* \leq 2$.

### 4. $m - z$ relation in the BDA with and without a constant cosmological term

The distance modulus $\mu_0$ of the source at the redshift $z$ is

$$\mu_0 = m - M = 5 \log_{10} [(1 + z) r] + 25,$$

(12)
where $m$ and $M$ are the apparent and absolute magnitudes respectively, and $\eta$ stands for the radial distance in units of Mpc.

We adopt the SNIa (Astier et al. 2006; Riess et al. 2007; Kessler et al. 2009) for which $\chi^2$ is defined by

$$\chi^2 = \sum_i \frac{(\mu_{\text{obs},i} - \mu_{\text{obs},i}^*)^2}{\sigma_i^2},$$

where $\mu_{\text{obs},i}$ is given by Eq. (12), $\mu_{\text{obs},i}$ and $\sigma_i$ are the observed values of distance modulus and their uncertainties.

For the homogeneous and isotropic universe, the relation between the radial distance and the redshift is derived from the Robertson-Walker metric as (Weinberg 2008)

$$z = \int_0^\infty \frac{dz}{H} = \left\{ \begin{array}{ll} k^{-1/2} \sin^{-1} \left( \sqrt{k} r_i \right) & k = +1, \\
|k|^{-1/2} \sinh^{-1} \left( \sqrt{|k|} r_i \right) & k = -1, 
\end{array} \right.$$

where $H = \dot{a}/a$ is the expansion rate written from Eq. (4) as

$$H = \left[ \frac{1}{4} \left( \frac{\dot{\phi}}{\phi} \right)^2 - (1 + z)^2 k + \frac{\Lambda}{3} + \frac{\omega}{6} \left( \frac{\dot{\phi}}{\phi} \right)^2 + \frac{8\pi \rho}{3} \frac{\dot{\phi}}{\phi} \right]^{1/2} - \frac{1}{2} \frac{\phi}{\dot{\phi}}. \quad (14)$$

We conclude from the WMAP results that we live in a closely geometrically flat universe (Dunckley et al. 2009). The present matter density $\rho_{m0}$ is obtained from Eq. (4) as

$$H_0^2 = \frac{1}{3} \left( \frac{8\pi \rho_{m0}}{\phi_0} + \Lambda_0 \right) + \frac{\omega}{6} \left( \frac{\dot{\phi}}{\phi} \right)^2 - \left( \frac{\phi}{\dot{\phi}} \right)_{0}, \quad (15)$$

$\rho_{m0} = 4\rho_c^{\text{BDA}}/ (\mu + 3)$, $\rho_c^{\text{BDA}} = 3\phi_0 H_0^2/8\pi$, where the $\rho_c^{\text{BDA}}$ is the critical density of BDA.

Using the analogy with the Lemaître model, Eq. (15) is transformed as

$$\Omega_{m0} + \Omega_{\Lambda0} + \Omega_{b0} = 1. \quad (17)$$

Here, the energy density parameters are defined as

$$\Omega_{m0} = \frac{\rho_{m0}}{\rho_c^{\text{BDA}}}, \quad \Omega_{\Lambda0} = \frac{(\mu - 1)\rho_{m0}}{4\rho_c^{\text{BDA}}}, \quad (18)$$

$$\Omega_{b0} = \frac{\omega}{6H_0^2} \left( \frac{\dot{\phi}}{\phi} \right)_{0} - \left( \frac{1}{\phi} \right)_{0}, \quad (19)$$

The value $\Omega_{b0}$ is found to be very low as $7.01 \times 10^{-5}$ for $\mu = 0.6$. If we consider the absolute value of $\Omega_{b0}$ in the parameter range $0.0 \leq \mu \leq 0.6$, its contribution to Eq. (17) is always less than $10^{-5}$. Therefore, as long as we consider the present epoch, contribution from $\Omega_{b0}$ can be neglected.

Figure 3 shows the $m - z$ relation in the BDA for the SNIa observations. Matter is dominant in this model. The energy density of the cosmological term is always less than 20% in the best-fit parameter region predicted in Sect. 3. The energy density of the cosmological term always takes negative values in the obtained parameter region. The parameter $B^+$ is not effective to change the values of $\Omega_{m0}$ and $\Omega_{\Lambda0}$. Because this model is matter dominant, it cannot be constrained by the SNIa observations.

The Friedmann model with the energy density parameters of $(\Omega_{m0}, \Omega_{\Lambda0}) = (1.0, 0.0)$ is merged into the BDA model with the reduced $\chi^2_{\text{red}} \equiv \chi^2/N \approx 4.117$ (where $\chi^2 = 2293$ and $N$ is defined as degrees of freedom). This is inconsistent with the present accelerating universe, which should contain a sufficient amount of dark energy to accelerate the universe. To explain the present accelerating universe, we need some modification of the cosmological term.

As the next approach, the BDA is modified by adding another constant cosmological term $\Lambda_0$. The expansion rate in this model is written by

$$H = \left[ \frac{1}{4} \left( \frac{\dot{\phi}}{\phi} \right)^2 + \frac{\Lambda}{3} + \frac{\rho_{m0}}{3} + \omega \left( \frac{\dot{\phi}}{\phi} \right)^2 + \frac{8\pi \rho}{3} \frac{\dot{\phi}}{\phi} \right]^{1/2} - \frac{1}{2} \frac{\phi}{\dot{\phi}}. \quad (20)$$
The present matter density is

\[ \rho_m = \frac{4 (1 - \Lambda c_0) \rho_{BD}^{c0}}{(\mu + 3)} . \]  

(21)

Here the energy density parameter of the constant cosmological term is fixed to be 0.7. We find that this model is consistent with the SNIa observations as seen in Fig. 3. The total cosmological term becomes large in this model and consistent with the present accelerating universe with reduced \( \chi^2 \sim 0.98 \) (where \( \chi^2 = 546.92 \)). For \( \mu = 0.5 \), the BDA with \( \Lambda c_0 \) predicts \( \Omega_m \sim -4.285 \times 10^{-2} \) and \( \Omega_m = 0.343 \). \( \Omega_m \) always gets negative values in the parameter region of \( \mu \) predicted in Sect. 3. If we consider the total value of energy densities, the contribution from \( \Lambda c_0 \) to the total energy density is always between 60–67%. Therefore, the cosmological term is dominant in the present epoch and can be constrained from the present SNIa observations. We conclude that the BDA with \( \Lambda c_0 \) has nearly the same energy density parameters as the Friedmann model with \( (\Omega_m, \Omega_\Lambda) = (0.3, 0.7) \). Although the cosmological term is not important at the early epoch, it plays a very important role at the present era. All the parameters inherent in the BDA become insufficient as far as the \( m - z \) relation is concerned.

5. Concluding remarks

Previous BBN calculations restricted the parameter range as \(-0.5 \leq \mu \leq 0.8\) and \(-10 \leq B^* \leq 10\) for \( \omega = 500 \) (Nakamura et al. 2006). On the other hand, our high value of \( \omega = 10^3\) leads to the parameter range of \( B^* \sim -2\), which is compatible with the observations, it is worthwhile to examine more generally the functional form of the cosmological term (e.g. Fukui et al. 2001).
