HYPERBOLIC MONODROMY GROUPS FOR THE HYPERGEOMETRIC EQUATION AND CARTAN INVOLUTIONS

ELENA FUCHS, CHEN MEIRI, AND PETER SARNAK

To Nicholas Katz with admiration

Abstract. We give a criterion which ensures that a group generated by Cartan involutions in the automorph group of a rational quadratic form of signature \((n - 1, 1)\) is “thin”, namely it is of infinite index in the latter. It is based on a graph defined on the integral Cartan root vectors, as well as Vinberg’s theory of hyperbolic reflection groups. The criterion is shown to be robust for showing that many hyperbolic hypergeometric groups for \(nF_{n-1}\) are thin.

1. Introduction

Let \(\alpha, \beta \in \mathbb{Q}^n\) and consider the \(nF_{n-1}\) hypergeometric differential equation

\[
Du = 0
\]

where

\[
D = (\theta + \beta_1 - 1)(\theta + \beta_2 - 1) \cdots (\theta + \beta_n - 1) - z(\theta + \alpha_1) \cdots (\theta + \alpha_n)
\]

and \(\theta = z \frac{d}{dz}\).

Assuming, as we do, that \(0 \leq \alpha_j < 1, 0 \leq \beta_j < 1\), then the \(n\)-functions

\[
z^{1-\beta_i} nF_{n-1}(1 + \alpha_1 - \beta_i, \ldots, 1 + \alpha_n - \beta_i, 1 + \beta_1 - \beta_i, \ldots, 1 + \beta_n - \beta_i | z)
\]

where \(\vee\) denotes omit \(1 + \beta_i - \beta_i\), are linearly independent solutions to (1.1). Here \(nF_{n-1}\) is the hypergeometric function

\[
nF_{n-1}(\zeta_1, \ldots, \zeta_n; \eta_1, \ldots, \eta_n-1 | z) = \sum_{k=0}^{\infty} \frac{(\zeta_1)_k \cdots (\zeta_n)_k z^k}{(\eta_1)_k \cdots (\eta_{n-1})_k k!}
\]

and \((\eta)_k = \eta(\eta + 1) \cdots (\eta + k - 1)\).

Equation (1.1) is regular away from \(\{0, 1, \infty\}\) and its monodromy group \(H(\alpha, \beta)\) is generated by the local monodromies \(A, B, C (C = A^{-1}B)\) gotten by analytic continuation of a basis of solutions along loops about \(0, \infty, 1\) respectively, see [B-H] for a detailed description. The local monodromies of equations that come from geometry are quasi-unipotent which is one reason for our restricting \(\alpha\) and \(\beta\) to be rational. We restrict further to such \(H(\alpha, \beta)\)'s which after a suitable conjugation are contained in \(GL_n(\mathbb{Z})\). According to [B-H], this happens if the characteristic polynomials of \(A\) and \(B\), whose roots are \(e^{2\pi i \alpha_j}\) and \(e^{2\pi i \beta_k}\) respectively, are products of cyclotomic

---

1We assume throughout that \(H(\alpha, \beta)\) is primitive – see Section 2.1
polynomials. In particular for each \( n \geq 2 \) there are only finitely many such choices for the pair \( \alpha, \beta \) in \( \mathbb{Q}^n \). [B-H] also determine the Zariski closure \( G = G(\alpha, \beta) \) of \( H(\alpha, \beta) \) explicitly in terms of \( \alpha, \beta \). Furthermore the integrality conditions that we are imposing imply that \( H(\alpha, \beta) \) is self dual so that \( G(\alpha, \beta) \) is either finite, \( \text{Sp}(n) \) (\( n \) even) or \( \text{O}(n) \). The signature of the quadratic form in the orthogonal case is determined by the relative locations of the roots \( \alpha, \beta \) (see Section 2.1).

Our interest is whether \( H(\alpha, \beta) \) is of finite or infinite index in \( G(\mathbb{Z}) = G(\alpha, \beta)[\mathbb{Z}] \). In the first case we say that \( H(\alpha, \beta) \) is arithmetic and in the second case that it is thin. This distinction is important in various associated number theoretic problems (see [SU]) and this paper is concerned with understanding which case happens and which is typical. In a given example, if \( H(\alpha, \beta) \) is arithmetic one can usually verify that it is so by producing generators of a finite index subgroup of \( G(\mathbb{Z}) \), on the other hand if \( H(\alpha, \beta) \) is thin then there is no general procedure to show that it is so.

Our main result is a robust certificate for showing that certain \( H(\alpha, \beta) \)'s are thin.

Until recently, other than the cases where \( H(\alpha, \beta) \) (or equivalently \( G(\alpha, \beta) \)) is finite, there were few cases for which \( H(\alpha, \beta) \) itself was known. For \( n = 2 \) it is well known that all the \( H(\alpha, \beta) \)'s are arithmetic and we show that the same is true for \( n = 3 \). For \( n = 4 \) Brav and Thomas [B-T] showed very recently that the Dwork family [D] \( \alpha = (0, 0, 0, 0), \beta = (\frac{1}{2}, \frac{3}{4}, \frac{1}{2}, \frac{3}{4}) \) as well as six other hypergeometrics with \( G = \text{Sp}(4) \) which correspond to families of Calabi-Yau three-folds, are thin. In fact they show that the generators \( A \) and \( C \) of the above \( H(\alpha, \beta) \)'s play generalized ping-pong on certain subsets of \( \mathbb{P}^3 \), from which they deduce that \( H(\alpha, \beta) \) is a free product and hence by standard cohomological arguments that \( H(\alpha, \beta) \) is thin. On the other hand, Venkataramana shows in [V] that for \( n \) even and

\[
\alpha = \left( \frac{1}{2} + \frac{1}{n+1}, \cdots, \frac{1}{2} + \frac{n}{n+1} \right), \quad \beta = \left( 0, \frac{1}{2} + \frac{1}{n}, \cdots, \frac{1}{2} + \frac{n-1}{n} \right),
\]

\( H(\alpha, \beta) \) is arithmetic (in \( \text{Sp}(n, \mathbb{Z}) \)). In particular, there are infinitely many arithmetic \( H(\alpha, \beta) \)'s. In [S-V] many more examples with \( G = \text{Sp}(n) \) and for which \( H(\alpha, \beta) \) is arithmetic are given. Another example for which \( H \) can be shown to be thin is \( \alpha = (0, 0, 0, \frac{1}{2}), \beta = (\frac{1}{4}, \frac{3}{4}, \frac{1}{4}, \frac{3}{4}) \), see [I]. In this case \( G(\mathbb{R}) \) is orthogonal and has signature \( (2, 2) \) and \( G(\mathbb{Z}) \) splits as a product of \( \text{SL}_2 \)'s.

All of our results are concerned with the case that \( G(\alpha, \beta) \) is orthogonal and is of signature \( (n-1, 1) \) over \( \mathbb{R} \). We call these hyperbolic hypergeometric monodromy groups. There is a unique (up to a scalar multiple) integral quadratic form \( f \) for which \( G(\mathbb{Z}) = \text{O}_f(\mathbb{Z}) \), or what is the same thing an integral quadratic lattice \( L \) with \( \text{O}(L) := G(\mathbb{Z}) \). In Section 2.4 we determine a commensurable quadratic sublattice explicitly which facilitates many further calculations. In this hyperbolic setting \( G(\mathbb{R}) = \text{O}_f(\mathbb{R}) \) acts naturally as isometries of hyperbolic \( n-1 \)-space \( \mathbb{H}^{n-1} \) and we will use this geometry as a critical ingredient to provide a certificate for \( H(\alpha, \beta) \) being thin. Our first result is the determination of the \( \alpha, \beta \)'s for which \( G(\alpha, \beta) \) is hyperbolic, see Theorem 2.6. Firstly, these only occur if \( n \) is odd and for \( n > 9 \) they are completely described by seven infinite parametric families. For \( 3 \leq n \leq 9 \) there are sporadic examples which are listed in Table 2 of Section 3. Our determination of the seven families is based on a reduction to [B-H]'s list of families of \( G(\alpha, \beta) \)'s which are finite (i.e. those \( G(\alpha, \beta) \)'s for which \( G = \text{O}(n) \) and have signature \( (n, 0) \)).

For \( n = 3 \), if \( H(\alpha, \beta) \) is not finite then it is hyperbolic and as we noted all 6 of these hyperbolic groups are arithmetic. This is verified separately for each case, there being no difficulty in
deciding whether a finitely generated subgroup of $SL_2(\mathbb{R})$ is thin or not (the latter is a double cover of $SO(2, 1)$), see Appendix A. For $n \geq 5$ the hyperbolic monodromies behave differently. Our certificate of thinness applies in these cases and it is quite robust as exemplified by

**Theorem 1.** The two families of hyperbolic monodromies $H(\alpha, \beta)$ with $n \geq 5$ and odd

(i) $\alpha = \left(0, \frac{1}{n+1}, \frac{2}{n+1}, \ldots, \frac{n-1}{2n(n+1)}, \frac{n+3}{2n(n+1)}, \ldots, \frac{n}{n+1}\right)$, $\beta = \left(1, \frac{1}{2}, \frac{n}{n+1}, \ldots, \frac{n-1}{n}\right)$

(ii) $\alpha = \left(1, \frac{1}{2n-2}, \frac{3}{2n-2}, \ldots, \frac{2n-3}{2n-2}\right)$, $\beta = \left(0, 0, 1, \frac{1}{2}, \frac{n-3}{n-2}, \ldots, \frac{n}{n-2}\right)$

are thin.

In particular infinitely many of the $H(\alpha, \beta)$'s are thin and as far as we know these give the first examples in the general monodromy group setting of thin monodromy groups for which $G$ is high dimensional and simple.

**Remark.** The normalized $nF_{n-1}$'s corresponding to (i) and (ii) above (see [VIII] for the normalization) are

$$\sum_{k=0}^{\infty} \frac{(2k)!^2(nk)!^2}{((n+1)k)!(k!)^2} z^k$$

and

$$\sum_{k=0}^{\infty} \frac{((2n-2)k)!^2(2k)!}{(k!)^2((n-1)k)!(n-2)!} z^k$$

respectively. The second has integral coefficients while the first does not, hence this arithmetic feature of $F$ is not reflected in the arithmeticity of the corresponding $H$.

Our certificate for thinness applies to a number of the families and many of the sporadic examples. The full lists that we can handle thus far are recorded in Theorems 4.8 and 4.12 of Section 4 as well as Table 2 of Section 5. There remain some families for which the method does not apply (at least not directly). In any case we are led to

**Conjecture 2.** All but finitely many hyperbolic hypergeometric $H(\alpha, \beta)$'s are thin.\(^2\)

---

\(^2\)For $n \geq 5$ there is no general algorithm known to decide this.

\(^3\)It is quite possible that these $H(\alpha, \beta)$'s are all thin for $n \geq 5$.

\(^4\)That useful such $\psi$'s exist in this hyperbolic setting is demonstrated below. If $G(\alpha, \beta)$ is of real rank two or bigger, there are no useful $\psi$'s by Margulis’s normal subgroup theorem [M].
element $C$ in $H(\alpha, \beta)$, which is a linear reflection of $n$-space, induces a Cartan involution of $\mathbb{H}^{n-1}$, that is it is an isometry of $\mathbb{H}^{n-1}$ which is an inversion in a point $p \in \mathbb{H}^{n-1}$. The reflection subgroup $H_r(\alpha, \beta)$ of $H(\alpha, \beta)$ is the group generated by the Cartan involutions $B^kCB^{-k}$, $k \in \mathbb{Z}$ and $H/H_r$ is cyclic. Thus essentially up to commensurability the question of whether $H(\alpha, \beta)$ is thin is a special case of deciding whether a subgroup $\Delta$ of $O_f(\mathbb{Z})$ generated by Cartan involutions is thin or not. We approach this by examining the image of such a $\Delta$ in $K_f$ (when the latter is infinite). At this point the study is about $O_f(\mathbb{Z})$, $K_f$, and a general such $\Delta$ (and $n$ needn’t be odd).

We define a graph $X_f$, the “distance graph,” associated with root vectors of $f$ which is central to the analysis. We assume that $f$ is even (that is $f(x) \in 2\mathbb{Z}$ for $x \in L$) and for $k = 2$ or $-2$ let $V_k(L) = \{v \in L \mid f(v) = k\}$ be the corresponding root vectors (in the case that $f(x,v) \in 2\mathbb{Z}$ for all $x, v \in L$ which comes up in some cases we also allow $k$ to be $\pm 4$). The root vectors define linear reflections lying in $O_f(\mathbb{Z})$ given by $r_v : x \mapsto x - \frac{2f(x,v)}{f(v)}v$. By our choice of the signature of $f$, for $v \in V_{-2}(L)$ the map $r_v$ induces a Cartan involution on $\mathbb{H}^{n-1}$ while for $v \in V_2(L)$ it induces a hyperbolic reflection on $\mathbb{H}^{n-1}$. Assume that the Cartan involutions generating $\Delta$ come from root vectors in $V_{-2}(L)$. $X_f$ has for its vertices the set $V_{-2}(L)$ and we join $v$ to $w$ if $f(v,w) = -3$, this corresponds to $v$ and $w$ having the smallest distance allowed by discreteness, as points in $\mathbb{H}^{n-1}$. The graph $X_f$ is a disjoint union of its connected components $\Sigma_\alpha$ and these satisfy (see Section 4.1 for a detailed statement)

**Proposition 3.**

(i) The components $\Sigma_\alpha$ consist of finitely many isomorphism types.

(ii) Each type is either a singleton or is an infinite regular graph of even degree which is a Cayley graph of a finitely generated Coxeter group.

(iii) If $\Sigma_\alpha$ is a connected component of $X_f$ then the group generated by the corresponding Cartan roots, $R_{-2}(\Sigma_\alpha) = \langle r_v \mid v \in \Sigma_\alpha \rangle$ is commensurable with a subgroup of the reflection group $R_2(L) = \langle r_v \mid v \in V_2(L) \rangle$.

With this Proposition the certificate for showing that $\Delta$ is thin is clear; according to Vinberg and Nikulin $O(L)/R_2(L)$ is infinite except in rare cases (and Nikulin has a classification of these), hence if (iii) is satisfied for the generators of $\Delta$, then $\Delta$ must be thin. The calculations connected with the distance graph are straightforward algorithmically and can even be done explicitly for various parametric families. This leads to the cases discussed in Sections 4 and 5 for which $H(\alpha, \beta)$ is shown to be thin. To end we note that it is possible that a much stronger version of Vinberg’s theorem in the following form is valid: For all but finitely many rational quadratic forms $f$ (at least if $n$ is large enough) the full “Weyl subgroup” $W(f)$ generated by all reflections in $O(L)$ (that is, both those inducing hyperbolic reflections and Cartan involutions on $\mathbb{H}^{n-1}$) is infinite index in $O_f(L)$ (see Nikulin [N2]). If this is true then Conjecture 2 would follow easily from our discussion. In Section 3 we give an example in dimension 4 with $R_2(L)$ being thin and $R_{-2}(L)$ arithmetic, so there is no general commensurability between these groups. Finally, we note that when our analysis of the thinness of $H$ succeeds, it comes with a description of $H$ as a subgroup (up to commensurability) of a geometrically finite subgroup of $R_2(L)$ and this opens the door to determine the group structure of $H$ itself. We leave this for the future.
2. Hyperbolic hypergeometric monodromy groups: preliminaries

2.1. Setup of the problem. We begin by reviewing [B-H] which forms the basis of our analysis. The setup and notation is as in the Introduction. The starting point for studying $H(\alpha, \beta)$ is the following theorem of Levelt.

**Theorem 2.1 ([L]).** For $1 \leq i \leq n$ let $\alpha_i$ and $\beta_i$ be as above. Define the complex numbers $A_1, \ldots, A_n, B_1, \ldots, B_n$ to be the coefficients of the polynomials

$$P(z) := \prod_{j=1}^{k}(z-e^{2\pi i \alpha_j}) = z^n + A_1 z^{n-1} + \cdots + A_n$$

and

$$Q(z) := \prod_{j=1}^{k}(z-e^{2\pi i \beta_j}) = z^n + B_1 z^{n-1} + \cdots + B_n.$$ 

Then $H(\alpha, \beta)$ is the group generated by

$$A = \begin{pmatrix}
0 & 0 & \cdots & 0 & -A_n \\
1 & 0 & \cdots & 0 & -A_{n-1} \\
0 & 1 & \cdots & 0 & : \\
0 & 0 & \cdots & 0 & -A_2 \\
0 & 0 & \cdots & 1 & -A_1
\end{pmatrix}, \\
B = \begin{pmatrix}
0 & 0 & \cdots & 0 & -B_n \\
1 & 0 & \cdots & 0 & -B_{n-1} \\
0 & 1 & \cdots & 0 & : \\
0 & 0 & \cdots & 0 & -B_2 \\
0 & 0 & \cdots & 1 & -B_1
\end{pmatrix}.$$ 

Note that $H(\alpha, \beta)$ can be conjugated into $\text{GL}_n(\mathbb{Z})$ if and only if the polynomials $P(z)$ and $Q(z)$ above factor as cyclotomic polynomials, and so the roots of $P(z)$ and $Q(z)$ are reciprocal, meaning they are left invariant under the map $z \to z^{-1}$. Since we are interested in integral monodromy groups, we will assume this throughout the article. Also, given a group $H(\alpha, \beta)$ as above, one obtains another hypergeometric group $H(\alpha', \beta')$ by taking $0 \leq \alpha', \beta' < 1$ to be $\alpha + d$ and $\beta + d$ modulo 1, respectively. The group $H(\alpha', \beta')$ is called a scalar shift of $H(\alpha, \beta)$, and as pointed out in Remark 5.6 in [B-H], we have that $H(\alpha, \beta) \cong H(\alpha', \beta')$. Thus when classifying all possible pairs $(\alpha, \beta)$ such that $H(\alpha, \beta)$ is integral and fixes a quadratic form of signature $(n-1,1)$ in Section 2.3, we will do so up to scalar shift. Note that for any given $n$ there are only finitely many such groups $H(\alpha, \beta)$.

We also assume that $H$ is irreducible, meaning that it fixes no proper subspace of $\mathbb{C}^n$, and primitive, meaning that there is no direct sum decomposition $\mathbb{C}^n = V_1 \oplus V_2 \oplus \cdots \oplus V_k$ with $k > 1$ and $\dim(V_i) \geq 1$ for all $1 \leq i \leq k$ such that $H$ simply permutes the spaces $V_i$. Finally, we define the reflection subgroup $H_r$ of $H$ to be the group generated by the reflections $\{A^kBA^{-k} | k \in \mathbb{Z}\}$. By Theorem 5.3 of [B-H] we have that the primitivity of $H$ implies the irreducibility of $H_r$. With the notation above, Beukers-Heckman show in [B-H] that $H = H(\alpha, \beta)$ falls into one of three categories. Given a hypergeometric monodromy group $H(\alpha, \beta)$, let

$$c_{\alpha, \beta} := \frac{A_n}{B_n}$$

where $A_n$ and $B_n$ are as in Theorem 2.1. Note that in the cases we consider $c_{\alpha, \beta} = \pm 1$. Then $H(\alpha, \beta)$ belongs to one of the following categories.

(0) A finite group (Beukers-Heckman list such cases completely in [B-H], and we summarize these cases in Theorem 2.2 below)
(1) If \( n \) is even, \( H \) is infinite, and \( c_{\alpha,\beta} = 1 \) then \( H \subset \Sp_n(\Z) \) and \( \Zcl(H) = \Sp_n(\C) \).

(2) If \( n \) is odd and \( H \) is infinite; or if \( n \) is even, \( H \) is infinite, and \( c_{\alpha,\beta} = -1 \), then \( H \subset O_{f_{\alpha,\beta}}(\Z) \) for some rational, unique up to scalar multiple quadratic form \( f = f_{\alpha,\beta} \) in \( n \) variables and \( \Zcl(H) = O_f(\C) \).

As noted in the introduction, in this article we study hypergeometric groups \( H \) which fall into category (2) and such that that \( H \) fixes a quadratic form of signature \((n-1,1)\). We should mention that Beukers-Heckman show that the signature of \( f_{\alpha,\beta} \) in category (2) is given by \((p,q)\) where \( p + q = n \) and

\[
|p - q| = \left| \sum_{j=1}^{n} (-1)^{j+m_j} \right|
\]

where \( m_j = |\{ k \mid \beta_k < \alpha_j \}| \) and the \( \alpha_i \) and \( \beta_i \) are ordered as described at the beginning of this section.

Although we concern ourselves with the case where \( H \) is infinite, irreducible, and primitive, we state below Beukers-Heckman’s classification of all possible finite groups \( H(\alpha, \beta) \). In Section \ref{section:classification} we will need this classification to classify all of the primitive, irreducible hypergeometric groups \( H(\alpha, \beta) \) which we consider – i.e. integral orthogonal of signature \((n-1,1)\). The precise statement of the theorem is taken from [M-S].

**Theorem 2.2 ([B-H], [M-S]).** Let \( \alpha = (\alpha_1, \ldots, \alpha_n) \in \Q^n \) and \( \beta = (\beta_1, \ldots, \beta_n) \in \Q^n \) and let \( H(\alpha, \beta) \) be as before. Define \( a_i := e^{2\pi i \alpha_i} \) and \( b_i := e^{2\pi i \beta_i} \) and let \( a := \{a_1, \ldots, a_n\} \) and \( b := \{b_1, \ldots, b_n\} \). Let \( P(z), Q(z) \) corresponding to \( H(\alpha, \beta) \) be as in Theorem 2.1. If \( H(\alpha, \beta) \) is finite then the corresponding polynomials \( P(z), Q(z) \) are as in one of the cases below.

1. The case where \( H_r \) is primitive: in this case the corresponding polynomials \( P(z) \) and \( Q(z) \) belong to one of two infinite families or to one of 26 sporadic examples. One such infinite family corresponds to
   
   \[ P(z) = \frac{z^{n+1} - 1}{z - 1}, \quad Q(z) = \frac{(z^j - 1)(z^{n+1-j} - 1)}{z - 1} \]

   where \( n \geq 1 \), \( 1 \leq j \leq (n+1)/2 \), \( \gcd(j, n+1) = 1 \). The other infinite family is obtained by replacing \( z \) with \(-z\) above.

2. The case where \( H_r \) acts reducibly on \( \C^n \): in this case Theorem 5.3 of [B-H] implies that \( H_r \) is primitive, and we have that there is some primitive \( \ell \)th root of unity \( \zeta \). Then \( (\alpha, \beta) \) gives the pair \( P(z^\ell), Q(z^\ell) \) where \( P \) and \( Q \) are as in case (1) or correspond to one of the sporadic examples mentioned there.

3. The case where \( H \) is imprimitive and \( H_r \) is irreducible: in this case the corresponding polynomials \( P(z) \) and \( Q(z) \) belong to one of two infinite families. One such family is
   
   \[ P(z) = z^n + 1, \quad Q(z) = (z^j - 1)(z^{n-j} + 1) \]

   where \( n \geq 3 \), \( 1 \leq j \leq n \), and \( \gcd(j, 2n) = 1 \). The other such family is obtained by replacing \( z \) with \(-z\) above.
2.2. Almost interlacing cyclotomic sequences. In this section we classify all almost interlacing cyclotomic sequences (see Definition 2.4). This classification will be used in the next section to classify all hyperbolic hypergeometric monodromies in dimension $n > 9$.

**Definition 2.3.** Two sequences $0 \leq \alpha_1 < \ldots < \alpha_n < 1$ and $0 \leq \beta_1 < \ldots < \beta_n < 1$ are called almost interlacing cyclotomic sequences if the following three conditions hold:

1. $\alpha_i \neq \beta_j$ for every $1 \leq i,j \leq n$.
2. $\prod_{1 \leq i \leq n}(t - e^{2\pi\alpha_i})$ and $\prod_{1 \leq i \leq n}(t - e^{2\pi\beta_i})$ are products of cyclotomic polynomials.
3. $\alpha_1 < \beta_1 < \alpha_2 < \ldots < \alpha_n < \beta_n$ or $\beta_1 < \alpha_1 < \beta_2 < \ldots < \beta_n < \alpha_n$.

Define $r_i := |\{j \mid \beta_j < \alpha_i\}|$ and $s_i := |\{j \mid \alpha_j < \beta_i\}|$. Condition 3 in the above definition is equivalent to the following condition:

$$3^* \quad |\sum_{i=1}^{n}(-1)^{i+r_i}| = |\sum_{i=1}^{n}(-1)^{i+s_i}| = n.$$

**Definition 2.4.** Two sequences $0 \leq \alpha_1 < \ldots < \alpha_n < 1$ and $0 \leq \beta_1 < \ldots < \beta_n < 1$ are called almost interlacing cyclotomic sequences if the following three conditions hold:

1. $\alpha_i \neq \beta_j$ for every $1 \leq i,j \leq n$.
2. $\prod_{1 \leq i \leq n}(t - e^{2\pi\alpha_i})$ and $\prod_{1 \leq i \leq n}(t - e^{2\pi\beta_i})$ are products of cyclotomic polynomials.
3. $|\sum_{i=1}^{n}(-1)^{i+r_i}| = |\sum_{i=1}^{n}(-1)^{i+s_i}| = n - 2$.

Beukers and Hekman classified all interlacing cyclotomic sequences in $[B-H]$. We use their classification in order to classify all almost interlacing cyclotomic sequences. We start with the following lemma:

**Lemma 2.5.** Let $(\alpha_i)_{1 \leq i \leq n}$ and $(\beta_i)_{1 \leq i \leq n}$ be almost interlacing cyclotomic sequences with $n \geq 7$. Then $n$ is odd and $\alpha_{n+1} = \frac{1}{2}$ and $\beta_1 = 0$ or $\beta_{n+1} = \frac{1}{2}$ and $\alpha_0 = 0$. Moreover, if the first possibility happens then one of the following 4 options holds:

1. The sequences $(c_i)_{1 \leq i \leq n}$ and $(d_i)_{1 \leq i \leq n}$ are interlacing cyclotomic sequences where:

$$\begin{cases} 
  c_1 = \beta_1 \\
  c_i = \alpha_{i-1} & 1 < i \leq m \\
  c_i = \alpha_i & m < i \leq n \\
  d_i = \beta_{i+1} & 1 \leq i < m \\
  d_m = \alpha_m \\
  d_i = \beta_i & m < i \leq n 
\end{cases}$$

2. The sequences $(c_i)_{1 \leq i \leq n-1}$ and $(d_i)_{1 \leq i \leq n-1}$ are interlacing cyclotomic sequences where:

$$\begin{cases} 
  c_1 = \beta_1 \\
  c_i = \alpha_{i-1} & 1 < i < m \\
  c_i = \alpha_{i+1} & m \leq i \leq n - 1 \\
  d_i = \beta_{i+1} & 1 \leq i \leq n - 1 
\end{cases}$$
The sequences \((c_i)_{1 \leq i \leq n-1}\) and \((d_i)_{1 \leq i \leq n-1}\) are interlacing cyclotomic sequences where:

\[
\begin{align*}
  c_i &= \alpha_i & 1 \leq i < m \\
  c_i &= \alpha_{i+1} & m \leq i \leq n - 1 \\
  d_i &= \beta_{i+2} & 1 \leq i < m \\
  d_i &= \beta_{i+1} & m < i \leq n - 1 \\
  d_m &= \alpha_m
\end{align*}
\]

The sequences \((c_i)_{1 \leq i \leq n-2}\) and \((d_i)_{1 \leq i \leq n-2}\) are interlacing cyclotomic sequences where:

\[
\begin{align*}
  c_i &= \alpha_i & 1 \leq i < m \\
  c_i &= \alpha_{i+2} & m \leq i \leq n - 2 \\
  d_i &= \beta_{i+2} & 1 \leq i \leq n - 2
\end{align*}
\]

**Proof.** The proof is divided into easy steps:

(a) The sequences \((\alpha_i)_{1 \leq i \leq n}\) and \((\beta_i)_{1 \leq i \leq n}\) are cyclotomic so for every \(t \in (0, 1)\),

\[|\{j \mid \alpha_j = t\}| = |\{j \mid \alpha_j = 1 - t\}|\]

and

\[|\{j \mid \beta_j = t\}| = |\{j \mid \beta_j = 1 - t\}|\]

(b) For every \(1 \leq i \leq n - 1\) denote \(\epsilon_i := (-1)^{[\{j \mid \beta_j \in (\alpha_i, \alpha_{i+1})\}|}\) and \(\delta_i := (-1)^{[\{j \mid \beta_j \in (\beta_i, \beta_{i+1})\}|}.\) The equality \(|\sum_{i=1}^{n}(-1)^{i+r_i}| = n - 2\) implies that exactly one of the following possibilities holds:

(i) \(\{i \mid \epsilon_i = 1\} = \{1\}\)

(ii) \(\{i \mid \epsilon_i = 1\} = \{n - 1\}\)

(iii) \(\{i \mid \epsilon_i = 1\} = \{m - 1, m\}\) for some \(2 \leq m \leq n\).

(c) The symmetry of step (1) shows that option (ii) above is not possible. Furthermore, if option (i) happens then \(\alpha_1 = 0\) while if option (iii) happens then \(n\) is odd, \(m = \frac{n+1}{2}\) and \(\alpha_m = \frac{1}{2}\).

(d) Changing the rolls of the \(\alpha_i's\) and the \(\beta_i's\) we see that \(n\) is odd and either \(\{i \mid \epsilon_i = 1\} = \{1\}\) and \(\{i \mid \delta_i = 1\} = \{\frac{n-1}{2}, \frac{n+1}{2}\}\) or \(\{i \mid \epsilon_i = 1\} = \{\frac{n-1}{2}, \frac{n+1}{2}\}\) and \(\{i \mid \delta_i = 1\} = \{1\}\).

(e) From now on we will assume that \(\{i \mid \epsilon_i = 1\} = \{\frac{n-1}{2}, \frac{n+1}{2}\}\) and \(\{i \mid \delta_i = 1\} = \{1\}\) so \(m = \frac{n+1}{2}\) and \(\alpha_m = \frac{1}{2}\).

(f) Since there are exactly \(n\) \(\alpha_i's\) and \(n\) \(\beta_i's\) we get that:

- If \(\epsilon_i = 1\) then \(|\{j \mid \beta_j \in (\alpha_i, \alpha_{i+1})\}| = 0\).
- If \(\epsilon_i = -1\) then \(|\{j \mid \beta_j \in (\alpha_i, \alpha_{i+1})\}| = 1\).
- If \(\delta_i = 1\) then \(|\{j \mid \alpha_j \in (\beta_i, \beta_{i+1})\}| = 0\).
- If \(\delta_i = -1\) then \(|\{j \mid \alpha_j \in (\beta_i, \beta_{i+1})\}| = 1\) or 3 and equality to 3 happens exactly at one \(i\) for which \(\{m - 1, m, m + 1\} = \{j \mid \alpha_j \in (\beta_i, \beta_{i+1})\}\).

(g) Thus, there are only 4 options:

(1)

\[0 = \beta_1 < \beta_2 < \alpha_1 < \beta_3 < \alpha_2 < \cdots < \beta_m < \alpha_{m-1} < \alpha_m = \frac{1}{2} < \beta_{m+1} < \alpha_{m+2} < \cdots < \beta_{n-1} < \alpha_n < \beta_n.\]
Let \( H \) to scalar shift) the groups in these families, there are several sporadic groups in dimensions \( n > 9 \) up to scalar shift. In addition to groups in these families, there are several sporadic groups in dimensions \( n \leq 9 \) which are listed in Table 2 of Section 5.1 along with all primitive hyperbolic \( H(\alpha, \beta) \) in dimension \( n \leq 9 \).

**Theorem 2.6.** Let \( n \geq 1 \) be odd and let \( P_m, Q_m, P_{m,k}, Q_{m,k} \) be as defined in (2.3) and (2.4). Let \( \alpha = \{\alpha_1, \ldots, \alpha_n\} \) and \( \beta = \{\beta_1, \ldots, \beta_n\} \) where \( \alpha_i, \beta_i \in \mathbb{Q} \) for \( 1 \leq i \leq n \) and let \( H(\alpha, \beta) \) be as in Theorem 2.1. If \( (\alpha, \beta) \) belongs to one of the following families or is a scalar shift of a pair in one of these families, then \( H(\alpha, \beta) \subset O(n-1,1) \). If \( n > 9 \), this list of families completely describes (up to scalar shift) the groups \( H(\alpha, \beta) \subset O_f(\mathbb{Z}) \) where \( f \) is a quadratic form in \( n \) variables of signature \((n-1,1)\).

1) \( \mathcal{M}_1(j,n) \):

\[
\alpha = \left( 0, \frac{1}{2n}, \frac{3}{2n}, \ldots, \frac{n-1}{2n}, \frac{n+1}{2n}, \ldots, \frac{2n-3}{2n}, \frac{2n-1}{2n} \right),
\beta = \left( \frac{1}{j}, \frac{1}{j}, \frac{1}{j}, \frac{1}{2n-j}, \frac{1}{2n-j}, \ldots, \frac{2n-2j-3}{2n-2j}, \frac{2n-2j-1}{2n-2j} \right)
\]

where \( 0 < j < n \) is an odd integer.
2) $\mathcal{M}_2(j, n)$:

\[
\begin{align*}
\alpha &= \left(\frac{1}{2n-2}, \frac{3}{2n-1}, \ldots, \frac{1}{2}, \frac{1}{2}, \ldots, \frac{2n-5}{2n-4}, \frac{2n-3}{2n-4} \right), \\
\beta &= \left(0, 0, 0, \frac{1}{j}, \frac{1}{j}, \ldots, \frac{1}{2}, \frac{1}{2}, \ldots, \frac{2n-7}{2n-6}, \frac{2n-5}{2n-6} \right)
\end{align*}
\]

where $0 < j < n$ is an integer and $j/(n, j)$ is odd.

3) $\mathcal{M}_3(j, n)$:

\[
\begin{align*}
\alpha &= \left(\frac{1}{2n-4}, \frac{3}{2n-3}, \ldots, \frac{1}{2}, \frac{1}{2}, \ldots, \frac{2n-7}{2n-5}, \frac{2n-3}{2n-5} \right), \\
\beta &= \left(0, 0, 0, \frac{1}{j}, \frac{1}{j}, \ldots, \frac{1}{2}, \frac{1}{2}, \ldots, \frac{2n-7}{2n-5}, \frac{2n-3}{2n-5} \right)
\end{align*}
\]

where $0 < j < n - 2$ is an odd integer.

4) $\mathcal{N}_1(j, k, n)$:

\[
\begin{align*}
\alpha &= (b_0, a_1, \ldots, a_{n-1}) \\
\beta &= (a_0, b_1, \ldots, b_{n-1})
\end{align*}
\]

where $(j, k + 1) = 1$, $a_0 = 1/2$, $b_0 = 0$, $e^{2\pi i a_0}, \ldots, e^{2\pi i a_{n-1}}$ are the roots of $P_{n,k}(z)$, and $e^{2\pi i b_0}, \ldots, e^{2\pi i b_{n-1}}$ are the roots of $Q_{n,k}(z)$.

5) $\mathcal{N}_2(j, k, n)$:

\[
\begin{align*}
\alpha &= (0, a_0, \ldots, a_{n-2}) \\
\beta &= (\frac{1}{2}, \frac{1}{2}, b_2, \ldots, b_{n-2})
\end{align*}
\]

where $(j, k + 1) = 1$, $b_0 = 0$, $b_1 = 1/2$, $e^{2\pi i a_0}, \ldots, e^{2\pi i a_{n-2}}$ are the roots of $P_{n-1,k}(z)$, and $e^{2\pi i b_0}, \ldots, e^{2\pi i b_{n-2}}$ are the roots of $Q_{n-1,k}(z)$.

6) $\mathcal{N}_3(j, k, n)$:

\[
\begin{align*}
\alpha &= (\frac{1}{2}, a_0, \ldots, a_{n-2}) \\
\beta &= (0, 0, 0, b_2, \ldots, b_{n-2})
\end{align*}
\]

where $(j, k + 1) = 1$, $b_0 = 0$, $b_1 = 1/2$, $e^{2\pi i a_0}, \ldots, e^{2\pi i a_{n-2}}$ are the roots of $P_{n-1,k}(z)$, and $e^{2\pi i b_0}, \ldots, e^{2\pi i b_{n-2}}$ are the roots of $Q_{n-1,k}(z)$.

7) $\mathcal{N}_4(j, k, n)$:

\[
\begin{align*}
\alpha &= (\frac{1}{2}, a_0, \ldots, a_{n-3}) \\
\beta &= (0, 0, 0, b_1, \ldots, b_{n-3})
\end{align*}
\]

where $(j, k + 1) = 1$, $0 < j < \frac{n-3}{2}$, $e^{2\pi i a_0}, \ldots, e^{2\pi i a_{n-3}}$ are the roots of $P_{n-2,k}(z)$ and $e^{2\pi i b_0}, \ldots, e^{2\pi i b_{n-3}}$ are the roots of $Q_{n-2,k}(z)$.

**Proof.** From the previous section, we have that every family of pairs $(\alpha, \beta)$ for which $H(\alpha, \beta) \subset O(n - 1, 1)$ can be derived from a family of pairs $(\alpha', \beta')$ for which $H(\alpha', \beta')$ is finite, but not necessarily primitive or irreducible. There are several cases to consider.

**Case 1:** $|\alpha'| = |\beta'| = n$.

Without loss of generality, assume $\alpha'_k = 1/2$ for some $k$ and $\beta'_1 = 0$. By Lemma 2.5, letting $\alpha_j = \alpha'_j$ for $j \neq k$, we proceed as follows...
\[ \alpha_k = 0, \]
\[ \beta_j = \beta'_j \text{ for } j \neq 1, \]
\[ \beta_1 = 1/2 \]

we have that \( H(\alpha, \beta) \subset O(n-1,1) \).

Suppose \( H(\alpha', \beta') \) is finite, imprimitive, and irreducible. From Theorem 2.2 there are two infinite families of \((\alpha', \beta')\), the second of which gives pairs that are scalar shifts by 1/2 of the pairs coming from the first family. Since we are only interested in determining pairs up to scalar shift, we consider just one of these families, which has corresponding cyclotomic polynomials \( P_n(z) \) and \( Q_n(z) \) from (2.3) where \( j \) is odd. Up to scalar shift, this yields the family \( \mathcal{M}_1' \):
\[ \alpha = (0, \frac{j}{2n}, \frac{j+1}{2n}, \ldots, \frac{\pi i b_1}{2n}, \frac{\pi i b_2}{2n}, \ldots), \]
\[ \beta = (\frac{j-1}{2n}, \frac{j+1}{2n}, \frac{1}{2n-2j}, \frac{3}{2n-2j}, \ldots, \frac{2n-j-3}{2n-2j}, \frac{2n-j-1}{2n-2j}) \]

where \( j \) is odd. Note that, unlike \((\alpha', \beta')\), the pair \((\alpha, \beta)\) is no longer imprimitive, and still irreducible.

Suppose \( H(\alpha', \beta') \) is finite and reducible or primitive and irreducible. Then for every \( \ell|n \), Theorem 2.2 gives two infinite families of \((\alpha', \beta')\), of which we consider just the first, as the other can be obtained via scalar shift of the first. The corresponding cyclotomic polynomials in this case are \( P_{n,k}(z) \) and \( Q_{n,k}(z) \) from (2.4), where \( j, k, \ell \in \mathbb{N} \), with \((j, k+1) = 1 \) and \( \ell k = n \). Let \( a_0 = 1/2 \) and denote the roots of \( P_{n,k}(z) \) by \( e^{2\pi i a_0}, \ldots, e^{2\pi i a_{n-1}} \). Let \( b_0 = 0 \) and denote the roots of \( Q_{n,k}(z) \) by \( e^{2\pi i b_0}, \ldots, e^{2\pi i b_{n-1}} \). Up to scalar shift, this yields the family \( \mathcal{N}_1' \):
\[ \alpha = (b_0, a_1, \ldots, a_{n-1}), \]
\[ \beta = (a_0, b_1, \ldots, b_{n-1}) \]

Note that the pair \((\alpha, \beta)\) is primitive and irreducible.

**Case 2:** \(|\alpha'| = |\beta'| = n - 1\).

As before, we consider the imprimitive irreducible, and the primitive irreducible or reducible cases.

Suppose \( H(\alpha', \beta') \) is finite, imprimitive, and irreducible. From Theorem 2.2 we have that up to scalar shift the only family of \((\alpha', \beta')\) in this case corresponds to the roots of \( P_{n-1}(z) \) and \( Q_{n-1}(z) \) in (2.3):
\[ \alpha' = (\frac{1}{2n-2}, \frac{3}{2n-2}, \ldots, \frac{2n-j-3}{2n-2}, \frac{2n-j-1}{2n-2}), \]
\[ \beta' = (0, \frac{j}{2n-2}, \frac{j+1}{2n-2}, \frac{3}{2n-2}, \ldots, \frac{2n-j-3}{2n-2}, \frac{2n-j-1}{2n-2}) \]

where \( j/(n,j) \) is odd. According to Lemma 2.5 there are two ways to obtain from \((\alpha', \beta')\) a pair \((\alpha, \beta)\) for which \( H(\alpha, \beta) \) is signature \((n-1,1)\) is obtained as above, giving the two families
\[ \alpha = (\frac{1}{2n-2}, \frac{3}{2n-2}, \ldots, \frac{2n-j-3}{2n-2}, \frac{2n-j-1}{2n-2}), \]
\[ \beta = (0, 0, 0, \frac{1}{2n-2}, \frac{j+1}{2n-2}, \frac{3}{2n-2}, \ldots, \frac{2n-j-3}{2n-2}, \frac{2n-j-1}{2n-2}) \]
where \((j, 2n) = 1\) and

\[
\alpha = \left(0, \frac{1}{2n-2}, \frac{3}{2n-4}, \ldots, \frac{2n-5}{2n-2}, \frac{2n-4}{2n-2}\right),
\]

\[
\beta = \left(\frac{1}{2}, \frac{1}{3}, \frac{1}{5}, \ldots, \frac{1}{2n-3}, \frac{1}{2n-4}, \ldots, \frac{2n-j-3}{2n-2j-2}, \frac{n-j}{2n-2j-2}, \ldots, \frac{n-1}{2n-2j-2}, \frac{n-2}{2n-2j-2}, \frac{n-3}{2n-2j-2}, \ldots, \frac{2n-2j-5}{2n-2j-2}, \frac{2n-3j-5}{2n-2j-2}\right)
\]

where \(j/(n, j)\) is odd. However, since these two families are shifts of each other by \(1/2\), we record them under one family \(\mathcal{M}_2\).

Suppose \(H(\alpha', \beta')\) is finite and reducible or primitive irreducible. From Theorem 2.2, we have that for every \(\ell|n-1\) that there is only one family up to scalar shift of \((\alpha', \beta')\) for which \(H(\alpha', \beta')\) is reducible. Namely, let \(j, k, \ell \in \mathbb{N}\), with \((j, k + 1) = 1\) and \(\ell k = n - 1\). Denote the roots of \(P_{n-1,k}(z)\) in \((2.4)\) by \(e^{2\pi i a_0}, \ldots, e^{2\pi i a_{n-2}}\). Let \(b_0 = 0\), \(b_1 = 1/2\), and denote the roots of \(Q_{n-1,k}(z)\) in \((2.4)\) by \(e^{2\pi i b_0}, \ldots, e^{2\pi i b_{n-2}}\). Then the family

\[
\alpha' = (a_0, \ldots, a_{n-2}),
\]

\[
\beta' = (b_0, \ldots, b_{n-2})
\]

is the only family up to scalar shift in this case such that \(H(\alpha', \beta')\) is reducible. According to Lemma 2.5, there are two ways to obtain a pair \((\alpha, \beta)\) for which \(H(\alpha, \beta)\) is signature \((n-1, 1)\). One way is to remove the term \(b_0 = 0\) and add two \(1/2\)'s to \(\beta'\), and add the term \(0\) to \(\alpha'\), yielding the family \(\mathcal{N}_2\):

\[
\alpha = (0, a_0, \ldots, a_{n-2}),
\]

\[
\beta = \left(\frac{1}{2}, a_1, \ldots, b_{n-2}\right).
\]

Another way is to add the term \(1/2\) to \(\alpha'\), take away the term \(b_1 = 1/2\) from \(\beta'\), and insert two \(0\)'s into \(\beta'\), yielding the family \(\mathcal{N}_3\):

\[
\alpha = \left(\frac{1}{2}, a_0, \ldots, a_{n-2}\right),
\]

\[
\beta = (0, 0, 0, b_2, \ldots, b_{n-2}).
\]

Case 3: \(|\alpha'| = |\beta'| = n - 2\).

Suppose \(H(\alpha', \beta')\) is finite, imprimitive, and irreducible. From Theorem 2.2, we have that up to scalar shift the only family of \((\alpha', \beta')\) in this case is obtained from the roots of the cyclotomic polynomials \(P_{n-2}(z)\) and \(Q_{n-2}(z)\) in \((2.3)\):

\[
\alpha' = \left(\frac{1}{2n-4}, \frac{3}{2n-4}, \ldots, \frac{2n-7}{2n-4}, \frac{2n-5}{2n-4}\right),
\]

\[
\beta' = \left(0, \frac{1}{2}, a_{j-1}, \frac{1}{3}, \frac{1}{5}, \ldots, \frac{1}{2n-3}, \frac{1}{2n-4}, \ldots, \frac{2n-2j-7}{2n-2j-4}, \frac{2n-2j-5}{2n-2j-4}\right)
\]

where \(j\) is odd. The corresponding \((\alpha, \beta)\) for which \(H(\alpha, \beta)\) is signature \((n-1, 1)\) is obtained by adding two \(1/2\)'s to \(\alpha'\), and adding two \(0\)'s to \(\beta'\), yielding the family \(\mathcal{M}_3\):

\[
\alpha = \left(\frac{1}{2n-4}, \frac{3}{2n-4}, \ldots, \frac{1}{2}, \frac{1}{2}, \ldots, \frac{2n-5}{2n-2}, \frac{2n-3}{2n-2}\right),
\]

\[
\beta = \left(0, 0, 0, \frac{1}{2}, \frac{1}{j}, \frac{1}{2n-2j-4}, \frac{3}{2n-2j-4}, \ldots, \frac{2n-2j-7}{2n-2j-4}, \frac{2n-2j-5}{2n-2j-4}\right)
\]
where \( j \) is odd.

Suppose \( H(\alpha', \beta') \) is finite and reducible or primitive irreducible. From Theorem 2.2, we have that for every \( \ell | n - 2 \) that there is only one family up to scalar shift of \((\alpha', \beta')\) for which \( H(\alpha', \beta') \) is reducible. Namely, let \( j, k, \ell \in \mathbb{N} \), with \( (j, k + 1) = 1 \) and \( \ell k = n - 2 \). Denote the roots of \( P_{n-2,k}(z) \) in (2.4) by \( e^{2\pi i a_0}, \ldots, e^{2\pi i a_{n-3}} \). Denote the roots of \( Q_{n-2,k}(z) \) in (2.4) by \( e^{2\pi i b_0}, \ldots, e^{2\pi i b_{n-3}} \). Then the family

\[
\alpha' = (a_0, \ldots, a_{n-3}), \\
\beta' = (b_0, \ldots, b_{n-3})
\]

is the only family up to scalar shift in this case such that \( H(\alpha', \beta') \) is reducible.

The corresponding \((\alpha, \beta)\) for which \( H(\alpha, \beta) \) is signature \((n-1, 1)\) is obtained by adding two \(1/2's\) to \(\alpha'\), and adding two \(0's\) to \(\beta'\), yielding the family \(\mathcal{N}_4\):

\[
(2.8) \quad \alpha = \left( \frac{1}{2}, \frac{1}{2}, a_0, \ldots, a_{n-3} \right), \\
\beta = (0, 0, b_0, b_1, \ldots, b_{n-3}).
\]

This exhausts all of the possibilities and thus we have the statement in the theorem as desired. Since from the previous section we have that any primitive hypergeometric hyperbolic monodromy group is obtained by permuting the coordinates of some interlacing pair \((\alpha', \beta')\), and since there are no sporadic such interlacing pairs in dimensions \( n > 7 \), we have that the families \(\mathcal{M}_1, \mathcal{M}_2, \mathcal{M}_3, \mathcal{N}_1, \mathcal{N}_2, \mathcal{N}_3, \) and \(\mathcal{N}_4\) completely describe the primitive hyperbolic hypergeometric \(H(\alpha, \beta)\)'s in dimension \( n > 9 \).

\[\square\]

2.4. The quadratic form. In this section we calculate the quadratic forms preserved by the primitive hypergeometric hyperbolic monodromy groups described in the previous section. This will be a necessary ingredient in our minimal distance graph method described in Section 4. Recall that the monodromy group \( H = H(\alpha, \beta) \) is generated by two matrices

\[
A := \begin{pmatrix}
0 & 0 & \cdots & 0 & -1 \\
1 & 0 & \cdots & 0 & -a_{n-1} \\
0 & 1 & \cdots & 0 & -a_{n-2} \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
0 & 0 & \cdots & 1 & -a_1
\end{pmatrix}
\quad \text{and} \quad
B := \begin{pmatrix}
0 & 0 & \cdots & 0 & 1 \\
1 & 0 & \cdots & 0 & -b_{n-1} \\
0 & 1 & \cdots & 0 & -b_{n-2} \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
0 & 0 & \cdots & 1 & -b_1
\end{pmatrix}
\]

where the characteristic polynomials of \( A \) and \( B \), \( P(x) := x^n + a_1 x^{n-1} + \cdots + a_{n-1} x + 1 \) and \( Q(x) := x^n + b_1 x^{n-1} + \cdots + b_{n-1} x + 1 \) respectively, are products of cyclotomic polynomials. Denote

\[
(2.9) \quad C := A^{-1}B = \begin{pmatrix}
1 & 0 & \cdots & 0 & -(a_{n-1} + b_{n-1}) \\
0 & 1 & \cdots & 0 & -(a_{n-2} + b_{n-2}) \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
0 & 0 & \cdots & 1 & -(a_1 + b_1) \\
0 & 0 & \cdots & 0 & -1
\end{pmatrix}
\quad \text{and} \quad
v := \begin{pmatrix}
a_{n-1} + b_{n-1} \\
a_{n-2} + b_{n-2} \\
\vdots \\
a_1 + b_1 \\
2
\end{pmatrix}.
\]
The eigenvalues of $C$ are 1 and $-1$ and their geometric multiplicities are $n - 1$ and 1 respectively. The first $n - 1$ elements $e_1, \ldots, e_{n - 1}$ of the standard basis are eigenvectors for the eigenvalue 1 while $v$ is an eigenvector for the eigenvalue $-1$.

**Lemma 2.7.** Let $f \in M_{n \times n}(\mathbb{Z})$. Then $A^t f A = f$ if and only if $\tilde{A}^{i-1} f e_1 = f e_1$ for every $2 \leq i \leq n$ where $\tilde{A} = (A^t)^{-1}$.

**Proof.** The only if part follows from comparing the first $n - 1$ columns of both sides of $\tilde{A} f = f A$. For the if part it is suffices to check that also the last columns of $\tilde{A} f$ and $f A$ are equal. The equalities of the first $n - 1$ columns imply that $\tilde{A}^{i-1} f e_1 = f \tilde{A}^{i-1} e_1$ for every $1 \leq i \leq n - 1$. The characteristic polynomial $P(x)$ of $A$ is also the characteristic polynomial of $\tilde{A}$ since it is a product of cyclotomic polynomials. Thus,

$$f A e_n = f A^n e_1 = -f(a_1 A^{n-1} + \cdots + a_{n-1} A + A)e_1 = -\left(a_1 \tilde{A}^{n-1} + \cdots + a_{n-1} \tilde{A} + \tilde{A}\right) f e_1 = \tilde{A} f A^{n-1} e_1 = \tilde{A} f e_n$$

$\square$

**Lemma 2.8.** Assume that $f \in M_{n \times n}(\mathbb{Z})$ satisfies $A^t f A = f$. Then $B^t f A = f$ if and only if $f e_1$ is Euclidean-orthogonal to $B^{2^{i-1}} v$ for every $2 \leq i \leq n$. In particular, if $A^t f A = f$ and $B^t f B = f$ then $f e_i$ is Euclidean-orthogonal to $v$ for every $1 \leq i \leq n - 1$.

**Proof.** Lemma 2.7 and its analog with respect to $B$ implies that $B^t f B = f$ if and only if $\tilde{A}^{i-1} f e_1 = B^{i-1} f e_1$ for every $2 \leq i \leq n$. As the first row of $\tilde{A} - B$ is $-v^t$ while the other rows are zeros, $f e_1$ must be orthogonal to $v$ (under the usual Euclidean scalar product). For every $i \geq 3$

$$\tilde{A}^{i-1} - B^{i-1} = \tilde{A} (\tilde{A}^{i-2} - B^{i-2}) - (\tilde{B} - \tilde{A}) B^{i-2}$$

so by induction on $i$ we see that $f$ satisfies the required condition if and only if $(\tilde{B} - \tilde{A}) B^{i-2} f = 0$ which is equivalent to $f$ being Euclidean-orthogonal to $B^{2^{i-1}} v$ for every $3 \leq i \leq n$. Finally, if $A^t f A = f$, $B^t f B = f$ then also $C^t f C = C$. Thus, for $1 \leq i \leq n - 1$ we have $v^t f e_i = (C v)^t f C e_i = -v^t f e_i$ so $v^t f e_i = 0$. $\square$

**Proposition 2.9.** Let $A$, $B$, $C$, $P(X)$, $Q(X)$ and $v$ be as above. Assume that the group $H := \langle A, B \rangle$ is primitive. Then:

1. The vectors $v, Bv, \ldots, B^{n-1} v$ are linearly independent and $H = \langle A, B \rangle$ preserves the lattice $L$ spanned by them.
2. There exists a unique (up to a scalar product) non-zero integral quadratic form $(\cdot, \cdot)$ such that $A$ and $B$ belong to its orthogonal group.
3. If the quadratic form is normalized to have $(v, v) = -2$ then $(v, u)$ equals to minus the $n^{th}$-coordinate of $u$ for every $u \in \mathbb{Z}^n$.
4. If the coefficients of $Q(x)$ satisfy $B_i = (-1)^i$ then the matrix representing $f$ w.r.t. $v, Bv, \ldots, B^{n-1} v$ is given by

$$f_{i,j} := \begin{cases} -2 & \text{if } |i - j| = 0 \\ -1 - a_1 & \text{if } |i - j| = 1 \\ -a_k - a_{k-1} & \text{if } |i - j| = k \notin \{0, 1\} \end{cases}$$
Proof. We start by proving the existence part of (2). By Lemma 2.8 there exists a non-zero $f \in M_{n \times n}(\mathbb{Z})$ such that $A^t f A = A$ and $B^t f B = f$. Assume first that $f$ is anti-symmetric so $v^t f v = 0$. Lemma 2.8 implies that $v^t f e_i = 0$ for every $1 \leq i \leq n - 1$. Since $v, e_1, \ldots, e_{n-1}$ span $\mathbb{Q}^n$, the set \{w $\in \mathbb{Q}^n$ $|$ $w^t f w = 0$ for all $u \in \mathbb{Q}^n$\} is a non-trivial proper subspace of $\mathbb{Q}^n$. This subspace is preserved by $H$, a contradiction to the irreducibility of $H$. Thus, $f$ is not anti-symmetric and the quadratic form $(u_1, u_2) := u_1^t (f + f^t) u_2$ has the desired properties. Lemma 2.8 implies that $v^t (f + f^t) = (0 \cdots 0 c)$ for some $c \neq 0$ so (3) holds.

Since $H$ is primitive, every non-trivial normal subgroup of it is irreducible. Thus in order to prove (1) it is enough to show that the normal subgroup $H_r := \langle B^{-i} C B^i \mid i \in \mathbb{Z} \rangle$ preserves the $\mathbb{Z}$-lattice spanned by $v, Bv, \ldots, B^{n-1}v$. Property (3) implies that $Cu = u - 2\frac{(v, u)}{(v, v)} v$ for every $u \in \mathbb{Z}^n$. Since $B$ preserves the quadratic form, $B^{-i} C B^i u = u - 2\frac{(B^{-i} v, u)}{(B^{-i} v, B^{-i} v)} B^{-i} v$ for every $u \in \mathbb{Z}^n$. Thus, $H_r$ preserves the $\mathbb{Z}$-lattice spanned by $v, Bv, \ldots, B^{n-1}v$ and the proof of (1) is complete. The uniqueness part of (2) now follows from (1) together with Lemma 2.8.

For $1 \leq i \leq n - 1$ the $(n - i)$-th and the $(n - i + 1)$-th coordinates of bottom row of $B^t$ are equal to 1 and all the other coordinates of this row are zero. Thus, the last coordinate of $B^t v$ is $a_1 + 1$ if $i = 1$ and $a_i + a_{i-1}$ if $2 \leq i \leq n - 1$. From (3) we get $(v, B^t v) = f_{i,i}$ for every $1 \leq i \leq n$. Property (4) follows from the fact the $f_{i,j}$ depends only on $|i - j|$ since $B$ preserves the quadratic form. □

We now record the invariant quadratic form for two cases that we consider in Section 4.2

Corollary 2.10. Let $(\cdot, \cdot)$ be the normalized quadratic form preserved by $N_1(1, n, n)$. If $1 \leq i, j \leq n$ then

$$(B^t v, B^t v) = \begin{cases} 
-2 & \text{if } |i - j| = 0 \\
-3 & \text{if } |i - j| = 1 \\
-4 & \text{if } |i - j| \geq 2 
\end{cases}$$

Corollary 2.11. Let $(\cdot, \cdot)$ be the normalized quadratic form preserved by $N_1(3, n, n)$. If $1 \leq i, j \leq n$ then

$$(B^t v, B^t v) = \begin{cases} 
-2 & \text{if } |i - j| = 0 \\
-4 & \text{if } |i - j| = 1 \\
-8 & \text{if } |i - j| = 2 \text{ or } |i - j| = n - 1 \\
-11 & \text{if } |i - j| = 3 \text{ or } |i - j| = n - 2 \\
-12 & \text{otherwise}
\end{cases}$$

3. Cartan involutions

3.1. Hyperbolic reflection groups. As noted in the Introduction we make crucial use of Vinberg’s [Vi1], [Vi2] as well as Nikulin’s [N1] results concerning the size of groups generated by hyperbolic reflections. Before reviewing this arithmetic theory we begin with quadratic forms and hyperbolic space over the reals. A non-degenerate real quadratic form $f(x_1, \ldots, x_n)$ with corresponding symmetric bilinear form $(\cdot, \cdot)$ is determined by its signature. Our interest is in the case that $f$ has signature $(-1, 1, \ldots, 1)$, which after a real linear change of variable can be brought to
the form
\begin{equation}
(3.1) \quad f(x_1, \ldots, x_n) = -x_1^2 + x_2^2 + \cdots + x_n^2.
\end{equation}

The null cone $C$ of $f$ is $\{x \mid (x, x) = 0\}$ as depicted in Figure 1.

**Figure 1.**

$\mathbb{R}^n \setminus C$ consists of 3 components, the outside, $(x, x) > 0$, which consists of one component, and the inside, $(x, x) < 0$, which consists of 2 components: $x_1 > 0$ and $x_1 < 0$. The quadrics $(x, x) = k$ where $k < 0$ are two sheeted hyperboloids and either sheet, say the one with $x_1 > 0$ and $k = -2$, can be chosen as a model of hyperbolic $n - 1$ dimensional space (we assume that $n \geq 3$), $\mathbb{H}^{n-1}$. This is done by restricting the line element $ds^2 = -dx_1^2 + dx_2^2 + \cdots + dx_n^2$ to $\mathbb{H}^{n-1}$. The quadrics $(x, x) = k$ with $k > 0$ are one sheeted hyperboloids. If $g \in O_f(\mathbb{R})$, the real orthogonal group of $f$, then $g$ preserves the quadrics, however it may switch the sheets of the two sheeted hyperboloid. If it preserves each of these, then $g$ acts on $\mathbb{H}^{n-1}$ isometrically, while if $g$ switches the sheets then $-g$ acts isometrically on $\mathbb{H}^{n-1}$. In either case we obtain an induced isometry. Of particular interest to us are linear reflections of $\mathbb{R}^n$ given by $v$’s with $(v, v) \neq 0$ (i.e. not on the null cone). For such a $v$ denote by $r_v$ the linear transformation
\begin{equation}
(3.2) \quad r_v(y) = y - \frac{2(v, y)}{(v, v)} v.
\end{equation}

It is easy to see that $r_v \in O_f$, that it is an involution, and that it preserves the components of the complement of the light cone if $(v, v) > 0$, and switches them if $(v, v) < 0$. In the first case, the induced isometry of $\mathbb{H}^{n-1}$ is a hyperbolic reflection. The fixed point set of $r_v$ in $\mathbb{R}^n$ is $v^\perp = \{y \mid (v, y) = 0\}$ and this intersects $\mathbb{H}^{n-1}$ in an $n-2$-dimensional hyperbolic hyperplane and the induced isometry is a (hyperbolic) reflection about this hyperplane. In the second case, $(v, v) < 0$, the induced isometry $-r_v$ fixes the line $\ell_r = \{\lambda v \mid \lambda \in \mathbb{R}\}$ and this line meets $\mathbb{H}^{n-1}$ in a point $p_v$. The induced isometry of $\mathbb{H}^{n-1}$ in this case inverts geodesics in $p_v$ and is a Cartan involution. These two involutive isometrics of $\mathbb{H}^{n-1}$ are quite different. In the case of a discrete group of motions generated hyperbolic reflections, there is a canonical fundamental domain, namely the connected components of the complement of the hyperplanes corresponding to all the reflections. This is the
starting point to Vinberg’s theory of reflective groups. For groups generated by Cartan involutions there is no apparent geometric approach.

We turn to the arithmetic theory. Let $L \subseteq \mathbb{Q}^n$ be a quadratic lattice, that is a rank $n$ $\mathbb{Z}$-module equipped with a non-degenerate integral symmetric bilinear form $(\ , \ )$, whose associated quadratic form $f(x) = (x, x)$ is rational. The dual lattice $L^*$ of $L$ is given by

$$L^* = \{ x \in \mathbb{Q}^n \mid (x, y) \in \mathbb{Z} \text{ for all } y \in L \}.$$ 

It contains $L$ as a finite sublattice and the invariant factors of $L$ are defined to be the invariants of the torsion module $L^*/L$. The product of these invariants is equal to $\pm d(L)$, where $d(L)$ is the discriminant of $L$ (that is $\det(F)$ where $F$ is an integral matrix realization of $f$). We assume that $L \otimes \mathbb{R}$ is hyperbolic and of signature $(-1,1,\ldots,1)$. The $\mathbb{Z}$ analogue of the null cone is $C(L) = \{ x \in L \mid (x, x) = 0 \}$ and that of the quadrics is $V_k(L) := \{ x \in L \mid (x, x) = k \}$ for $k \in \mathbb{Z}$, $k \neq 0$. We assume throughout that $f$ is isotropic over $\mathbb{Q}$ which means that $C(L) \neq \emptyset$ (and is in fact infinite). The group of integral automorphs of $L$ is denoted by $O(L)$ or $O_f(\mathbb{Z})$. A primitive vector $v$ in $V_k(L)$ is called a $k$-root if $\frac{2v}{k} \in L^*$. In this case the linear reflection $r_v$ of $\mathbb{Q}^n$ given by $(3.2)$ is integral and lies in $O(L)$. For $k = \pm 1$ or $\pm 2$, $\frac{2v}{k}$ is always in $L^*$ and we will have occasions where $k = 4$ yields root vectors as well. As discussed above, the root vectors with $k > 0$ induce hyperbolic reflections on $\mathbb{H}^{n-1}_f$ (which we choose to be one of the components of $V_{-2}(\mathbb{R}) = \{ x \in L \otimes \mathbb{R} \mid (x, x) = -2 \}$) while for $k < 0$ they induce Cartan involutions.

The Vinberg reflective group $R(L)$ is the subgroup of $O(L)$ generated by all hyperbolic reflections coming from root vectors with $k > 0$. It is plainly a normal subgroup of $O(L)$ and the main result in [Vi2] asserts that if $n \geq 30$ then $|O(L)/R(L)| = \infty$. Vinberg’s proof is based on studying the fundamental domain in $\mathbb{H}^{n-1}$ of $R(L)$ and relating it to the cusps of $O(L)\backslash \mathbb{H}^{n-1}$ which correspond to null vectors $w \in C(L)$. In particular it uses the assumption that $f$ is isotropic.

Nikulin’s results [Ni1] are concerned with the case that $L$ is even, that is $(x, x) \in 2\mathbb{Z}$ for all $x \in L$, and the subgroup $R_2(L)$ generated by all the 2-root vectors in $L$ (note he chooses $f$ to have signature $(1,-1,-1,\ldots,-1)$ so that his 2-root vectors are our 2-root vectors). $R_2(L)$ is a subgroup of $R(L)$ and it is also normal in $O(L)$. For these he gives a complete classification of all $L$’s for which $O(L)/R_2(L)$ is finite. There are only finitely many such and for $n \geq 5$ the list is quite short. $L$ is called two elementary if $L^*/L$ is $(\mathbb{Z}/2\mathbb{Z})^a$ for some $a$. If $L$ is not two elementary and $n \geq 5$ and odd (the last condition on $n$ is what is of interest to us for our applications) then $|O(L)/R_2(L)| = \infty$ unless $L$ is isomorphic to $U \oplus K$ and $K$ is one of

$$A_{3}, A_{1} \oplus A_{2}, A_{1} \oplus A_{2}^{2}, A_{1}^{2} \oplus A_{3}, A_{2} \oplus A_{3}, A_{1} \oplus A_{4},$$

$$A_{5}, D_{5}, A_{7}, A_{3} \oplus D_{4}, A_{2} \oplus D_{5}, D_{7}, A_{1} \oplus E_{8}, A_{3} \oplus E_{8}$$

or $L$ is isomorphic to

$$U(4) \oplus A_{1}^{3}, (-2^k) \oplus D_{4} \text{ for } k = 2, 3, 4, \text{ or } (-2, 3) \oplus A_{2}^{2}.$$ 

Here the positive definite (2-reflective) lattices $A_n$, $D_n$, $E_n$ are the standard ones (see [C-S]) while $U = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$ and $U(4) = \begin{bmatrix} 0 & 4 \\ 4 & 0 \end{bmatrix}$. 

As a consequence unless $L$ is two elementary or its invariant factors are among the list below, $|O(L)/R_2(L)| = \infty$.

| Dimesion | Factors                                      |
|----------|---------------------------------------------|
| 5        | $2 \cdot 3, 4, 2 \cdot 3^2, 4^2 \cdot 2^4, 4 \cdot 4, 8, 4 \cdot 16$ |
| 7        | $2 \cdot 3 \cdot 3, 2 \cdot 2 \cdot 4, 3 \cdot 4, 2 \cdot 5, 3 \cdot 2, 4$ |
| 9        | $8, 4 \cdot 4, 3 \cdot 4, 4 \cdot 3$          |
| 11       | none                                         |
| 13       | $4$                                          |
| $\geq 15$| none                                         |

Table 1.

### 3.2. Pseudo-reflections and Cartan involutions.

The almost interlacing condition on the $(\alpha, \beta)$’s ensures that $H(\alpha, \beta)$ lies in an orthogonal group of a quadratic form $f$ of signature $(p, q)$, i.e. $(1, 1, \ldots, 1, -1, -1, \ldots, -1)$ with $|p - q| = 2$. The form $f$ is unique up to a scalar multiple and we normalize $f$ so that $f(v, v) = -2$ where $v$ is the vector given in (2.9). In order to determine what type of involution these critical pseudo-reflections $r_v$ induce on hyperbolic space we need to determine the number $p - q$, when $f$ is so normalized. This can be done by keeping track of the signs in the calculations in Proposition 4.4 and Theorem 4.5 in [B-H]. With $u = v$ in equation (4.5) in [B-H] (note there is a misprint there: it should be $D(x)$ rather than $D(u)$), $\eta = 1$, and $c = -1$ we have

$$D(x) = (h_1 - I)x = f(x, u)u$$

Hence from (4.7) of [B-H] we have that for their orthogonal basis $u_j$ of $\mathbb{R}^n$, $j = 1, 2, \ldots, n$,

$$f(u_j; u_j) = i \exp \left[ 2\pi i \left( \frac{\beta_1 + \beta_2 + \beta_n - \alpha_1 - \alpha_2 - \alpha_n}{2} \right) \right] \cdot 2 \sin \pi (\beta_j - \alpha_j) \prod_{k \neq j} \frac{\sin \pi (\beta_k - \alpha_j)}{\sin \pi (\alpha_k - \alpha_j)}$$

where we have assumed for simplicity that the $\alpha_k$’s and $\beta_k$’s are distinct.

To determine the signs there are two cases:

1. $\alpha_1 = 0$:

   We write $(\alpha_1, \alpha_2, \ldots, \alpha_n)$ as $(0, t_1, \ldots, t_m, t_{-m}, \ldots, t_{-1})$ with $2m + 1 = n$.

   Here $t_j = 1 - t_{-j}$ for $j = 1, \ldots, m$ (which corresponds to self duality of $\alpha, \beta$).

   Writing $\beta$’s similarly as $(\beta_1, \ldots, \beta_n) = (s_1, s_2, \ldots, s_m, \frac{1}{2}, s_{-m}, \ldots, s_{-1})$ with $s_j = 1 - s_{-j}$ for $j = 1, \ldots, m$, $2m + 1 = n$, we find that for the $\alpha$’s and $\beta$’s to almost interlace the configuration must be
The factor $i \exp[\pi/4]$ in (3.4) is therefore $i \exp[2\pi i/4] = -1$ and hence $f(u_1, u_1) < 0$. Between every pair $\alpha_j, \alpha_{j+1}$ but the first one, there are one or three $\beta$’s and hence $f(u_2, u_2) > 0, f(u_3, u_3) > 0, \ldots, f(u_n, u_n) > 0$. That is $f$ has signature $(1, 1, \ldots, 1, -1)$.

(2) $\beta_1 = 0$:
Again we can write $\alpha = (\alpha_1, \ldots, \alpha_n) = (t_1, \ldots, t_m, t_{m+1}, \ldots, t_{n-1})$ and $\beta = (\beta_1, \ldots, \beta_n) = (0, s_1, s_2, \ldots, s_m, s_{-m}, s_{-m-1}, \ldots, s_{-n})$, with $t_{m+1} = 1 - t_m$ and $s_{-m} = 1 - s_m$.

To almost interlace we must have the configuration

Hence the factor $i \exp[\pi/4]$ in (3.4) is this time $i \exp[-2\pi i/4] = 1$. Hence $f(u_1, u_1) > 0$, as are $f(u_2, u_2), \ldots, f(u_m, u_m)$. Since there are no $\beta$’s in $(t_m, 1/2)$ and $(1/2, t_{m+1})$, we have that $f(u_m, u_m) < 0$ and $f(u_{m+1}, u_{m+1}) > 0$ as are the rest of the $f(u_j, u_j)$ for $m + 1 < j \leq n$. Hence the signature of $f$ is again $(1, 1, \ldots, 1, -1)$.

Thus in all cases (that is the two above as well as those where some of the $\alpha$’s coincide in which case one deduces the signs by a limiting argument) we have that if $f$ is normalized so that $f(v, v) = -2$ then $f$ has signature $(1, 1, \ldots, 1, -1)$. In particular $v$ always lies inside the null cone and $r_v$ induces a Cartan involution. This is in sharp contrast to the involutions in $O_f(\mathbb{Z})$ that arise in the theory of $K3$-surfaces in [N1] and [Vi1] which in our normalization have $f(v, v) = 2$ and hence induce hyperbolic reflections.

3.3. An example of a non-thin Cartan subgroup. The goal of this short section is to give an example of a hyperbolic lattice $O(L)$ whose reflection group $R_2(L)$ is thin while the Cartan subgroup $R_{-2}(L)$ is of finite index.

Define a quadratic form

\[
(3.5) \quad f(x_1, x_2, x_3, x_4) := 2x_1^2 + 5x_2^2 + 10x_3^2 - x_4^2
\]

and let $O(L)$ be the orthogonal group of $f$ over $\mathbb{Z}$. The following facts can be found in pages 474–477 of [E-G-M].

Fact 1 $R_2(L)$ is thin.
Fact 2 $R_2(L)$ is generated by 4 reflections $\sigma_1, \sigma_2, \sigma_3, \sigma_4$ and $\sigma_2, \sigma_3$ belong to the center of $R_2(L)$.

Thus, $R_2(L)$ is isomorphic to a quotient of $C_2 \times C_2 \times D_\infty$ where $D_\infty$ is the infinite dihedral group. In particular any element of $R_2(L)$ which has infinite order generates a finite index subgroup.
Fact 3 $\Omega(L)$ is isomorphic to the semidirect product $R_2(L) \rtimes D_\infty$. Under this isomorphism $D_\infty$ is generated by the following two involutions:

$$g := \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & -2 & -2 & 1 \\ 0 & -1 & -3 & 1 \\ 0 & -5 & -10 & 4 \end{pmatrix}, \quad h := \begin{pmatrix} -2 & 0 & -5 & 2 \\ 0 & 1 & 0 & 0 \\ -1 & 0 & -6 & 2 \\ -4 & 0 & -20 & 7 \end{pmatrix}.$$

We start by showing that $R_{-2}(L)$ is not contained in $R_2(L)$. A direct computation shows that $\mathbb{Q}^4$ is decomposed as $V^+ \oplus V^-$ where $V^+ := \{ v \in \mathbb{Q}^4 \mid hv = v \}$ and $V^- := \{ v \in \mathbb{Q}^4 \mid hv = -v \}$. In addition $u := (1 \ 1 \ 1 \ 4)^t \in V^+$ satisfies $f(u) = 1$ so the reflection $r_u$ in integral. Let $w$ be an element of $V^+$ orthogonal to $u$. Since $f|_{V^+}$ is not positive definite, $(w, w) < 0$. Notice that:

$$\forall v \in V^-, \ hr_u(v) = -v,$$

$$hr_u(u) = -u,$$

$$hr_u(w) = w.$$

Thus, the Cartan involution $r_u = hr_u$ is integral and does not belong to $R_2(L)$.

Denote $r_1 := r_w$, $r_2 := r_w^{gh}$ and \( \Lambda := \langle r_1, r_2 \rangle \). The Cartan involutions $r_1$ and $r_2$ have distinct images in $\Omega(L)/R_2(L) \simeq D_\infty$. Thus, $\Lambda R_2(L)/R_2(L)$ is of finite index in $\Omega(L)/R_2(L)$. In other words $R_2(L)\Lambda$ is of finite index in $\Omega(L)$.

By the second isomorphism theorem,

$$\Lambda/(\Lambda \cap R_2(L)) \simeq \Lambda R_2(L)/R_2(L).$$

Every proper quotient of $D_\infty$ is finite so $\Lambda \cap R_2(L)$ is trivial. In particular, the group generated by $\Lambda$ and $R_2(L)$ is in fact a semidirect product. Assume for the moment that $\sigma_1$ not commute with $r_1$. Then $r_3 := \sigma_1 r_1 \sigma_1 \in R_2(L)\Lambda$ is a Cartan involution different form $r_1$ so $r_1 r_3$ has infinite order. Moreover, since $R_2(L)$ is normal in $\Omega(L)$, $r_1 r_3 \in R_2(L)$ so by Fact 2 the group generated by $\langle r_1, r_3 \rangle$ has finite index in $R_2(L)$. Altogether we get that $\langle r_1, r_2, r_3 \rangle$ has finite index in $R_2(L)\Lambda$ and in $\Omega(L)$.

Finally, $\sigma_1$ and $r_1$ do not commute since

$$r_1 := \begin{pmatrix} -6 & -10 & -25 & 10 \\ -4 & -9 & -20 & 8 \\ -5 & -10 & -26 & 10 \\ -20 & -40 & -100 & 39 \end{pmatrix}, \quad \sigma_1 := \begin{pmatrix} -1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}.$$

4. The minimal distance graph and thin families

4.1. The distance graph. In this section we derive a sufficient condition for a subgroup $\Delta$ of $\Omega(L)$ which is generated by Cartan involutions, to have finite image in $\Omega(L)/R_k(L)$ with $k = 2$ or 4. Here $L$ is an integral quadratic lattice of signature $(-1, 1, \ldots, 1)$ and our notation is the same as in Section 3. We say $L$ is even if $(x, x) = f(x)$ is even for all $x \in L$ but $f(x, y)$ is odd for some $x, y \in L$. If the latter fails, that is $f(x, y)/2$ is integral for all $x, y \in L$ and $f(x, x)/2$ is odd for some
Proof. Part (1) of both (i) and (ii) is immediate. As for parts (2) and (3) of (i), note that since Lemma 4.1, if \( r \) only if \( k \) check directly (or by the classification in \([S_2]\) equivalent to \(-f \) while if \( f \) is even we will make use of the hyperbolic reflection group \( R_2(L) \), while if \( f \) is odd we will use \( R_1(L) \). The following diophantine lemma is crucial for what follows.

**Lemma 4.1.** If \( u, w \in \mathbb{Z}^n \) satisfy \((u, u) = (w, w) = -2 \) and \((u, w) = -3 \) then

(i) If \( f \) is even and \( u \) and \( w \) are in \( V_2(L) \) with \((u, w) = -3 \) then

1. \((u - w, u - w) = (u - 2w, u - 2w) = 2.\)
2. \( r_u r_w = r_{u-w} r_{u-2w}. \)
3. \( r_{u-w}(u) = w. \)

(ii) If \( f \) is odd (i.e. \((u, w)/2 \) is integral and odd) and \( u \) and \( w \) are in \( V_2(L) \) with \((u, w) = -4 \) then

1. \((u - w, u - w) = (u - 3w, u - 3w) = 4.\)
2. \( r_u r_w = r_{u-w} r_{u-3w}. \)
3. \( r_{u-w}(u) = w. \)

Proof. Part (1) of both (i) and (ii) is immediate. As for parts (2) and (3) of (i), note that since \( r_u, r_w, r_{u-w}, \) and \( r_{u-2w} \) all fix the orthogonal complement \( \langle u, w \rangle \) of the span of \( u \) and \( w \), it suffices to check (2) on the two dimensional space \( \langle u, w \rangle \). That is to check the identity on \( u \) and \( w \). Now a direct calculation shows that

\[
\begin{align*}
r_u(u) &= -u, \quad r_u(w) = w - 3u \\
r_w(u) &= u - 3w, \quad r_w(w) = -w \\
r_{u-w}(u) &= w, \quad r_{u-w}(w) = u
\end{align*}
\]

and

\[
\begin{align*}
r_{u-2w}(u) &= -3u + 8w, \quad r_{u-2w}(w) = -u + 3w
\end{align*}
\]

Hence with respect to the basis \( u, w \) of \( \langle u, w \rangle \) we have

\[
\begin{align*}
&\quad \begin{bmatrix}
-1 & -3 \\
0 & 1
\end{bmatrix}, \quad
\begin{bmatrix}
1 & 0 \\
-3 & -1
\end{bmatrix}, \quad
\begin{bmatrix}
0 & 1 \\
1 & 0
\end{bmatrix}, \quad
\begin{bmatrix}
-3 & -1 \\
8 & 3
\end{bmatrix} \\
&\quad \begin{bmatrix}
-1 & -4 \\
0 & 1
\end{bmatrix}, \quad
\begin{bmatrix}
1 & 0 \\
-4 & -1
\end{bmatrix}, \quad
\begin{bmatrix}
0 & 1 \\
1 & 0
\end{bmatrix}, \quad
\begin{bmatrix}
-4 & -1 \\
15 & 4
\end{bmatrix}
\end{align*}
\]

and parts (2) and (3) of (i) follow. Similarly for part (2) and (3) of (ii). This time in the basis \( u, w \) of \( \langle u, w \rangle \) we have that

\[
\begin{align*}
r_u &= \begin{bmatrix}
-1 & -4 \\
0 & 1
\end{bmatrix}, \quad
r_w = \begin{bmatrix}
1 & 0 \\
-4 & -1
\end{bmatrix}, \quad
r_{u-w} = \begin{bmatrix}
0 & 1 \\
1 & 0
\end{bmatrix}, \quad
r_{u-3w} = \begin{bmatrix}
-4 & -1 \\
15 & 4
\end{bmatrix}
\end{align*}
\]

and hence (2) and (3) of (ii) hold. \( \square \)

**Remark 4.2.** The factorization of \( r_u r_w \) as a product of two integral hyperbolic reflections in part (2) of both (i) and (ii) in the previous lemma has its source in the binary integral quadratic forms \( f_1 = -2x^2 - 6xy - 2y^2 \) and \( f_2 = -2x^2 - 8xy - 2y^2 \) being reciprocal in that \( f_1 \) and \( f_2 \) are integrally equivalent to \(-f_1\) and \(-f_2\), respectively. As shown in \([S_2]\) this property is quite rare and one can check directly (or by the classification in \([S_2]\)) that \( x^2 + kxy + y^2 \) where \( k \geq 3 \) is reciprocal if and only if \( k = 3 \) or \( 4 \) and these two cases correspond to \( f_1 \) and \( f_2 \) above.
Lemma 4.1 leads us to the definition of the minimal distance graph associated with $f$.

**Definition 4.3.** The minimal distance graph $X_f$ of $f$ is the graph with vertex set $V_{-2}(L)$ (i.e. the set of Cartan involutions coming from length $-2$ roots) and edge sets

$$E_f := \{\{u, w\} \mid (u, w) = -3\} \text{ if } f \text{ is even}$$

and

$$E_f := \{\{u, w\} \mid (u, w) = -4\} \text{ if } f \text{ is odd}.$$  

The name minimal distance graph comes from the fact that if $u$ and $w$ are in $V_{-2}(L)$ then as points of hyperbolic space $\mathbb{H}^{n-1} \cong V_{-2}(L) \otimes \mathbb{R}$ the distance from $u$ to $w$ is equal to $\cosh^{-1}\left(\frac{-(u, w)}{2}\right)$.

Hence if $(u, w) = -3$ when $f$ is even or $-4$ when $f$ is odd, then clearly the integrality of $(\ , \ )$ on $L$ implies that $(u, w)$ has the minimal admissible distance as members of $V_{-2}(L)$.

**Proposition 4.4.** Let $S$ be a connected component of $X_f$, then the image of $(r_u \mid u \in S)$ in $O(L)/R_2(L)$ (respectively $O(L)/R_4(L)$) is of order at most two.

**Proof.** Let $w_1, \ldots, w_m$ be a path in $X_f$. We have

$$r_{w_1}r_{w_m} = (r_{w_1}r_{w_2})(r_{w_2}r_{w_3}) \cdots (r_{w_{m-1}}r_{w_m}),$$

which according to Lemma 4.1 in the case that $f$ is even (and a similar conclusion when $f$ is odd) gives

$$r_{w_1}r_{w_m} = (r_{w_1-w_2}r_{w_1-2w_2})(r_{w_2-w_3}r_{w_2-2w_3}) \cdots (r_{w_{m-1}-w_m}r_{w_{m-1}-2w_m}).$$

Now the elements in each parenthesis above lie in $R_2(L)$, and hence $r_{w_1}r_{w_m} \in R_2(L)$ from which the proposition follows directly. \qed

Our certificate for a subgroup $\Delta$ of $O(L)$ generated by Cartan roots $v$ in $V_{-2}(L)$ to be infinite index in $O(L)$ is now clear. If the generators of $\Delta$ all lie in the same connected component of $X_f$ then the image of $\Delta$ in $O(L)/R_k(L)$ where $k = 2$ or 4 is finite. Hence if $|O(L)/R_k(L)| = \infty$ then $\Delta$ is thin.

The structure of the graph $X_f$ can be determined both theoretically and algorithmically. This is based on Vinberg’s theory (see [Vi1] and [Vi2] for a discussion) of finitely generated hyperbolic reflection groups. Specifically, we make use of the following propositions.

**Proposition 4.5.** For every $1 \leq i \leq k$ let $w_i \in \mathbb{Z}^n$ with $(w_i, w_i) = 2$ and denote $\Pi_i := \{x \in \mathbb{H}^{n-1} \mid (x, w_i) > 0\}$ and $\bar{\Pi}_i := \{x \in \mathbb{H}^{n-1} \mid (x, w_i) \geq 0\}$. Assume that:

- $\cap_{1 \leq i \leq k} \Pi_i \neq \emptyset$
- For every $1 \leq j \leq i, \cap_{1 \leq i \neq j \leq k} \bar{\Pi}_i$ is not contained in $\bar{\Pi}_j$

Then $\cap_{1 \leq i \neq j \leq k} \Pi_i$ is a fundamental domain for the action of the reflection group $(r_{w_i} \mid 1 \leq i \leq k)$ on the hyperbolic space $\mathbb{H}^{n-1}$.

**Proposition 4.6.** Let $u$ be a vertex of $X_f$ and let $u_1, \ldots, u_k$ be its neighbors. Denote $w_i := u - u_i$ and let $G := \{r_{u-u_i} \mid 1 \leq i \leq k\}$ then the connected component of $X_f$ containing $u$ is isomorphic to the Cayley graph $\text{Cay}(G, S)$ where $S := \{r_{w_i} \mid 1 \leq i \leq k\}$.
Proof. Lemma \[\text{1.1}\] shows that the $r_{w_i}$'s are indeed reflections. It is clear that $O_f(\mathbb{Z})$ acts by graph automorphisms on $X_f$ and our first task is to show that $G \leq O_f(\mathbb{Z})$ acts transitively on $T_u$, the connected component containing $u$. The proof is by induction on the distance from $u$ (with respect to the graph metric). The induction basis follows from Lemma \[\text{4.1}\] which says that $r_{w_i}(u) = u_i$ for $1 \leq i \leq k$. Note that the induction basis also implies that $G$ preserves $T_u$ since $G$ permutes the connected components of $X_f$ and sends at least one vertex of $T_u$ into $T_u$. Let $u^* \in T_u$ with $\text{dist}_{X_f}(u, u^*) = m > 1$. Pick $\bar{u} \in D_u$ with $\text{dist}_{X_f}(u, \bar{u}) = m - 1$ and $\text{dist}_{X_f}(u^*, \bar{u}) = 1$. By the induction hypothesis there exists $g \in G$ such that $g(\bar{u}) = u$ and so $g(u^*) = u_j$ for some $1 \leq j \leq k$. Thus $u^* = g^{-1}r_{w_j}(u)$ and the induction is complete.

Next, we want to prove that the stabilizer $\text{Stab}_G(u)$ is trivial. This will follow once we show that $D := \cap_{1 \leq i \neq j \leq k} \Pi_i$ is a fundamental domain for $G$ and that $u$ belongs to the interior $D^0 := \cap_{1 \leq i \leq k} \Pi_i$ of the fundamental domain (we regard $u$ both as a vertex of $X_f$ and as a point in $\mathbb{H}^{n-1}$). For every $1 \leq i \leq k$, $(u, w_i) = 1$ so $u \in D^0$. Fix $1 \leq j \leq k$. If $1 \leq i \neq j \leq k$ then $(w_i, u_j) = (u, u_j) - (u, u_j) \geq 0$ so $u_j \not\in D$. Since $D$ is convex, every point in the interior of the geodesic form $u$ to $u_j$ belongs to $D^0$. The midpoint of this geodesic belongs to the hyperplane $\{x \in \mathbb{H}^{n-1} \mid (w_j, x) = 0\}$ and so $\cap_{1 \leq i \neq j \leq k} \Pi_i$ is not contained in $\Pi_j$. Proposition \[\text{4.5}\] now implies that $D$ is a fundamental domain for $G$.

We now have an bijective map $g \mapsto g(u)$ from the vertices of the Cayley graph to the vertices of $T_u$. In fact, this map is an isomorphism of graphs. Two vertices $g, h \in G$ are connected in $\text{Cay}(G, S)$ if and only if $g = hr_{w_i}$ for some $1 \leq i \leq k$. On the other hand, every neighbor of $u$ in $X_f$ is of the form $u_i = r_{w_i}(u)$ for some $1 \leq i \leq k$. Since $G$ acts by graph automorphisms on $X_f$, the neighbors of $g(u)$ in $X_f$ are exactly the elements $g r_{w_i}(u)$ for $1 \leq i \leq k$. \[\square\]

Computational algorithm Using Proposition \[\text{4.5}\] and the proof of Proposition \[\text{4.6}\] we can describe a very simple algorithm for deciding if two vertices $u, \bar{u} \in X_f$ belong to the same connected component. With the notation of the proof of Proposition \[\text{4.6}\] we have to decide if $\bar{u} \in T_u$ which is equivalent to the existence of $g \in G$ for which $g(\bar{u}) = u$. If $\bar{u} \not\in D$ then there is $1 \leq i \leq k$ such that $u$ and $\bar{u}$ lies of different sides of the hyperplane $\{x \in \mathbb{H}^{n-1} \mid (x, w_i) = 0\}$ so $\text{dist}(u, r_{w_i} u) < \text{dist}(u, \bar{u})$. Since the set $\{\text{dist}(u, u^*) \mid u^* \in X_f\}$ is discrete, after a finite number of steps we find an element $g \in G$ such that $g(\bar{u}) \in D$. If $g(\bar{u}) = u$ then $u$ and $\bar{u}$ are in the same connected component. If $g(\bar{u}) \neq u$ then since $u$ belongs the interior of the fundamental domain $D$, $h(\bar{u}) \neq u$ for every $h \in G$ so $u$ and $\bar{u}$ do not belong to the same connected component.

4.2. Thin Families. Using the minimal distance graph and the results reviewed in Section \[\text{3}\] we apply our thinnest certificate to various hyperbolic hypergeometric monodromy groups. Recall that every $H = H(\alpha, \beta)$ is generated by two matrices $A, B \in \text{GL}_n(\mathbb{Z})$ for some odd $n \in \mathbb{N}$. Moreover, there is an integer quadratic form $(u_1, u_2) = u_1^t f u_2$ of signature $(n - 1, 1)$ preserved by $H$. The matrix $C := A^{-1} B$ has an eigenvalue $-1$ of algebraic multiplicity 1 with a corresponding eigenvector $v \in \mathbb{Z}^n$. The elements $v, B v, \ldots, B^{n-1} v$ are linearly independent and the $\mathbb{Z}$-lattice $L$ they span is preserved by $H$. Proposition \[\text{2.9}\] implies we can normalize $f$ to have $(v, v) = -2$ and still be integral on $L$. The group $H$ is of infinite index in the integral orthogonal group of the original form if and only if its restriction to $L$ is of infinite index in the integral orthogonal group of the normalized
form. Thus by restricting to $L$, we can assume from now that $f$ is normalized so $(v, v) = -2$ and $-C$ is a Cartan involution. If $B$ has finite order then the group $\langle B^iCB^{-i} \mid i \in \mathbb{N} \rangle$ is a finite index normal subgroup of $H$. Thus, $H$ is thin if and only if

$$H_r := \langle B^i(-C)B^{-i} \mid i \in \mathbb{Z} \rangle$$

is thin in $O_f(Z)$. The advantage in considering $H_r$ is clear, this group is generated by Cartan involutions so we can apply Proposition 4.4. We begin by noting the following.

**Lemma 4.7.** If $v$ and $Bv$ belong to same component of $X_f$ then $H$ is thin.

**Proof.** The group $H_r$ is generated by the set of Cartan involutions $\{r_{B^i} \mid i \in \mathbb{Z}\}$. Since $B$ preserves $f$, if $v$ and $Bv$ belong to the same connected component then also $B^iB^{-i} = B^iB^{-i}v$ belong to the same connected component for every $i \in \mathbb{N}$. Thus, $\{r_{B^i} \mid i \in \mathbb{Z}\}$ is contained in one connected component so $H_r$ is thin by Proposition 4.4. Hence, $H$ is thin by the above paragraph. \qed

We now prove the following.

**Theorem 4.8.** The following subfamilies of hyperbolic hypergeometric monodromy groups are thin ($n$ is always odd):

1. $\mathcal{N}_1(1, n, n), n > 3$
   \[\alpha = (0, \frac{1}{n+1}, \ldots, \frac{-1}{2(n+1)}, \frac{n+3}{2(n+1)}, \ldots, \frac{n+1}{n+1}), \beta = (\frac{1}{2}, \frac{1}{n}, \ldots, \frac{-1}{n})\]
2. $\mathcal{M}_1(1, n), n > 3$
   \[\alpha = (0, \frac{1}{2n}, \ldots, \frac{n-3}{2n}, \frac{n+1}{2n}, \ldots, \frac{n+3}{2n}), \beta = (\frac{1}{2}, \frac{1}{n}, \ldots, \frac{n+1}{n})\]
3. $\mathcal{N}_1(1, 1, n), n > 30$
   \[\alpha = (0, \frac{1}{2n}, \ldots, \frac{n-3}{2n}, \frac{n+1}{2n}, \ldots, \frac{n+3}{2n}), \beta = (\frac{1}{2}, \frac{1}{n}, \ldots, \frac{n+1}{n})\]
4. $\mathcal{M}_2(n - 2, n), n > 3$
   \[\alpha = (0, \frac{1}{2n-2}, \ldots, \frac{n-3}{2n-2}, \frac{n+1}{2n-2}, \ldots, \frac{n+3}{2n-2}), \beta = (0, 0, 0, \frac{1}{n}, \ldots, \frac{n+1}{n})\]
5. $\mathcal{M}_2((n - 1)/2, n), n > 30, n \neq 1 \mod 4$
   \[\alpha = (\frac{1}{2}, \frac{1}{2n-2}, \ldots, \frac{n-3}{2n-2}, \frac{n+1}{2n-2}), \beta = (0, 0, 0, \frac{1}{n}, \ldots, \frac{n-3}{n})\]
6. $\mathcal{N}_2(1, 1, n), n > 30$
   \[\alpha = (0, \frac{1}{2n-2}, \ldots, \frac{n-3}{2n-2}, \beta = (\frac{1}{2}, \frac{1}{2}, \ldots, \frac{n-3}{n}, \frac{n+1}{n})\]
7. $\mathcal{N}_2(n - 1, 1, n), n > 3$
   \[\alpha = (0, \frac{2}{n}, \ldots, \frac{n-1}{n}), \beta = (\frac{1}{2}, \frac{1}{2}, \ldots, \frac{n-3}{n}, \frac{n+1}{n}, \ldots, \frac{n-3}{n})\]
8. $\mathcal{N}_1(n, n), n > 3$ and $(n + 1, 3) = 1$
   \[\alpha = (0, \frac{1}{n+1}, \ldots, \frac{-1}{2(n+1)}, \frac{n+3}{2(n+1)}, \ldots, \frac{n+1}{n+1}), \beta = (\frac{1}{2}, \frac{1}{3}, \ldots, \frac{n-3}{n-2})\]

Note that in the cases above where we require $n > 30$ the form fixed by the group is odd, and we appeal to Vinberg \[Vi1\] to derive thinness. In the cases where we require $n > 3$, the fixed form is even and we appeal to Nikulin \[Ni\] to conclude the group is thin by checking using a computer that none of the $n < 30$ cases are two elementary or belong to the lists at the end of Section 3.1.
Proof. (1):
Corollary 2.10 shows that \((v, Bv) = -3\) and we can apply Lemma 4.7.

(2):
In this case, we have that the generators of \(H(\alpha, \beta)\) are as in (2.1) with
\[
A_i = \begin{cases} 
0 & \text{for } 2 \leq i \leq n - 2 \\
1 & \text{otherwise}
\end{cases}
\]
and
\[
B_n = -1 \\
B_i = (-1)^i \cdot 2 & \text{for } i < n.
\]

Therefore the eigenvector of \(C = A^{-1}B\) with eigenvalue 1 is thus \(v = (3, 2, 2, \ldots, 2, -1, 2)^t\). Note that the order of \(B\) is \(2n\).

The quadratic form \(f\) fixed by \(A\) and \(B\) in the basis \(\{v, Bv, \ldots, B^{n-1}v\}\) has \(ij\)th entry 3 if \(|i - j| = 1\), and by Lemma 4.1 the basis vectors are thus in one connected component of \(X_f\) since \(e_i^t f e_{i+1} = 3\) for all \(1 \leq i \leq n - 1\). To see this, note that the \(n\)th row of \(B^m\) is of the form
\[
(b_1 \ b_2 \ \cdots \ b_n)
\]
where \(b_i = 0\) for \(i \leq n - m - 1\), \(b_{n-m} = 1\), and \(b_i = 2\) for \(i > n - m\). Therefore in particular the \(n\)th entry of \(Bv\) is 3 as desired.

(3):
In this case the generators of \(H(\alpha, \beta)\) are as in (2.1) with
\[
A_i = \begin{cases} 
2 & \text{for } 1 \leq i \leq n - 1 \\
1 & \text{for } i = n
\end{cases}
\]
and
\[
B_n = -1 \\
B_i = (-1)^i \cdot 2 & \text{for } i < n.
\]

The eigenvector of \(C = A^{-1}B\) with eigenvalue 1 is thus \(v = (4, 0, 4, 0, \ldots, 4, 0, 2)^t\). The order of \(B\) is \(2n\) as in case (i).

In this case the quadratic form \(f\) fixed by \(A\) and \(B\) in the basis of Proposition 2.9 is odd. This follows from the fact that every entry of \(v\) is even and thus the \(n\)th entry of \(B^m v\) is even for every \(0 \leq m \leq n - 1\). Furthermore, \(f_{ij} = 4\) if \(|i - j| = 1\) since the \(n\)th entry of \(Bv\) is 4 so \(e_i^t f e_{i+1} = 4\) for \(1 \leq i \leq n - 1\). Combined with the fact that \(f\) is odd, Lemma 4.1 gives us that all of the basis vectors are in the same connected component of \(X_f\).

(4):
In this case we have that the generators of $H(\alpha, \beta)$ are as in (2.1) with

$$A_i = (-1)^i \text{ for } i = 2, n - 2, n$$

$$A_i = (-1)^i \cdot 2 \text{ for } i = 1, n - 1$$

$$A_i = 0 \text{ otherwise.}$$

and

$$B_i = 0 \text{ for } 2 \leq i \leq n - 2$$

$$B_i = 1 \text{ otherwise}$$

The eigenvector of $C = A^{-1}B$ with eigenvalue 1 is thus $v = (3, -1, 0, \ldots, 0, 1, -1, 2)^t$. Here we have $B$ is of order $2n - 2$.

Note that if $f$ denotes the form fixed by $A$ and $B$ in the basis of Proposition 2.9 we get that $f_{ij}$ is 3 if $|i - j| = 1$, and Lemma 4.1 implies that the basis vectors are in one connected component of $X_f$ since $e_i^t f e_{i+1} = 3$ for all $1 \leq i \leq n - 1$. To see this, note that the $n$th row of $B^m$ is of the form

$$(b_1 \ b_2 \ \cdots \ b_n)$$

where $b_i = 0$ for $i \leq n - m - 1$ and $b_i = i - n + m + 1$ for $i \geq n - m$. Therefore in particular the $n$th entry of $Bv$ is 3 as desired.

(5):

In this case we have that the generators of $H(\alpha, \beta)$ are as in (2.1) with

$$A_i = -1 \text{ for } i = n$$

$$A_i = (-1)^i \cdot 3 \text{ for } i = n - 1, 1$$

$$A_i = (-1)^i \cdot 4 \text{ for } 2 \leq i \leq n - 2$$

and

$$B_i = 0 \text{ for } 2 \leq i \leq n - 2$$

$$B_i = 1 \text{ otherwise}$$

The eigenvector of $C = A^{-1}B$ with eigenvalue 1 is thus $v = (4, -4, 4-4, \ldots, 4, -2, 2)^t$ and $B$ is of order $2n - 2$.

As in case (4), the quadratic form $f$ fixed by $A$ and $B$ is odd. Again, this is because every entry of $v$ is even and thus the $n$th entry of $B^m v$ is even for $0 \leq m \leq n - 1$. Moreover, we have that $f_{ij} = 4$ for $|i - j| = 1$ since the $n$th entry of $Bv$ is 4 so $e_i^t f e_{i+1} = 4$ for $1 \leq i \leq n - 1$. Combined with the fact that $f$ is odd, Lemma 4.1 gives us that all of the basis vectors are in one connected component of $X_f$.

(6):
Here the generators of $H(\alpha, \beta)$ are as in (2.1) with
\[
A_n = 1 \\
A_i = 3 \quad \text{for } i = 1, n - 1 \\
A_i = 4 \quad \text{for } 2 \leq i \leq n - 2
\]
and
\[
B_i = (-1)^i \quad \text{for } i = 1, n - 1, n \\
B_i = 0 \quad \text{for } 2 \leq i \leq n - 2
\]
The eigenvector of $C = A^{-1}B$ with eigenvalue 1 is thus $v = (4, 4, 4, \ldots, 4, 2, 2)^t$ and $B$ is of order $2n - 2$.

Again, the quadratic form $f$ fixed by $A$ and $B$ in the basis of Proposition 2.9 is even since every entry of $v$ is even. Moreover, we have that $f_{ij} = 4$ for $|i - j| = 1$ since the $n$th entry of $Bv$ is 4 so $e_i^tfe_{i+1} = 4$ for $1 \leq i \leq n - 1$. Combined with the fact that $f$ is odd, Lemma 4.1 gives us that all of the basis vectors are in one connected component of $X_f$.

(7):
Here we have that the generators of $H(\alpha, \beta)$ are as in (2.1) with
\[
A_n = 1 \\
A_i = 3 \quad \text{for } i = 1, n - 1 \\
A_i = 4 \quad \text{for } 2 \leq i \leq n - 2
\]
and
\[
B_n = -1 \\
B_i = 0 \quad \text{for } 1 \leq i \leq n - 1
\]
The eigenvector of $C = A^{-1}B$ with eigenvalue 1 is thus $v = (3, 4, 4, \ldots, 4, 3, 2)^t$ and $B$ is of order $n$.

Note that if $f$ denotes the form fixed by $A$ and $B$ in the basis of Proposition 2.9 we get that $f_{ij}$ is 3 if $|i - j| = 1$, and so Lemma 4.1 implies that the basis vectors are in one connected component of $X_f$ since $e_i^tfe_{i+1} = 3$ for all $1 \leq i \leq n - 1$. To see this, we note that the $n$th entry of $Bv$ is 3.

(8):
The basic idea is to use Lemma 4.7 again, however, to show that $v$ and $Bv$ belong to the same connected component is more complicated than in the previous cases (one has to consider paths of longer length). Recall that for every $n \geq 7$ with $\gcd(n + 1, 6) = 2$ there exists a unique monodromy group $H$ in the family $\mathcal{N}_1(3, n, n)$. For $1 \leq i \leq n$ let $v_i := B^{i-1}v$ be the $i$-th basis element of a basis for $L$. If $u \in L$ then $[u]$ denotes the coordinates vector of $u$ with respect to the base $v_1, \ldots, v_n$ and $[u]_i$ is the $i$-coordinate of $[u]$. Corollary 2.11 states that the quadratic form is given by:
\[ f_{i,j} := (v_i, v_j) = \begin{cases} 
-2 & \text{if } |i - j| = 0 \\
-4 & \text{if } |i - j| = 1 \\
-8 & \text{if } |i - j| = 2 \text{ or } |i - j| = n - 1 \\
-11 & \text{if } |i - j| = 3 \text{ or } |i - j| = n - 2 \\
-12 & \text{otherwise} 
\end{cases} \]

\textbf{Lemma 4.9.} Denote \( m := n - 3 \) if \( n \equiv 1 \pmod{6} \) and \( m := n - 5 \) if \( n \equiv 3 \pmod{6} \). Define \( u \in L \) by

\[ [u]_i := \begin{cases} 
1 & \text{if } i \equiv 1 \pmod{6} \text{ and } i \leq m \\
-2 & \text{if } i \equiv 2 \pmod{6} \text{ and } i \leq m \\
2 & \text{if } i \equiv 3 \pmod{6} \text{ and } i \leq m \\
-1 & \text{if } i \equiv 4 \pmod{6} \text{ and } i \leq m \\
0 & \text{otherwise} 
\end{cases} \]

Then, \((u, u) = 2\).

\textit{Proof.} The proof in by induction on \( \left\lfloor \frac{n}{6} \right\rfloor \) (the integral part of \( \frac{n}{6} \)). The induction base is \( n = 7 \) and \( n = 9 \) and it is a direct computation. Assume \( n \geq 10 \) and that the induction hypothesis was proven for integer smaller then \( l := \left\lfloor \frac{n}{6} \right\rfloor \). Define \( a, b \in L \) by

\[ [a]_i := \begin{cases} 
1 & \text{if } i \equiv 1 \pmod{6} \text{ and } i \leq m - 6 \\
-2 & \text{if } i \equiv 2 \pmod{6} \text{ and } i \leq m - 6 \\
2 & \text{if } i \equiv 3 \pmod{6} \text{ and } i \leq m - 6 \\
-1 & \text{if } i \equiv 4 \pmod{6} \text{ and } i \leq m - 6 \\
0 & \text{otherwise} 
\end{cases} \]

and

\[ [b]_i := \begin{cases} 
1 & \text{if } i = m - 3 \\
-2 & \text{if } i = m - 2 \\
2 & \text{if } i = m - 1 \\
-1 & \text{if } i = m \\
0 & \text{otherwise} 
\end{cases} \]

Note that if \( \tilde{f} \) is the form corresponding to the \( n - 6 \) dimensional group in the family \( j = 3 \) then the upper left \( m - 6 \times m - 6 \) of \( \tilde{f} \) is the same as the upper left \( m - 6 \times m - 6 \) of \( F \). Thus, by the induction hypothesis we get that \((a, a) = 2\) and that \((b, b) = (B^{-6(l-1)}b, B^{-6(l-1)}b) = 2\). The equality \( u = a + b \) implies

\[ (u, u) = (a, a) + (b, b) = 4 + \sum_{i=m-3}^{m-6} \sum_{j=1}^{m-6} [u]_i [u]_j f_{i,j} = 2 \]

since \( f_{m-6,m-3} = f_{m-3,m-6} = -11 \) while all the other \( f_{i,j} \) in the above range equal \(-12\). \(\square\)

\textbf{Lemma 4.10.} Assume that \( n \equiv 1 \pmod{6} \) and let \( u \) and \( m \) be as in Lemma 4.9. Denote \( w := u + v_{n-1} \). Then \((w, w) = -2\) while \((w, v_{n-1}) = (w, v_n) = -3\).
Proof. Note that $f_{n-1,1} = -11$, $f_{n-1,m-1} = -11$ and $f_{n-1,m} = -8$ while $f_{n-1,i} = -12$ for $2 \leq i \leq m - 2$. Thus,

$$ (u, v_{n-1}) = \sum_{i=1}^{m} [u_i] f_{n-1,i} = -1, $$

$$ (w, w) = (u, u) + (v_{n-1}, v_{n-1}) + 2(v_{n-1}, u) = 2 - 2 - 2 = -2 $$

and

$$ (w, v_{n-1}) = (v_{n-1}, v_{n-1}) + (v_{n-1}, u) = -1 - 2 = -3. $$

Also, $f_{n,1} = -8$, $f_{n,2} = -11$ and $f_{n,m} = -11$ while $f_{n-1,i} = -12$ for $3 \leq i \leq m - 1$. Thus,

$$ (u, v_n) = \sum_{i=1}^{m} [u_i] f_{n,i} = 1 $$

and

$$ (w, v_n) = (v_n, v_{n-1}) + (v_{n-1}, u) = -4 + 1 = -3. $$

\[ \square \]

**Lemma 4.11.** Assume $n \equiv 5 \pmod{6}$ and let $u$ and $m$ be as in Lemma 4.9. Denote $w := u + v_{n-2}$. Then $(w, w) = -2$ while $(w, v_{n-2}) = (w, v_{n-1}) = -3$.

Proof. Note that $f_{n-2,m} = -11$ and while $f_{n-2,i} = -12$ for $1 \leq i \leq m - 1$. Thus,

$$ (u, v_{n-2}) = \sum_{i=1}^{m} [u_i] f_{n-2,i} = -1, $$

$$ (w, w) = (u, u) + (v_{n-2}, v_{n-2}) + 2(v_{n-2}, u) = 2 - 2 - 2 = -2 $$

and

$$ (w, v_{n-2}) = (v_{n-2}, v_{n-2}) + (v_{n-2}, u) = -1 - 2 = -3. $$

Also, $f_{n-1,1} = -11$ while $f_{n-1,i} = -12$ for $2 \leq i \leq m$. Thus,

$$ (u, v_{n-1}) = \sum_{i=1}^{m} [u_i] f_{n-1,i} = 1 $$

and

$$ (w, v_{n-1}) = (v_{n-1}, v_{n-2}) + (v_{n-2}, u) = -4 + 1 = -3. $$

\[ \square \]

Lemma 4.10 and 4.11 show that $v_{n-2}$ and $v_{n-1}$ are in the same connected component of $X_f$. Thus, also $v = B^{3-n}v_{n-2}$ and $Bv = B^{3-n}v_{n-1}$ are in the same connected component and we can apply Lemma 4.7.

\[ \square \]

By using the same kind of arguments one can show that more families are thin. However since the computations are very tedious, we will only state the result we were able to prove.
Theorem 4.12. The family $N_1(j,n,n)$ where $n \equiv l \pmod{2j}$ is thin if one of the following conditions holds:

1. $l = j$ or $l = j - 2$.
2. $l \leq \frac{j+1}{2}$ and $l + 1$ divides $j - 1$.
3. $l \geq \frac{2j-5}{2}$ and $2j - l - 1$ divides $j - 1$.

It is possible that one might be able to remove the congruence conditions above. For example, the first case which is not covered by the theorem above is $N_1(7,17,17)$, in which there is a path of length 4 in $X_f$ that connects $v$ and $Bv$ (and hence the group is thin).

5. Numerical results and data

5.1. Hyperbolic groups $H(\alpha, \beta)$, dimension $n \leq 9$. In this section, we list all of the primitive hyperbolic hypergeometric monodromy groups, including the sporadic ones which do not fall into any of the families found in Section 2.3. We note that the sporadic groups are all in dimension $n \leq 9$ and are easily determined using the method from Section 2.2, given the sporadic finite hypergeometric monodromy groups listed in [B-H] (or by listing for each $n$ all the hyperbolic hypergeometric $(\alpha, \beta)$’s and recording which lie in one of our seven families). Our list is split into two tables: Table 2, which lists all even monodromy groups in dimension $n \leq 9$ as well as which family (if any) they fit into, and Table 3, which lists all odd monodromy groups in dimension $n \leq 9$ along with the associated family. In Table 2 we also list the invariant factors of the associated quadratic lattice and specify in which cases we are able to prove that the monodromy group is thin (thinness here is always confirmed using the minimal distance graph method described above). In Table 3 we specify when the subgroup $H_r$ of $H(\alpha, \beta)$ is contained in $R_f$ – note that Nikulin’s results from [N1] do not apply to the odd case and hence we cannot immediately deduce thinness in these lower dimensional odd cases (although with extra work this can probably be done). The groups $H(\alpha, \beta)$ where $[H(\alpha, \beta) : H_r] = \infty$ (thus, those for which the minimal distance graph method does not prove thinness) are marked with a * in the last column.

Table 3: Odd monodromy groups: dimensions 5, 7, 9.

5.2. Some numerics for hyperbolic hypergeometric monodromy groups. While our certificate for being thin succeeds in many cases as demonstrated in Sections 4 and 5, there are families such as $\mathcal{N}_4(j, k, n)$ for which we found almost no paths between the basis vectors in the minimal distance graph. If indeed the corresponding components of $X_f$ are singletons for members of this family, then clearly a variation of the minimal distance graph is needed if this approach is to work. A crude, and it appears mostly reliable, test for the size of $H = H(\alpha, \beta)$ in $O(L)$ is to simply count the number of elements in $H$ in a large ball. That is, let $T$ be a large number and let

$$N_H(T) := \{ \gamma \in H \mid \text{trace}(\gamma^t \gamma) \leq T^2 \}.$$
If $H$ is arithmetic then it is known ([L-P]) that

$$N_H(T) \sim \frac{c_n T^{n-2}}{\text{Vol}(H \backslash O_f(\mathbb{R}))}, \text{ as } T \to \infty. \quad (5.2)$$

Thus to probe the size of $H$ we generate elements in $H$ using our defining generators and try to determine $N_H(T)$ for $T$ quite large.

The difficulty is that we don’t know which elements of $O(L)$ are in $H$ and the above procedure (by going to large generations of elements in $H$ gotten from the generating set) only gives a lower bound for $N_H(T)$. In any case we can compute in this way a lower bound for $\log(N_H(T))/\log T$ for $T$ large. If this is essentially $n - 2$ then this suggests that $H$ is arithmetic, while if this number is less than $n - 2$ it suggests that $H$ is thin (if $H$ is geometrically finite then this quantity should be an approximation to the Hausdorff dimension of the limit set of $H$ (see for example [L-P]). We have run this crude test for many of our hyperbolic hypergeometric monodromies and it gives the correct answer in the cases where we have a rigorous treatment. For example, in Figures 2 and 3 we give a plot of $\log(N_H(T))$ versus $\log T$ for the arithmetic examples $\alpha = (\frac{1}{3}, \frac{1}{2}, \frac{2}{3}), \beta = (0, \frac{1}{4}, \frac{3}{4})$ and $\alpha = (\frac{1}{3}, \frac{1}{2}, \frac{2}{3}), \beta = (0, \frac{1}{4}, \frac{3}{4})$. The similar plots for four examples with $n = 5$, and for which our certificate failed are given in Figures 4, 5, 6, and 7 below. Based on these, it appears that these $H$‘s are all thin. Further such experimentation is consistent with Conjecture 2 in the Introduction and even that for $n \geq 5$, every hyperbolic hypergeometric monodromy group is thin.
Figure 3. \( \log(N_H(T)) \) versus \( \log T \) graph for \( H(\alpha, \beta) \) where \( \alpha = \left(\frac{1}{3}, \frac{1}{2}, \frac{2}{3}\right) \), \( \beta = \left(0, \frac{1}{6}, \frac{5}{6}\right) \).

Figure 4. \( \log(N_H(T)) \) versus \( \log T \) graph for \( H(\alpha, \beta) \) where \( \alpha = \left(\frac{1}{5}, \frac{1}{2}, \frac{3}{5}, \frac{4}{5}\right) \), \( \beta = \left(0, 0, \frac{1}{3}, \frac{2}{3}\right) \).

Figure 5. \( \log(N_H(T)) \) versus \( \log T \) graph for \( H(\alpha, \beta) \) where \( \alpha = \left(\frac{1}{8}, \frac{3}{8}, \frac{3}{8}, \frac{7}{8}\right) \), \( \beta = \left(0, 0, \frac{1}{6}, \frac{5}{6}\right) \).
Figure 6. \( \log(N_H(T)) \) versus \( \log T \) graph for \( H(\alpha, \beta) \) where \( \alpha = \left( \frac{1}{6} , \frac{1}{3} , \frac{1}{2} , \frac{2}{3} , \frac{5}{6} \right) \), \( \beta = (0, 0, 0, \frac{1}{3}, \frac{3}{4}) \).

Figure 7. \( \log(N_H(T)) \) versus \( \log T \) graph for \( H(\alpha, \beta) \) where \( \alpha = \left( \frac{1}{6} , \frac{1}{2} , \frac{1}{2} , \frac{1}{2} , \frac{5}{6} \right) \), \( \beta = (0, 0, 0, \frac{1}{3}, \frac{2}{3}) \).

Appendix

In this appendix, we consider the six 3-dimensional hyperbolic hypergeometric monodromy groups and show that they are all arithmetic. Our method is to determine the preimage of the groups in the spin double cover \( \text{SL}_2(\mathbb{R}) \) of \( \text{SO}(2, 1) \) and work in the setting of \( \text{SL}_2 \). Once we pull back to \( \text{SL}_2 \), we rely on one of the following strategies. If the quadratic form \( f \) that is fixed by hyperbolic hypergeometric monodromy group \( H \) is isotropic over \( \mathbb{Q} \) then one can find \( M \in \text{GL}_3(\mathbb{Q}) \) such that \( M^t f M \) is some scalar multiple of \( \mathbb{Q}^2 \) below. Moreover, under such a change of variable, the preimage of \( H \cap \text{SO}_f \) in the spin double cover of \( \text{SO}_f \) can be made to sit inside \( \text{SL}_2(\mathbb{Z}) \), and in this setting showing that the group is finite index is usually straightforward. Out of the six 3-dimensional hyperbolic hypergeometric monodromy groups, four fix an isotropic form \( f \), and in those cases we
show that the preimage of the group in the spin double cover of $SO_f$ contains a principle congruence subgroup of $SL_2(\mathbb{Z})$.

If the form $f$ fixed by $H$ is anisotropic, we again pull back to the spin double cover $\Gamma$ of $SO_f$ in $SL_2(\mathbb{R})$ and, after generating several elements of $\Gamma$, construct a region in the upper half plane which contains a fundamental domain for $\Gamma$ acting on $\mathbb{H}$ (this method works for the isotropic case as well). Specifically, a Dirichlet fundamental domain for $\Gamma$ is given by

$$F_{p_0} = \bigcap_{\gamma \in \Gamma} \{ z \in \mathbb{H} \mid d(z, p_0) \leq d(z, \gamma p_0) \} = \bigcap_{\gamma \in \Gamma} H(\gamma, p_0)$$

where $p_0$ is any base point and $H(\gamma, p_0)$ is a closed half space. One can prove that $F_{p_0}$ is compact (and hence $\Gamma$ is arithmetic) if the intersection $\cap_{\gamma} H(\gamma, p_0)$ is compact even when taken over a finite number of elements $\gamma \in \Gamma$. Note that this method uses the same idea as described in Section 5.2: generating elements of $\Gamma$ to say something about thinness, but in this case it can actually prove whether the group is thin or not.

Throughout this section, we let $Q_1 = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -1 \end{bmatrix}$ and $Q_2 = \begin{bmatrix} 0 & 0 & -\frac{1}{2} \\ 0 & 1 & 0 \\ -\frac{1}{2} & 0 & 0 \end{bmatrix}$.

For these two forms we have the following spin homomorphisms from $SL_2(\mathbb{R})$ into the $SO_{Q_1}$ and $SO_{Q_2}$, respectively (see [C]).

$$\begin{align*}
(a & \ b) \\
(c & \ d)
\end{align*} \mapsto \rho_1 \begin{pmatrix} \frac{1}{2}(a^2 + b^2 - c^2 + d^2) & ac - bd & \frac{1}{2}(a^2 - b^2 + c^2 - d^2) \\
ac - bd & bc + ad & ab + cd \\
\frac{1}{2}(a^2 + b^2 - c^2 - d^2) & ac + bd & \frac{1}{2}(a^2 + b^2 + c^2 + d^2) \end{pmatrix}
$$

$$\begin{align*}
(a & \ b) \\
(c & \ d)
\end{align*} \mapsto \rho_2 \begin{pmatrix} a^2 & 2ac & c^2 \\
ab & ad + bc & cd \\
b^2 & 2bd & d^2 \end{pmatrix}
$$

Example 1: $\alpha = (\frac{1}{2}, \frac{1}{2}, \frac{1}{2}), \beta = (0, 0, 0)$.

In this case $H(\alpha, \beta) \subset O_f(\mathbb{Z})$ with generators $A, B$ where

$$f = \begin{bmatrix} 1 & 0 & -3 \\ 0 & 1 & 0 \\ -3 & 0 & 1 \end{bmatrix}, A = \begin{bmatrix} 0 & 0 & -1 \\ 1 & 0 & -3 \\ 0 & 1 & -3 \end{bmatrix}, B = \begin{bmatrix} 0 & 0 & 1 \\ 1 & 0 & -3 \\ 0 & 1 & 3 \end{bmatrix}.$$

Note that $2(M^t f M) = Q_2$ where

$$M = \begin{bmatrix} -1/8 & 1/4 & -1/4 \\ -1/4 & 0 & 1/2 \\ -1/8 & -1/4 & -1/4 \end{bmatrix}$$

\footnote{In doing this, we use Sage to determine generators for $\Gamma(N)$ for various $N$.}
and conjugation by $M$ gives an isomorphism of the subgroup $\langle A^2, B \rangle \subset H(\alpha, \beta) \cap SO_f(\mathbb{Z})$ with the subgroup $\langle A', B' \rangle \subset SO_{Q_2}(\mathbb{Z})$ where

$$A' = \begin{bmatrix} 1 & 8 & 16 \\ 0 & 1 & 4 \\ 0 & 0 & 1 \end{bmatrix}, B' = \begin{bmatrix} 1 & 0 & 0 \\ 1 & 1 & 0 \\ 1 & 2 & 1 \end{bmatrix}.$$ 

The preimage of this group in $SL_2(\mathbb{Z})$ under the spin homomorphism in (5.4) is the group $\langle \pm X, \pm Y \rangle$ where

$$X = \begin{bmatrix} 1 & 0 \\ 4 & 1 \end{bmatrix}, Y = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}.$$ 

This group contains the generators

$$\begin{bmatrix} 1 & 3 \\ 0 & 1 \end{bmatrix}, \begin{bmatrix} -15 & 4 \\ -4 & 1 \end{bmatrix}, \begin{bmatrix} 5 & -4 \\ 4 & -3 \end{bmatrix}, \begin{bmatrix} 9 & -16 \\ 4 & -7 \end{bmatrix}, \begin{bmatrix} 13 & -36 \\ 4 & -11 \end{bmatrix}$$

of $\Gamma(4)$. Hence $H(\alpha, \beta)$ is itself arithmetic. In addition, our second strategy of finding a region which contains a fundamental domain for $H$ yields the compact region shown in Figure 8.

**Example 2:** $\alpha = (\frac{1}{3}, \frac{1}{2}, \frac{2}{3}), \beta = (0, 0, 0)$.

In this case $H(\alpha, \beta) \subset O_f(\mathbb{Z})$ with generators $A, B$ where

$$f = \begin{bmatrix} 7 & 1 & -17 \\ 1 & 7 & 1 \\ -17 & 1 & 7 \end{bmatrix}, A = \begin{bmatrix} 0 & 0 & -1 \\ 1 & 0 & -2 \\ 0 & 1 & -2 \end{bmatrix}, B = \begin{bmatrix} 0 & 0 & 1 \\ 1 & 0 & -3 \\ 0 & 1 & 3 \end{bmatrix}.$$ 

Note that $(M^t f M) = 3 \cdot Q_2$ where

$$M = \begin{bmatrix} -1/4 & 0 & 1/12 \\ -1/2 & 1/2 & 1/12 \\ 1/4 & -1/2 & 1/3 \end{bmatrix}$$

and conjugation by $M$ gives an isomorphism of the subgroup $\langle A^2, B \rangle \subset H(\alpha, \beta) \cap SO_f(\mathbb{Z})$ with the subgroup $\langle A', B' \rangle \subset SO_{Q_2}(\mathbb{Z})$ where

$$A' = \begin{bmatrix} 1 & -2 & 1 \\ 3 & -5 & 2 \\ 9 & -12 & 4 \end{bmatrix}, B' = \begin{bmatrix} 1 & -2 & 1 \\ 0 & 1 & -1 \\ 0 & 0 & 1 \end{bmatrix}.$$ 

The preimage of this group in $SL_2(\mathbb{Z})$ under the spin homomorphism in (5.4) is the group $\langle \pm X, \pm Y \rangle$ where

$$X = \begin{bmatrix} -1 & -3 \\ 1 & 2 \end{bmatrix}, Y = \begin{bmatrix} 1 & 0 \\ -1 & 1 \end{bmatrix}.$$ 

This group contains the generators

$$\begin{bmatrix} 1 & 3 \\ 0 & 1 \end{bmatrix}, \begin{bmatrix} -8 & 3 \\ -3 & 1 \end{bmatrix}, \begin{bmatrix} 4 & -3 \\ 3 & -2 \end{bmatrix}.$$
of $\Gamma(3)$. Hence $H(\alpha, \beta)$ is itself arithmetic. In addition, our second strategy of finding a region which contains a fundamental domain for $H$ yields the compact region shown in Figure 9.

Example 3: $\alpha = (\tfrac{1}{4}, \tfrac{1}{2}, \tfrac{3}{4}), \beta = (0, 0, 0)$.

In this case $H(\alpha, \beta) \subset O_f(\mathbb{Z})$ with generators $A, B$ where

\[
\begin{bmatrix}
  3 & 1 & -5 \\
  1 & 3 & 1 \\
-5 & 1 & 3
\end{bmatrix},
\begin{bmatrix}
  0 & 0 & -1 \\
  1 & 0 & -1 \\
  0 & 1 & -1
\end{bmatrix},
\begin{bmatrix}
  0 & 0 & 1 \\
  1 & 0 & -3 \\
  0 & 1 & 3
\end{bmatrix}.
\]

Note that $M^t f M = Q_1$ where

\[
M = \begin{bmatrix}
  1/4 & 1/4 & 1/2 \\
  0 & 1/2 & 0 \\
-1/4 & 1/4 & 1/2
\end{bmatrix}
\]

and conjugation by $M$ gives an isomorphism of the subgroup $\langle A^2, B \rangle \subset H(\alpha, \beta) \cap SO_f(\mathbb{Z})$ with the subgroup $\langle A', B' \rangle \subset SO_{Q_1}(\mathbb{Z})$ where

\[
A' = \begin{bmatrix}
  -1 & 0 & 0 \\
  0 & -1 & 0 \\
  0 & 0 & 1
\end{bmatrix},
B' = \begin{bmatrix}
  1 & -2 & -2 \\
  2 & -1 & -2 \\
-2 & 2 & 3
\end{bmatrix}.
\]

The preimage of this group in $SL_2(\mathbb{Z})$ under the spin homomorphism in (5.3) is the group $\langle \pm X, \pm Y \rangle$ where

\[
X = \begin{bmatrix}
  0 & 1 \\
-1 & 0
\end{bmatrix},
Y = \begin{bmatrix}
  0 & 1 \\
-1 & 2
\end{bmatrix}
\]

and $\pm XY, \pm YX$ generate the principal congruence subgroup $\Gamma(2)$. Hence $H(\alpha, \beta)$ is itself arithmetic. In addition, our second strategy of finding a region which contains a fundamental domain for $H$ yields the compact region shown in Figure 10.

Example 4: $\alpha = (\tfrac{1}{6}, \tfrac{1}{2}, \tfrac{5}{6}), \beta = (0, 0, 0)$.

In this case $H(\alpha, \beta) \subset O_f(\mathbb{Z})$ with generators $A, B$ where

\[
\begin{bmatrix}
  5 & 3 & -3 \\
  3 & 5 & 3 \\
-3 & 3 & 5
\end{bmatrix},
\begin{bmatrix}
  0 & 0 & -1 \\
  1 & 0 & 0 \\
  0 & 1 & 0
\end{bmatrix},
\begin{bmatrix}
  0 & 0 & 1 \\
  1 & 0 & -3 \\
  0 & 1 & 3
\end{bmatrix}.
\]

Note that $M^t f M = Q_1$ where

\[
M = \begin{bmatrix}
  1/4 & -1/2 & 3/4 \\
  1/4 & 1/2 & -3/4 \\
  0 & 0 & 1/2
\end{bmatrix}
\]
and conjugation by $M$ gives an isomorphism of the subgroup $\langle A^2, B \rangle \subset H(\alpha, \beta) \cap SO_f(\mathbb{Z})$ with the subgroup $\langle A', B' \rangle \subset SO_{Q_1}(\mathbb{Z}[\frac{1}{2}])$ where

$$A' = \begin{bmatrix} -1/2 & -1 & 1/2 \\ 1 & -1 & 1 \\ 1/2 & -1 & 3/2 \end{bmatrix}, \quad B' = \begin{bmatrix} 1/2 & -1 & -1/2 \\ 1 & 1 & 1 \\ 1/2 & 1 & 3/2 \end{bmatrix}.$$

The preimage of this group in $SL_2(\mathbb{Z})$ under the spin homomorphism in (5.3) is the group $\langle \pm X, \pm Y \rangle$ where

$$X = \begin{bmatrix} 1 & 1 \\ -1 & 0 \end{bmatrix}, \quad Y = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}.$$

and $YX^4, Y$ are a well-known generating set for all of $SL_2(\mathbb{Z})$. Hence $H(\alpha, \beta)$ is itself arithmetic. In addition, our second strategy of finding a region which contains a fundamental domain for $H$ yields the compact region shown in Figure 11.

**Example 5:** $\alpha = (\frac{1}{1}, \frac{1}{2}, \frac{2}{3}), \beta = (0, \frac{1}{1}, \frac{3}{4})$.

In this case $H(\alpha, \beta) \subset O_f(\mathbb{Z})$ with generators $A, B$ where

$$f = \begin{bmatrix} 5 & -1 & -7 \\ -1 & 5 & -1 \\ -7 & -1 & 5 \end{bmatrix}, \quad A = \begin{bmatrix} 0 & 0 & -1 \\ 1 & 0 & -2 \\ 0 & 1 & -2 \end{bmatrix}, \quad B = \begin{bmatrix} 0 & 0 & 1 \\ 1 & 0 & -1 \\ 0 & 1 & 1 \end{bmatrix}.$$

In this case $f$ is anisotropic over $\mathbb{Q}$, and hence we turn to our strategy of approximating the fundamental domain to prove that $H$ is arithmetic: we produce the compact region shown in Figure 12 which contains the fundamental domain of $H$.

**Example 6:** $\alpha = (\frac{1}{3}, \frac{1}{7}, \frac{2}{3}), \beta = (0, \frac{1}{6}, \frac{5}{6})$.

In this case $H(\alpha, \beta) \subset O_f(\mathbb{Z})$ with generators $A, B$ where

$$f = \begin{bmatrix} 1 & 0 & -2 \\ 0 & 1 & 0 \\ -2 & 0 & 1 \end{bmatrix}, \quad A = \begin{bmatrix} 0 & 0 & -1 \\ 1 & 0 & -2 \\ 0 & 1 & -2 \end{bmatrix}, \quad B = \begin{bmatrix} 0 & 0 & 1 \\ 1 & 0 & -2 \\ 0 & 1 & 2 \end{bmatrix}.$$

In this case $f$ is anisotropic over $\mathbb{Q}$, and hence we turn to our strategy of approximating the fundamental domain to prove that $H$ is arithmetic: we produce the compact region shown in Figure 13 which contains the fundamental domain of $H$.
