Synthesis, Characterization, and DFT-Based Electronic and Nonlinear Optical Properties of Methyl 1-(arylsulfonyl)-2-aryl-1H-benzo[d]imidazole-6-carboxylates

Shumaila Aslam, Muhammad Haroon, Tashfeen Akhtar,* Muhammad Arshad, Muhammad Khalid,* Zahid Shafiq, Muhammad Imran, and Aman Ullah*

ABSTRACT: Herein, a series of N-1-sulfonyl substituted derivatives of 2-substituted benzimidazoles (2a–2e) were designed and synthesized via structural tailoring of the acceptor part of donor–π–acceptor schemes, and their nonlinear optic (NLO) characteristics were reported. The structures of 2a–2e were investigated and their characterization was accomplished by employing spectroscopic procedures, i.e., UV–vis, FT-IR, and ¹H and ¹³C NMR. Further, a density functional theory (DFT) approach was used to calculate UV–vis, vibrational, and ¹H and ¹³C NMR techniques; frontier molecular orbitals (FMOs); global reactivity parameters (GRPs); natural bond orbitals (NBOs); optical and vibrational analysis; and nonlinear optics (NLO). The most promising results were obtained for 6-nitro-2-(4-nitrophenyl)-1-(4-nitrophenylsulfonyl)-1H-benzo[d]imidazole among entitled compounds, as it exhibited the highest ⟨α⟩ and βtot values, showing it is an eye-catching NLO material. This DFT study evokes the interest of researchers regarding the development of benzimidazole-based tempting NLO compounds that could be beneficial in modern hi-tech applications.

INTRODUCTION

Benzimidazoles are heterocyclic compounds also known as 1,3-benzodiazoles.¹ This bicyclic system consists of the fusion of imidazole and benzene. Benzimidazole is also a part of naturally occurring vitamin B₁₂ as N-ribosyl-dimethylbenzimidazole.² In benzimidazoles, the –NH– group shows relatively strong acidic character and acts as a site for electrophilic substitution. The benzimidazole scaffold is also beneficial for the growth of molecules, which possess many pharmaceutical or biological applications. Various commercially available drugs contain benzimidazole as part of their structure,³ as shown in Figure 1.

A variety of biological applications accompany benzimidazole and its derivatives. Derivatives containing thio, acetamido, long chains of propyl, and thiazole-amino functionalities at the –NH group result in good antiulcer activity.⁴ Antihelmintic,⁶ antiviral, anti-HIV,⁷ antifungal,⁸ anticancer, cardio tonic,⁹ antihypertensive, and antihistaminic¹⁰–¹² activities are also associated with benzimidazoles. In chemistry, the reactivity is of key importance because it is in confidential association with the reaction mechanism, hence allowing subsequent understanding of chemical reactions as well as improving the procedure of synthesis to develop novel materials. DFT calculation is proved to be one of the prominently utilized probes for investigating the molecular properties.¹³

Herein, taking the imidazole-based structure as a reference point, various derivatives with a basic structural core of 2-phenyl-2,3-dihydro-1H-benzo[d]imidazole are designed and synthesized by modulation of the various substituent groups. A detailed literature survey has revealed that the synthesized molecules have neither been reported nor efficiently investigated in terms of NLO response so far. Therefore, an exclusive computational investigation has been done to explore their NLO

Figure 1. Commercially available drugs containing benzimidazole.
response parameters through various DFT-based analyses. So, the present DFT calculations provide a detailed account of the electronic structure, electronic transitions, molecular surfaces, global reactivity descriptors, natural population, and NLO response features of the 2-phenyl-2,3-dihydro-1H-benzo[d]imidazole-based derivatives at the M06/6-311G(d,p) and CAM-B3LYP/6-311G(d,p) levels of theory. The optimistic opinion is that the presented DFT study will prove to be a foundation not only for the researchers but also for technicians to manufacture materials possessing extraordinary NLO behavior.

■ RESULTS AND DISCUSSION

Benzimidazole-based derivatives (2a–2e) having arylsulfonylmoiety at the N − 1 position were prepared in three steps as shown in Scheme 1. First of all, methyl 3,4-diaminobenzoate was synthesized from simple esterification of 3,4-diaminobenzoic acid. In the second step, 2-substituted benzimidazoles (1), which act as an intermediate for the formation of compounds 2a–2e, were synthesized via two synthetic routes. In first synthetic route, methyl 3,4-diaminobenzoate was treated with benzaldehyde in the presence of nickel acetate [Ni(OAc)₂] using chloroform (CHCl₃) as a solvent. In the second synthetic route, 6-nitro-3,4-diaminobenzene was refluxed (48 h) with benzaldehyde in the presence of sodium meta-bisulphite (Na₂S₂O₅) using dimethylformamide (DMF) solvent to get respective intermediate 1. In the third step, targeted N-sulfonyl derivatives of I were obtained by simple stirring (24 h) of intermediate 1 with respective arylsulfonyl chloride in the presence of sodium hydride (NaH) using tetrahydrofuran (THF) as a solvent. The compounds (2a–2e), which appeared as a single spot on the thin layer chromatographic (TLC) plate, separated from aqueous media via a solvent extraction technique. The characterization of compounds (2a–2e) was performed by well-recognized spectroscopic techniques like, FT-IR, UV, and ¹H and ¹³C NMR.

The total numbers of proton and carbon signals are verified by ¹H and ¹³C NMR data. In ¹H NMR, a simulated three-proton singlet is observed within the range of 3.32−3.39 ppm at CAM-B3LYP and 3.12−3.21 ppm at the M06 level of theory, which is in good correlation with experimental values (3.67−3.84 ppm) assigned to methyl (−CH₃) of the ester functionality. All other proton signals are seen within the aromatic region with respect to their specific integration and coupling constant values (see Tables S1−S5 and Figures S3, S7, S11, S15, and S19). In ¹³C NMR, carbonyl carbon (C=O) is identified within the range of 165.5−167.1 ppm, which exhibited good harmony with simulated values at 163.99−164.39 ppm at CAM-B3LYP and 170.14−171.48 ppm at the M06 functional. The rest of the carbon signals are observed within the aromatic region according to the substitution pattern (see Tables S1−S5 and Figures S4, S8, S12, S16, and S20). Both ¹H and ¹³C NMR confirmed the number of proton and carbon signals for compounds 2a–2e (see Scheme 2).

■ FRONTIER MOLECULAR ORBITAL (FMO) INVESTIGATION

The FMOs investigations are regarded as significant factors in elucidating diverse perceptions like optical properties, chromophore interactions, charge transfer, chemical stability, and reactivity.¹⁴⁻¹⁵ The electron-rich highest occupied molecular orbital (HOMO) possesses charge donating aptitude, while the electron-deficient lowest unoccupied molecular orbital (LUMO) manifested electron accepting capability. Comounds with s higher E̵gap are considered as rigid and slightly reactive and hold excellent kinetic stability. Due to this reason, the softer compounds owning smaller E̵gap and enhanced polarizability are believed to be magnificent candidates for

Scheme 2. Structural Modulation Representation of 2a−2e
qualitative estimation of the NLO response. The energies, i.e., $E_{\text{HOMO}}$, $E_{\text{LUMO}}$, and $\Delta E$ of 2a–2e were determined with the CAM-B3LYP/6-311G(d,p) and M06/6-311G(d,p) functionals, and their results are listed in Table 1.

Table 1. Computed $E_{\text{LUMO}}$, $E_{\text{HOMO}}$, and $\Delta E$ of 2a–2e

| compounds | $E_{\text{HOMO}}^a$ | $E_{\text{LUMO}}^a$ | energy gaps$^a$ | $E_{\text{HOMO}}^b$ | $E_{\text{LUMO}}^b$ | energy gaps$^b$ |
|-----------|---------------------|---------------------|-----------------|---------------------|---------------------|-----------------|
| 2a        | −7.977              | −0.866              | 7.111           | −6.952              | −1.960              | 4.992           |
| 2b        | −7.815              | −0.623              | 7.192           | −6.798              | −1.684              | 5.114           |
| 2c        | −7.847              | −1.076              | 6.771           | −6.831              | −2.151              | 4.680           |
| 2d        | −8.129              | −2.063              | 6.066           | −8.129              | −2.063              | 6.066           |
| 2e        | −6.302              | −2.421              | 3.881           | −5.385              | −3.543              | 1.842           |

$^a$CAM-B3LYP/6-311G(d,p) level of theory, energy in eV. $^b$M06/6-311G(d,p) level of theory, energy in eV.

Figure 2. FMO diagrams of 2a–2e with the CAM-B3LYP/6-311G(d,p) functional.
found to be the highest among all of the investigated compounds. This might be due to the existence of a hydroxyl (−OH) moiety, which has the lowest value of the −I effect as compared to −Cl, −NH₂, and −NO₂ groups, because of which the attraction of the electronic cloud toward the acceptor is lower. The ascending order of Fₜᵢ for entitled compounds at CAM-B3LYP and M06 levels of density functional theory is found to be 2e > 2d > 2c > 2a > 2b, and 2e > 2c > 2a > 2b < 2d, respectively. Figure 2 displays the diagrammatic representation of FMOs of 2a−2e compounds at CAM-B3LYP/6-311G(d,p), while FMO diagrams at the M06/6-311G(d,p) level are presented in Figure S21. From Figure 2, it can be noted that the electronic cloud is located all over the molecules in both HOMO and LUMO orbitals for 2a and 2b molecules, while for 2c−2e, the charge density is concentrated over the whole molecule in HOMO and at Aᵢ in the case of LUMO (see Figures 2 and S21). With the M06 functional, the electronic cloud for LUMO/HOMO is located at the central donor and π-bridge to major and minor extents on acceptors in 2a and 2e. Moreover, in 2b−2d, for both the LUMO and HOMO, electronic charge density is concentrated all over the molecule, except A₁. An effective charge transfer from the HOMO to LUMO along with lower energy is seen for all compounds, which indicated that these compounds might prove to be the best nonlinear candidates for various NLO applications.

### GLOBAL REACTIVITY PARAMETERS (GRPs)

The energies of LUMO, HOMO, and ΔE obtained from FMO analysis are effectively practiced to estimate global reactivity parameters (GRPs). This leads to an interpretation of internal charge transfer, stability, and chemical reactivity of 2a−2e.²²−²⁴ The compounds exhibiting a larger energy gap are considered as harder, thermodynamically stable, and less reactive.²⁵ In contrast to this, compounds having smaller energy gap are regarded to be soft exhibiting a flexible nature, lesser kinetic stability, and higher reactivity.²⁶−²⁸ The ionization potential alludes to the electron donating capability of a compound, while electronegativity expresses its capability to accept electrons. Chromophores with a greater value of hardness and chemical potential are regarded as stable molecules.²⁹ Global reactivity parameters (GRPs) for entitled chromophores are calculated by utilizing eqs S1−S7, and the results are shown in Table S36.

In this study, it is investigated that at the CAM-B3LYP level, compound 2e has the smallest energy gap, hence it is softer and more reactive with a softness value of 0.258 eV among all the derivatives. The diminishing order of softness values is 2e > 2d > 2c > 2a > 2b. A larger ΔE is demonstrated by compound 2b, so it is less reactive with a softness value of 0.139 eV and is more stable with a greater value of hardness of 3.596 eV. The declining order of hardness values is 2b > 2a > 2c > 2d > 2e. The greatest ionization potential value of 8.129 eV is exhibited by 2d with an overall decreasing order of 2d > 2a > 2c > 2b > 2e. The greater electrophilicity index value of 4.901 eV is shown by 2e with the overall order of electrophilicity index as 2e > 2d > 2c > 2a > 2b. By utilizing the M06 functional, compound 2e exhibits the smallest energy gap, so it is more reactive and softer. The descending order of softness is 2e > 2c > 2a > 2b > 2d. The larger energy gap is exhibited by compound 2b; hence, it is less reactive and soft with a softness value of 0.196 eV and has a greater hardness value of 2.557 eV with more stability. The decreasing order of hardness values is as follows: 2d > 2b > 2a > 2c > 2e. Compound 2d exhibits a much greater value of ionization potential as 8.129 eV with a decreasing order of 2d > 2c > 2b > 2a. A larger value of the electrophilicity index (10.818eV) is demonstrated by compound 2e with a smaller value of hardness and greater value of softness. The overall order of electrophilicity index decreases as follows: 2e > 2c > 2b > 2a. A comparative study discloses that softness values of all the compounds are greater than hardness, therefore all of these compounds are highly reactive with less kinetic stability. Hence, all of these compounds might be proven as better NLO candidates with advanced applications in modern research. From the aforementioned discussion, it is thoroughly observed that with both functionals, i.e., CAM-B3LYP and M06, the designed compound 2e exhibits better results. In summary, the results obtained at the M06 level are observed to be potentially better in comparison with those for CAM-B3LYP. Therefore, M06 is the best suited level for investigating the NLO response of the afore-mentioned molecules.

### NATURAL BOND ORBITAL (NBO) ANALYSIS

The NBO investigation is revealed as an adept technique to examine the interactions between various bonds and to examine the charge transfer process among filled and vacant orbitals.³⁰−³³ The stabilization energies are calculated on account of this charge transfer process, and their higher values indicate reliable donor−acceptor interactions.³²,³³ In this scenario, a better understanding of occupied and unoccupied orbitals is gained.³⁴ The two levels of theory were utilized, i.e., CAM-B3LYP and M06 for performing an NBO analysis on the optimized structures of compounds 2a−2e. The results studied for CAM-B3LYP and M06 functionals are tabulated in Tables S6−S10 and S11−S15, respectively. The second-order perturbation method is used to obtain stabilization energies in NBO analysis through eq 1.

\[
E^{(2)} = q_i \left( \epsilon_j - \epsilon_i \right)
\]

where \(i\) and \(j\) represent the donor and acceptor, accordingly; \(q_i\), \(\epsilon_i\), and \(\epsilon_j\) represent the orbital occupancy and the diagonal and off-diagonal NBO Fock matrixes, while \(E^{(2)}\) refers to the stabilization energy elements.

The CT from donor (occupied orbitals) to acceptor (unoccupied orbitals) is calculated among four kinds of electronic transitions in all of the studied compounds. These transitions include \(\pi \rightarrow \pi^*\), \(\sigma \rightarrow \sigma^*\), \(\pi \pi^*\), and \(\sigma \pi^*\), among which the most important type is \(\pi \rightarrow \pi^*\) due to the conjugation of \(\pi\) electrons. The \(\sigma \rightarrow \sigma^*\) transitions are less dominant, and \(\pi \pi^*\) and \(\sigma \pi^*\) are dominant electronic excitations. The CT in chromophores can be investigated by investigating the major \(\pi \rightarrow \pi^*\) transitions.

The study performed with CAM-B3LYP shed in compound 2a that \(\pi(C32−C38) \rightarrow \pi^*(C27−C29)\) displayed a maximum stabilization energy of 34.76 kcal/mol while \(\pi(C22−O23) \rightarrow \pi^*(C17−C21)\) presented the smallest energy of 4.63 kcal/mol. Among \(\sigma \rightarrow \sigma^*\) transitions, the superior energy of stabilization of 8.03 kcal/mol is observed in the \(\sigma(C17−C21) \rightarrow \sigma^*(C11−N13)\) transition. Likewise, \(\sigma(C22−O39) \rightarrow \sigma^*(C40−H42)\) presents the lowest energy value of 0.50 kcal/mol. The transition LP(2O39) \(\rightarrow \pi^*\) (C22−C23) showed a $8.88$ kcal/mol energy value which displayed the greater stability. The energy value of 38.51 kcal/mol is observed as the lowest energy value due to the LP(2O32) \(\rightarrow \sigma^*\) (C22−O39) transition.

In compound 2b, the \(\pi(C32−C34) \rightarrow \pi^*(C27−C29)\) transition with a 42.83 kcal/mol energy value has a greater
value of stabilization. In addition, the transition from \( \sigma^*(C22-O23) \rightarrow \sigma^*(C17-C21) \), with 4.60 kcal/mol, expressed a lower value. The largest \( \sigma \rightarrow \sigma^* \) transition energy value of 7.96 kcal/mol is shown by \( \sigma(C17-C21) \rightarrow \sigma^*(C11-N13) \) in 2b, and the lowest value is 0.51 kcal/mol in \( \sigma(C22-O44) \rightarrow \sigma^*(C45-H47) \). Among electronic transitions, the largest feasible transition is \( LP2(O44) \rightarrow \sigma^*(C22-O23) \), and the lowest transition is \( LP2(O23) \rightarrow \sigma^*(C22-O44) \), observed to have 58.68 and 38.54 kcal/mol stabilization energy values, respectively.

In the case of 2c, the highest and the lowest \( \pi \rightarrow \pi^* \) transitions are \( \pi(C5-C36) \rightarrow \pi^*(C3-C4) \) and \( \pi(C3-C4) \rightarrow \pi^*(C27-C28) \) with stabilization energy values of 33.06 kcal/mol and 0.51 kcal/mol, respectively. Additionally, in \( \sigma \rightarrow \sigma^* \) transitions, 7.99 kcal/mol is seen as the uppermost energy in \( \sigma(C17-C21) \rightarrow \sigma^*(C11-N13) \), and \( \sigma(C24-O25) \rightarrow \sigma^*(C27-C29) \) displayed the slightest energy of 0.51 kcal/mol. Among the transitions including the lone pair (LP), the highest value of energy, i.e., 58.76 kcal/mol, is observed for transition \( LP2(O38) \rightarrow \sigma^*(C22-O23) \), while the transition \( LP2(O23) \rightarrow \sigma^*(C22-O38) \) articulated the lowest energy value, i.e., 38.52 kcal/mol.

Compound 2d exhibited a \( \pi(C5-C36) \rightarrow \pi^*(C3-C4) \) transition with the uppermost energy as 33.51 kcal/mol and \( \pi(N39-O40) \rightarrow \pi*(C32-C38) \) with the smallest stability value, i.e., 4.44 kcal/mol. The highest stabilization energy value among \( \sigma \rightarrow \sigma^* \) transitions for 2d is 8.09 kcal/mol observed in \( \sigma(C17-C21) \rightarrow \sigma^*(C11-N13) \), whereas the transition \( \sigma(C32-C38) \rightarrow \sigma^*(C38-N39) \) displayed the lowest energy value of 0.50 kcal/mol. The transition \( LP2(O42) \rightarrow \sigma^*(C22-O23) \) is observed with a maximum energy of 59.04 kcal/mol and \( LP2(O23) \rightarrow \sigma^*(C22-O42) \) with a minimum value of 38.50 kcal/mol.

The chromophore 2e showed the transition \( \pi(C1-C2) \rightarrow \pi^*(C3-C11) \) with a maximum stability value of 20.36 kcal/mol. The other \( \pi \rightarrow \pi^* \) transition, \( \pi(N26-O27) \rightarrow \pi^*(C20-C22) \), is observed with the lowest value, i.e., 1.79 kcal/mol. The \( \sigma \rightarrow \sigma^* \) transitions arise because the weaker transitions among \( \sigma \) (donor) and \( \sigma^* \) (acceptor) showed 3.49 kcal/mol as the maximum stability value in 2e occurring during \( \sigma(C16-C20) \rightarrow \sigma^*(C15-N29) \). The lowest value for the same transitions is 0.25 kcal/mol, observed in \( \sigma(S30-O32) \rightarrow \sigma^*(S30-C33) \). Some prominent LP transitions include \( LP1(N13) \rightarrow \pi^*(C12-C18) \) and \( LP2(O27) \rightarrow \sigma^*(N26-O28) \) with 21.74 and 11.31 kcal/mol energy values, respectively.

The study performed with MO6 displayed that, in compound 2a, \( \pi(C32-C38) \rightarrow \pi^*(C27-C29) \) displayed the maximum while \( \pi(C22-O23) \rightarrow \pi^*(C17-C21) \) presented the minimum stabilization energy values, i.e., 24.78 and 4.05 kcal/mol, respectively. The maximum stabilization energy among \( \sigma \rightarrow \sigma^* \) transitions perceived in 2a is 7.61 kcal/mol by \( \sigma(C17-C21) \rightarrow \sigma^*(C11-N13) \). Likewise, \( \sigma(C28-H31) \rightarrow \sigma^*(S24-C27) \) presented the lowest stabilization energy value of 0.51 kcal/mol. The transitions like \( LP2(O39) \rightarrow \pi^*(C22-O23) \) and \( LP2(O23) \rightarrow \sigma^*(C22-O39) \) are observed with maximal and minimal stability values of 48.46 and 34.65 kcal/mol, respectively.

In 2b, the \( \pi(C32-C34) \rightarrow \pi^*(C27-C29) \) transition showed the greatest value of stabilization energy, i.e., 30.73 kcal/mol. In addition, transitions like \( \pi(C22-O23) \rightarrow \pi^*(C17-C21) \) expressed the lowest value of 4.02 kcal/mol. Furthermore, the energy value of 7.55 kcal/mol is observed in \( \sigma(C17-C21) \rightarrow \sigma^*(C11-N13) \) as the largest value among \( \sigma \rightarrow \sigma^* \) transitions. The other electronic interaction, \( \sigma(S24-O25) \rightarrow \sigma^*(C27-C29) \), expressed the minimal stability as 0.53 kcal/mol. Among other transitions, the uppermost probable transition is \( LP2(O44) \rightarrow \pi^*(C22-O23) \) with a 48.30 kcal/mol energy value, and \( LP2(O23) \rightarrow \sigma^*(C22-O44) \) showed the lowest energy of 34.69 kcal/mol.

In 2c, the \( \pi(C5-C36) \rightarrow \pi^*(C3-C4) \) transition exhibited 23.70 kcal/mol and \( \pi(C3-C4) \rightarrow \pi^*(C29-C32) \), exhibited 0.54 kcal/mol, regarded as the highest and the lowest stabilization energies, respectively. Among \( \sigma \rightarrow \sigma^* \) transitions, 7.58 kcal/mol is noted as the largest stabilization value in \( \sigma(C17-C21) \rightarrow \sigma^*(C11-N13) \), and \( \sigma(S24-C27) \rightarrow \sigma^*(C28-H31) \) exhibited the lowest energy value of 0.52 kcal/mol. The highest stability (48.36 kcal/mol) is noted for transition \( LP2(O38) \rightarrow \pi^*(C22-O23) \) due to resonance. The transition \( LP2(O23) \rightarrow \sigma^*(C22-O38) \) expressed the lowest stability value of 34.66 kcal/mol.

The most important \( \pi \rightarrow \pi^* \) transitions in compound 2d are \( \pi(C32-C38) \rightarrow \pi^*(N39-O40) \) and \( \pi(N39-O40) \rightarrow \pi^*(C32-C38) \) and exhibited the highest and the lowest stabilization energy values, i.e., 24.42 and 4.01 kcal/mol, respectively. Amidst the weaker \( \sigma \rightarrow \sigma^* \) excitations, 7.67 kcal/mol is perceived as the greater value of energy shown in \( \sigma(C17-C21) \rightarrow \sigma^*(C11-N13) \), while \( \sigma(C15-H16) \rightarrow \sigma^*(N12-C14) \) displayed the lowest energy value of 0.50 kcal/mol. The excitation \( LP2(O42) \rightarrow \pi^*(C22-O23) \) is observed with a maximum energy of 48.59 kcal/mol, and \( LP2(O23) \rightarrow \sigma^*(C22-O42) \) showed the minimum value of 34.64 kcal/mol.

In the case of 2e, the transition with the utmost energy value is \( \pi(C1-C2) \rightarrow \pi^*(C3-C11) \), exhibiting 15.24 kcal/mol, while \( \pi(N26-O27) \rightarrow \pi^*(C20-C22) \) is the lowest energy transition of the same type, i.e., 1.60 kcal/mol. The energy value of 3.30 kcal/mol arising by much weaker interactions is perceived as a greater value in 2e for the \( \sigma(C16-C20) \rightarrow \sigma^*(C15-N29) \) transition, while the transition from \( \sigma(C20-C22) \rightarrow \pi^*(C22-N26) \) showed the smallest energy value of 0.25 kcal/mol. The electronic transition \( LP1(N13) \rightarrow \pi^*(C12-C18) \) is noted as the highest stability excitation with 18.19 kcal/mol, and \( LP2(O27) \rightarrow \sigma^*(N26-O28) \) with 10.33 kcal/mol exhibited the lowest value.

Overall data revealed that the delocalization of \( \pi \)-electrons plays a remarkable role in the stability of molecules. Therefore, we can assume the prolonged hyperconjugation is present in entitled compounds and plays a major role in their stabilization and provides an excellent NLO response.

**VIBRATIONAL ANALYSIS**

DFT investigations were conducted in order to understand the vibration bands associated with 2a–2e in the gas phase. The complete data at two levels of theory, i.e., CAM-B3LYP/6-311G(d,p) and M06/6-311G(d,p), were computed to examine the absorption bands and intensities related with specific vibrations, and the results are given in Tables S16–S25, while their experimental spectra are found in Figures S2, S6, S10, S14, and S18.

**C–H Stretching Vibration.** In 2a at the CAM-B3LYP level, the computed carbon–hydrogen (C–H) stretching modes occurred at 3281–3073 cm\(^{-1}\), which is in good harmony with the experimentally determined value, i.e., 3050 cm\(^{-1}\). The C–H stretching bands of the aromatic ring are shown as mixed symmetrical and antisymmetrical modes at 3233–3183 cm\(^{-1}\). The C–H stretching modes and other modes and their intensities are additionally determined at the lowest frequencies, as shown in Table S16. The rocking vibration modes are noted to be 1544–
1037 cm$^{-1}$ with experimental values at 1300–980 cm$^{-1}$ and wagging at 805 cm$^{-1}$, as displayed in Table S16. Similarly, in 2a at M06, the carbon–hydrogen (C–H) stretching vibrational mode is found at 3228–3024 cm$^{-1}$. However, the frequency mode at 3177–3024 cm$^{-1}$ is observed as mixed asymmetric and symmetric stretching of C–H. The computed rocking vibrations found in the range of 1595–1009 cm$^{-1}$ while wagging at 863–838 cm$^{-1}$ is shown in Table S21. The other C–H stretching modes are examined at 3280–3199 cm$^{-1}$, showing harmony with the experimental value (1570 cm$^{-1}$). At M06, the carbon–hydrogen stretching vibrational mode is found in the range of 1595–1009 cm$^{-1}$, as shown in Table S22. The symmetric and asymmetric modes of C–H bond in the methyl group. The rocking and wagging frequencies are obtained at 1555–1042 cm$^{-1}$, showing harmony with the experimental value (1570 cm$^{-1}$). At M06, the carbon–hydrogen (C–H) stretching vibrational mode is observed as mixed asymmetric and symmetric stretching of C–H, as shown in Table S22. The rocking and wagging vibrational frequencies are found at 1590–1015 cm$^{-1}$, and the experimentally determined frequency band is seen at 1570 cm$^{-1}$, as shown in Table S22. In 2c at CAM-B3LYP, the C–H stretching frequencies appear at 3275–3072 cm$^{-1}$, as shown in Table S18. In the aromatic ring, C–H stretching is shown in the symmetric and asymmetric modes of C–H at 3212–3146 cm$^{-1}$. The rocking and wagging frequencies are archived in the range of 1543–1039 cm$^{-1}$ and expressed a good relationship when compared with the experimental value (1310 cm$^{-1}$). Similarly, at M06, the carbon–hydrogen stretching vibrational mode at 3231–3024 cm$^{-1}$ and the vibrational band at 3177–3105 cm$^{-1}$ are observed as mixed symmetric and asymmetric stretching of C–H, as shown in Table S23. The C–H rocking frequency range is found at 1513–1092 cm$^{-1}$, while its experimental value was 1310 cm$^{-1}$ and wagging vibrational value was 861 cm$^{-1}$, given in Table S23. Similarly, in 2d and 2e at CAM-B3LYP, the C–H stretching modes are examined at 3280–3074 and 3255–3199 cm$^{-1}$, respectively, as shown in Tables S19 and S20. In the aromatic ring, the afore-mentioned vibrational modes for symmetric and asymmetric modes exist in the ranges of 3213–3148 and 3249–3199 cm$^{-1}$, respectively. These vibrational frequencies are in excellent correlation with their experimentally determined vibrational modes (see Figures S19 and S20). The other C–H stretching bands are also collected at low frequencies, as shown in Tables S19 and S20. The rocking frequencies are found to be at 1544–1039 and 1576–1058 cm$^{-1}$, respectively, for 2d and 2e. The experimental values for the above-mentioned frequencies are examined at 1200 and 922 cm$^{-1}$ as shown in Tables S19 and S20. At M06, the carbon–hydrogen stretching vibrational mode is noted in the range of 3234–3025 cm$^{-1}$. In the same manner, the mixed symmetric and asymmetric frequencies of the C–H mode are computed in the ranges of 3203–3108 and 3203–3156 cm$^{-1}$, accordingly (Tables S24 and S25). The rocking and wagging frequencies are found at 1512–1090 and 837 cm$^{-1}$, respectively.

**C–C Stretching Vibrations.** At CAM-B3LYP, the C–C stretching bands appeared in the range of 1685–1530 cm$^{-1}$ in 2a, 1676–1512 cm$^{-1}$ in 2b, 1685–1532 cm$^{-1}$ in 2c, 1715–1508 cm$^{-1}$ in 2d, and 1714–1520 cm$^{-1}$ in 2e, which showed good agreement with the experimental values as represented in Figures S2, S6, S10, S14, and S18, respectively. Nevertheless, at M06, the C–C stretching vibrations observed at 1660–1512 cm$^{-1}$ in 2a, 1655–1528 cm$^{-1}$ in 2b, 1661–1513 cm$^{-1}$ in 2c, 1718–1507 cm$^{-1}$ in 2d, and 1711–1555 cm$^{-1}$ in 2e are shown in Tables S21–S25.

**C–N Bands.** In 2a at CAM-B3LYP, the C–N stretching bands are seen at 1615, 1347, and 1248 cm$^{-1}$. The aforementioned vibrational modes are observed at 1611, 1349, and 1249 in 2b. Likewise, the C–N mode of 2c appeared at 1611, 1382, and 1247 cm$^{-1}$ (Tables S16–S18). These modes are observed at 1617, 1447, and 1247 cm$^{-1}$ in 2d, shown in Table S19. Similarly, modes are observed at 1640, 1308, and 1213 cm$^{-1}$ in 2d, shown in Table S20. However, in 2a at M06, the C–N stretching vibrations observed at 1631, 1318, and 1255 cm$^{-1}$ in 2b, 1593, 1332, and 1296 cm$^{-1}$ in 2c; 1598, 1366, and 1257 cm$^{-1}$ in 2d; and 1626, 1311, and 1241 cm$^{-1}$ in 2e are shown in Tables S21–S25. Good harmony is seen when compared with experimental absorption bands (see Figures S2, S6, S10, S14 and S18).

**C–O Bands.** In 2a at CAM-B3LYP, the C–O stretching modes are observed at 1827, 1381, and 1248 cm$^{-1}$ (Table S16). Moreover, the C–O stretching bands are noted at 1826, 1349, and 1249 cm$^{-1}$ in 2b (Table S17). Furthermore, in 2c the C–O stretching modes are seen at 1827, 1711, 1382, and 1247 cm$^{-1}$ (Table S18). The C–O stretching modes are examined at 1829, 1382, and 1247 cm$^{-1}$ in 2d (Table S19), and in 2e these vibrational bands are found at 1717, 1347, and 1213 cm$^{-1}$ (Table S20). Similarly, at M06, the C–C stretching vibrations observed at 1837, 1392, and 1255 cm$^{-1}$ in 2a; at 1832, 1328, and 1271 cm$^{-1}$ in 2b; at 1835, 1332, and 1232 cm$^{-1}$ in 2c; at 1838, 1330, and 1230 cm$^{-1}$ in 2d; and 1721, 1398, and 1241 cm$^{-1}$ in 2e are shown in Tables S21–S25. At both levels of theory, the experimental values showed good agreement with the
Theoretical values as represented in Figures S2, S6, S10, S14, and S18, respectively.

### OPTICAL ANALYSIS

UV–visible spectroscopy provides aid in understanding the types of transitions, leading to the arrangement of transitions and the potential of transport of charge in compounds.\(^\text{5,6,36}\) The excitations in absorption spectra of 2\(a\)–2\(e\) (Figure 3) were estimated by using TD-DFT analysis at two different levels of theory, i.e., CAM-B3LYP and M06. Six lower singlet–singlet transitions were examined utilizing TD-DFT analysis, and the absorbance spectra of 2\(a\)–2\(e\) are included in Figures S1, S5, S9, S13, and S17. Tables S26–S30 and S31–S35 present the computed transition energies \((\epsilon_{\text{max}})\), absorbance wavelengths \((\lambda_{\text{max}})\), oscillation strength \((\alpha)\), and transition type for each compound under investigation at CAM-B3LYP and M06, respectively.

The values of maximum absorbance for 2\(a\)–2\(e\) are found to be 275.355, 275.160, 290.927, 278.347, and 652.858 nm, accordingly, with the CAM-B3LYP functional. Similarly, the \(\lambda_{\text{max}}\) values calculated at the M06 level of theory are noted to be 300.260, 299.522, 317.095, and 428.611 nm, respectively. Their experimental absorbance spectra showed the maximum absorbance nearly at 305, 275, 309, 280, and 345 nm for 2\(a\)–2\(e\), respectively. These calculations disclosed that experimental results showed good harmony with the M06 functional and indicated it to be a suitable level for further investigation of these compounds. Therefore, by comparing the results at the M06 level, the highest absorption value is observed in 2\(e\) with the lowest transition energy value of 2.893 eV, which demonstrated it to be the most red-shifted compound among all entitled chromophores, while 2\(b\) and 2\(d\) are examined as the blue-shifted compounds with higher excitation energies of 4.139 and 4.140 eV, accordingly. Overall, the descending order of absorption values of molecules is 2\(e\) > 2\(c\) > 2\(a\) > 2\(b\) > 2\(d\).

Compound 2\(e\) with a lower excitation energy and greater \(\lambda_{\text{max}}\) might show an appealing NLO response.

### NONLINEAR OPTICAL (NLO) ANALYSIS

In the modern era, many fields like signal processing, optical switches, telecommunication technologies, and optical storage systems require intensive utilization of NLO substances.\(^\text{37}\) The objective of NLO is to explain the response of molecules to an applied electric field. The optical response is governed via electrical properties of the compound that are associated with nonlinear (hyperpolarizability, \(\beta\)) and linear (polarizability, \(\alpha\)) interactions. Nevertheless, determining the NLO properties of large delocalized \(\pi\)-systems utilizing the DFT approach is a substantial challenge. Nonlinearity in organic molecules is deeply linked to the functional property relationship, which can be modified synthetically by estimating the effect of different donor–acceptor molecules and modifying the structure of \(\pi\)-conjugated systems.\(^\text{38}\) Charge transport efficiency is consistently higher in substances with substantial NLO characteristics.\(^\text{39,40}\) The NLO response of the 2\(a\)–2\(e\) series of compounds was computed at two functionals [CAM-B3LYP/6-311G(d,p) and M06/6-311G(d,p)], and their results are presented in the Tables 2 and S37–S40, respectively.

The dipole polarizability \(\alpha\) explains the capacity of a compound to create an induced dipole moment when placed in an external electric field. Understanding this fundamental response attribute is crucial for explaining nonbonded interactions such as induction and dispersion among the molecules in condensed or cluster phases. Additionally, understanding the dipole polarizability is crucial for designing organic electro-optic (OPE) and NLO materials.\(^\text{41}\) Moreover, the contributions of tensors are quite significant as they allow the formation of well-separated spin-dependent traps and a mutual orientation of atomic polarization and light polarization. In our studied compounds, the significant contribution tensor is found to be \(\beta_{xx}\) (see Tables S37 and S39). At CAMB3LYP, the \(\alpha\) values of 2\(a\)–2\(e\) compounds are as follows: 168, 4.198, 4.614, 4.142, and 4.866 \times 10^{-23} \text{ esu}. At the M06 level, the values are 3.220, 4.331, 4.760, 4.287, and 5.379 \times 10^{-23} \text{ esu}, respectively. The linear polarizability response is found to be almost the same for both functionals, and the decreasing order is noted as 2\(e\) > 2\(c\) > 2\(b\) > 2\(d\) > 2\(a\). The dipole moment values are 4.15, 7.49, 6.27, 2.39, and 3.04 D for 2\(a\)–2\(e\), respectively. The largest value of the dipole moment, i.e., 7.49 D, is shown by compound 2\(b\), while 2\(d\) showed the smallest value, i.e., 2.33 D. The overall descending order for the values of the dipole moment is 2\(b\) > 2\(c\) > 2\(e\) > 2\(d\). The values of hyperpolarizability \((\beta_{\text{tot}})\) and its nine contributing tensors along \(x\), \(y\), and \(z\) directions are expressed in Tables S38 and S40. A literature survey has revealed that the \(\Delta\)E between the LUMO and HOMO affected the polarizability of the compounds. Generally, the molecules with a lower energy gap show large hyperpolarizability values.\(^\text{42,43}\)

In our synthesized compounds, 2\(e\) exhibited the highest hyperpolarizability response, i.e., 5.095 \times 10^{-29} and 2.0418 \times 10^{-28} \text{ esu}, while 2\(c\) exhibited the lowest values of hyperpolarizability, i.e., 5.029 \times 10^{-30} and 5.577 \times 10^{-30} \text{ esu} with the CAM-B3LYP and M06 functionals, respectively. All investigated compounds follow the given decreasing order of hyperpolarizability: 2\(e\) > 2\(a\) > 2\(b\) > 2\(d\) > 2\(c\) at CAM-B3LYP with a slightly different order at M06, i.e., 2\(e\) > 2\(d\) > 2\(a\) > 2\(b\) > 2\(c\). By comparing the results at both levels, M06 showed comparatively better results than CAM-B3LYP. A comparative analysis was also performed by utilizing the urea molecule, which is utilized as a standard compound \((\mu = 3.4 \text{ D}, \langle \alpha \rangle = 4.878 \times 10^{-23} \text{ esu})\), and \(\beta_{\text{tot}} = 0.3728 \times 10^{-30} \text{ esu})\). By making a comparison of the dipole moments between urea and 2\(a\)–2\(e\) compounds—1.29, 2.20, 1.83, 0.68, and 0.89 at CAM-B3LYP and 1.27, 2.21, 1.84, 0.7, and 0.89 at M06—the aforementioned compounds show greater \(\mu\) values than those of urea. For dipole polarizability, the above-mentioned compounds

### Table 2. Computed Dipole Moment, Linear Polarizability, and Hyperpolarizability of 2\(a\)–2\(e\)

| properties | 2\(a\) | 2\(b\) | 2\(c\) | 2\(d\) | 2\(e\) |
|------------|-------|-------|-------|-------|-------|
| \(\mu_{\text{tot}}^a\) | 4.15 | 7.49 | 6.24 | 2.33 | 3.04 |
| \(\langle \alpha \rangle^a\) | 3.168 \times 10^{-23} | 4.198 \times 10^{-23} | 4.614 \times 10^{-23} | 4.142 \times 10^{-23} | 4.866 \times 10^{-23} |
| \(\beta_{\text{tot}}^a\) | 6.037 \times 10^{-30} | 5.782 \times 10^{-30} | 5.029 \times 10^{-30} | 5.577 \times 10^{-30} | 5.095 \times 10^{-29} |
| \(\mu_{\text{tot}}^b\) | 4.34 | 7.52 | 6.27 | 2.39 | 3.046 |
| \(\langle \alpha \rangle^b\) | 3.220 \times 10^{-23} | 4.331 \times 10^{-23} | 4.760 \times 10^{-23} | 4.287 \times 10^{-23} | 5.379 \times 10^{-23} |
| \(\beta_{\text{tot}}^b\) | 5.812 \times 10^{-30} | 5.637 \times 10^{-30} | 5.577 \times 10^{-30} | 9.230 \times 10^{-30} | 2.0418 \times 10^{-28} |

\(^a\text{CAM-B3LYP.} \)\(^b\text{M06, dipole moment in Debye while } \langle \alpha \rangle \text{ and } \beta_{\text{tot}} \text{ are in esu.} \)
showed a comparable response, while for first-order hyper-polarizability, the expressed 16.1, 16.5, 13.4, 15 and 137 at CAM-B3LYP and 15.5, 15.1, 14.9, 24.7, and 54.77 with the M06 functional show a greater NLO response than that of urea molecule. Interestingly, a more appealing NLO response is studied for prepared compounds than that for the urea molecule, which indicated their significance as used in photonic material.

Natural bond orbital (NBO) charges can help to explain the phenomenon of electronegativity balancing, kinetics of atomic charge mechanisms, and electrostatic potential on the external surface of structures. The structure and bonding efficiency of molecules are significantly influenced by atomic electrical charges. The electronic density over the aromatic ring is uneven in the existence of sufficient electronegative elements like O and N in the designed compounds, in accordance with Mulliken population data. The objective of utilizing a quantum chemical methodology is to accurately explain the electron distributions throughout the different chromophores and to predict the reactivity of the represented charges.

As shown by Figure S22, Mulliken atomic charges of 2a–2e are computed via CAM-B3LYP/6-311G(d,p) and M06/6-311G(d,p) approaches with the basis set, and the data are presented in Figure S22. Mulliken population analysis suggests that there is no variation in charge distribution throughout all hydrogen atoms. The sulfur atoms of SO₂, nitrogen atoms of NO₂, and some carbon of the benzene ring possess high positive charges because of the resonance effect. Whereas oxygen atoms are possessed by −COOCH₃ and −OCH₃ of the imidazole ring and carbon atoms of benzene rings holding −COOCH₃ and −OCH₃ groups possess high negative charges due to their highly electronegative nature.

**CONCLUSION**

In this study, novel N-1-sulfonyl substituted derivatives (2a–2e) with the D−π−A framework are synthesized, and their NLO behavior is explored. The efficient electron withdrawing acceptors are utilized for their structural tailoring, which strengthened the charge transfer phenomena. Different spectroscopic techniques, UV−visible, FTIR, and ¹H and ¹³C NMR, are utilized for the determination of structural characterization. Besides the synthesis, a computational study was also performed in order to explore the NLO characteristics of 2a–2e. FMO analysis explained the effective intramolecular charge transfer (ICT) of molecules. The NBO results depicted the development of a charge separation state owing to the effective transference of electrons in the π-conjugated schemes of 2a–2e. The UV−visible analysis proved compound 2e to be the most red-shifted among all other synthesized compounds, having a reduced energy gap. Further, global reactivity parameters (GRPs) findings support the FMO and UV−vis investigations as a higher value of softness is seen for this molecule, elucidating it as a more reactive compound. Therefore, the efficient linear and nonlinear response ((α) = 4,866 × 10⁻²³ and 5,379 × 10⁻²³ esu while β₀ − 5.095 × 10⁻²⁵ and 2.0418 × 10⁻²⁵ esu) is also studied for this molecule. This NLO study has illustrated the N-1-sulfonyl substituted derivatives as excellent materials for researchers to disclose advanced applications in optoelectronics and the telecommunication sector.

**EXPERIMENTAL PROCEDURE**

**Substrate and Reagents.** Benzaldehyde (Applichem, Germany), 3,4-diaminobenzoic acid, ethanol, tetra-hydrofuran (THF) 99%, sulfuric acid 98%, nickel acetate (Merck, Germany), methanol, chloroform, n-hexane, dichloromethane (Riedel-de-Haen, Germany) and sodium hydride, 4-nitrobenzenesulfonyl chloride 97%, 4-chlorobenzenesulfonyl chloride, 4-methoxybenzenesulfonyl chloride 97%, 2-naphthalenesulfonyl chloride 99% (Sigma-Aldrich, USA) were of high purity grade and used as received.

**Instrumentation.** The progress and purity of the reaction was monitored using precoated silica gel 60 F₂₅₄ aluminum thin layer chromatographic sheets (Merck, Germany). Melting points were determined with an A&E Lab (UK) melting point apparatus and are uncorrected. To determine the characteristic functional groups in the compounds, infrared spectra were recorded on a Shimadzu Nicolet iS10 FT-IR spectrophotometer. ¹H and ¹³C NMR spectra were recorded on a Bruker Avance 300 MHz spectrometer.

**General Procedure for the Synthesis of N-1-Sulfonyl Substituted Derivatives of 2-Substituted Benzimidazoles (2a–2e).** The respective 2-substituted benzimidazoles (0.2 g, 0.01 mmol) and sodium hydride (1.0 equiv) were dissolved in THF solvent, and the temperature of the reaction mixture was maintained between 5 and 10 °C. The reaction mixture was stirred for 30 min. Then, respective arylsulfonyl chloride (1.20 equiv) was added, and reaction mixture was left for 24 h on stirring at room temperature. The progress of the reaction was continuously monitored by taking TLC (n-hexane/ethyl acetate, 3:2) after every 1 h. Upon completion, the reaction mixture was poured on ground ice. The product was extracted via solvent extraction using dichloromethane solvent, and the organic layer was separated. The solvent was evaporated under a high vacuum to obtain a dried product. Finally, the purity of the synthesized compounds was ascertained by recrystallization in ethanol.

**Methyl 1-(4-Chlorophenylsulfonyl)-2-phenyl-1H-benzo[d]imidazole-6-carboxylate (2a).** Light brown shiny solid. Yield: 60%. Melting point: 167—168 °C. Rᵡ 0.52 (n-hexane/ethyl acetate; 3:2). IR (ATR, cm⁻¹): 2950 (C–H aliphatic stretching), 1708 (C=O stretching), 1570 (C=C stretching), 1530–1420 (C=C aromatic ring stretching). ¹H NMR (300 MHz, DMSO-d₆): δ 3.84 (3H, s, −CH₂ ester), 7.02 (2H, d, Ar–H, J = 6.7 Hz), 7.20 (3H, m, Ar–H), 7.56 (2H, m, Ar–H), 7.75 (2H, d, Ar–H, J = 7.8 Hz), 7.84 (1H, d, Ar–H, J = 8.4 Hz), 7.92 (1H, dd, Ar–H, J = 8.4, 1.5 Hz), 8.11 (1H, s, Ar–H). ¹³C NMR (75 MHz, DMSO-d₆): 52.6 (−CH₂ ester), 113.5, 119.6, 124.0, 124.5, 126.4, 127.9, 128.1, 129.4, 129.6, 129.7, 130.9, 136.0, 137.0, 142.6, 156.6 (Ar–C), 166.9 (C=O).

**Methyl 1-(4-Methoxyphenylsulfonyl)-2-phenyl-1H-benzo[d]imidazole-6-carboxylate (2b).** Light brown solids. Yield: 66%. Melting point: 173—174 °C. Rᵡ 0.50 (n-hexane/ethyl acetate, 3:2). IR (ATR, cm⁻¹): 2943 (C–H aliphatic stretching), 1705 (C=O stretching), 1562 (C=C stretching), 1516–1442 (C=C aromatic ring stretching). ¹H NMR (300 MHz, DMSO-d₆): δ 3.84 (3H, s, −CH₂ ester), 7.09 (2H, d, Ar–H, J = 6.7 Hz), 7.28 (3H, m, Ar–H), 7.53 (2H, m, Ar–H), 7.75 (2H, d, Ar–H, J = 7.8 Hz), 7.84 (1H, d, Ar–H, J = 8.4 Hz), 7.92 (1H, dd, Ar–H, J = 8.4, 1.5 Hz), 8.10 (1H, s, Ar–H). ¹³C NMR (75 MHz, DMSO-d₆): 52.6 (−CH₂ ester), 55.6 (−OCH₃), 113.2, 113.6, 124.2, 124.6, 126.4, 127.5, 128.1, 129.4, 129.6, 131.1, 135.9, 136.9, 145.6, 156.5 (Ar–C), 166.9 (C=O).

**Methyl 1-(Naphthalen-2-ylsulfonyl)-2-phenyl-1H-benzo[d]imidazole-6-carboxylate (2c).** Black solid. Yield: 60%. Melting point: 86—87 °C. Rᵡ 0.48 (n-hexane/ethyl acetate; 3:2). IR (ATR, cm⁻¹): 2916 (C–H aliphatic stretching), 1716
(C=O stretching), 1581 (C–N stretching), 1543–1435 (C=C aromatic ring stretching). 1H NMR (300 MHz, DMSO-d6): δ 3.80 (3H, s, −CH3 ester), 7.30 (1H, m, Ar–H), 7.40 (4H, m, Ar–H), 7.50 (4H, m, Ar–H), 7.80 (2H, d, Ar–H, J = 8.7 Hz), 7.90 (1H, d, Ar–H, J = 6.9 Hz), 8.00 (1H, s, Ar–H), 8.20 (1H, s, Ar–H), 8.28 (1H, s, Ar–H). 13C NMR (75 MHz, DMSO-d6): δ 52.4 (−CH3 ester), 113.3, 139.6, 123.8, 123.9, 124.3, 126.3, 127.2, 128.0, 129.0, 129.1, 129.3, 129.5, 129.7, 129.9, 130.5, 130.9, 133.3, 154.2 (Ar–C), 167.1 (C=O).

**Methyl 1-(4-Nitrophenylsulfonyl)-2-phenyl-1H-benzo[d]-imidazole-6-carboxylate (2d).** Brown solid. Yield: 45%. Melting point: 130–131 °C. Rf: 0.49 (n-hexane/ethyl acetate, 3:2). IR (ATR, cm⁻¹): 2930 (C–H aliphatic stretching), 1720 (C=O stretching), 1585 (C–N stretching), 1531–1443 (C=C aromatic ring stretching). 1H NMR (300 MHz, DMSO-d6): δ 5.20 (3H, s, −CH3 ester), 6.05 (1H, s, Ar–H), 6.84 (1H, d, Ar–H, J = 8.7 Hz), 6.94 (1H, m, Ar–H), 7.73 (1H, m, Ar–H), 8.18 (4H,m, Ar–H), 8.51 (4H, m, ArH). 13C NMR (75 MHz, DMSO-d6): δ 52.0 (−CH3 ester), 115.4, 116.5, 116.9, 125.3, 131.0, 133.2, 134.4, 141.3, 151.5, 152.8 (Ar–C), 165.0 (C=O).

6-Nitro-2-(4-nitrophenyl)-1-(4-nitrophenylsulfonyl)-1H-benzo[d]imidazole (2e). Brown solid. Yield: 45%. Melting point: 232–233 °C. Rf: 0.65 (n-hexane/ethyl acetate, 1:1). IR (ATR, cm⁻¹): 3030 (C–H aliphatic stretching), 1665 (C–N stretching), 1531–1442 (C=C aromatic ring stretching). 1H NMR (300 MHz, DMSO-d6): δ 6.67 (1H, d, Ar–H, J = 8.7 Hz), 7.62 (1H, d, Ar–H, J = 9.0 Hz), 7.78 (1H, d, Ar–H, J = 9.0 Hz), 7.88 (1H, d, Ar–H, J = 8.7 Hz), 7.97 (1H, s, Ar–H), 8.04 (1H, dd, Ar–H, J = 2.4 Hz), 8.13 (1H, dd, Ar–H, J = 2.1 Hz), 8.27 (1H, d, Ar–H, J = 8.7 Hz), 8.45 (3H, m, Ar-H). 13C NMR (75 MHz, DMSO-d6): δ 113.9, 116.1, 117.8, 118.9, 124.7, 125.0, 128.5, 128.9, 129.5, 135.3, 143.5, 148.8, 153.9, 162.7 (Ar–C).

**Computational Study.** The quantum chemical analysis for all of the synthesized compounds was conducted using the Gaussian 09 package program with the CAM-B3LYP/6-311G (d,p) and M06/6-311G(d,p) functionals. Avogadro, the Gaussian View 5.0 package, and Chemcraft were utilized for various DFT and TDDFT computations along with some graphical displays of studied compounds. These investigations included UV–vis, vibrational, and 1H and 13C NMR techniques and the frontier molecular orbital (FMO), natural bond orbital (NBO), global reactivity parameters (GRPs), and nonlinear optical (NLO) response of imidazole-based molecules. The stabilization energy calculations of the entitled compounds were confirmed via NBO analysis and second-order perturbation theory, respectively, with the aid of the program package NBO 3.1.52–54 By utilizing the energies of FMOs, global reactivity parameters (GRPs) were calculated. The NLO parameters, i.e., dipole moment (μ), linear polarizability (α) and first order hyperpolarizability (βαβ) of the title compounds were also computed by utilizing eqs S8–S10.

Supporting Information

The Supporting Information is available free of charge at https://pubs.acs.org/doi/10.1021/acsomega.2c02805.

Spectroscopic Data: UV, FT-IR, 1H and 13C NMR spectra of all synthesized compounds. Computational studies: frontier molecular orbitals (FMOs) of all synthesized compounds at M06/6-311G(d,p). Natural Bond Orbital (NBO) Investigations: second order perturbation theory analysis of Fock matrix in NBO of all synthesized compounds at CAM-B3LYP/6-311G(d,p). Second order perturbation theory analysis of Fock matrix in NBO of all synthesized compounds at M06/6-311G(d,p). UV–vis Analysis: wavelength, excitation energy, and oscillator strength of all investigated synthesized compounds at CAM-B3LYP/6-311G(d,p) in ethanol. Wave-length, excitation energy, and oscillator strength of all investigated synthesized compounds at M06/6-311G(d,p) in ethanol. Nonlinear Optics: dipole polarizability and major contributing tensor (α) of all studied compounds at CAM-B3LYP/6-311G(d,p). Computed first hyperpolarizabilities (βαβ) and major contributing tensor (α) of all studied compounds at CAM-B3LYP/6-311G(d,p). Computed first hyperpolarizabilities (βαβ) and major contributing tensor (α) of all studied compounds at M06/6-311G(d,p).
