SMOOTH PERFECTNESS THROUGH DECOMPOSITION OF
DIFFEOMORPHISMS INTO FIBER PRESERVING ONES.

STEFAN HALLER, JOSEF TEICHMANN

Abstract. We show that on a closed smooth manifold $M$ equipped with $k$
fiber bundle structures whose vertical distributions span the tangent bundle,
every smooth diffeomorphism $f$ of $M$ sufficiently close to the identity can
be written as a product $f = f_1 \cdots f_k$, where $f_i$ preserves the $i^{th}$-fiber. The
factors $f_i$ can be chosen smoothly in $f$. We apply this result to show that on
a certain class of closed smooth manifolds every diffeomorphism sufficiently
close to the identity can be written as product of commutators and the factors
can be chosen smoothly. Furthermore we get concrete estimates on how many
commutators are necessary.

1. Introduction

We are concerned with the question of perfectness of diffeomorphism groups
on compact manifolds. It is well known that the $e$-components of diffeomorphism
groups on compact smooth manifolds are perfect by results of Herman [Her73],
Thurston [Thu74], Mather [Mat74, Mat75] and Epstein [Eps84]. However, the
questions, how many commutators are necessary to represent a given smooth dif-
feomorphism $f$ via

$$f = [h_1, g_1] \cdots [h_n, g_n]$$

and if these commutators can be chosen smoothly in $f$, remains open. Only in the
case of the torus $T^n$ the result of Herman provides the concrete, positive answer by
a beautiful small denominator argument.

We shall provide concrete, positive answers for both questions in a subclass of all
compact smooth manifolds by a decomposition theorem (section 2) and applications
of some canonical exponential laws ("parameterization of diffeomorphisms"). In
particular the odd dimensional spheres $S^{2n+1}$ can be treated, which led us - in
view of the applied methods - to the title of our article.

2. Inverse Function Theorems

We shall apply Nash–Moser inverse function theorems in the spirit of Richard
Hamilton, see [Ham82] for all necessary details, where the theory of tame spaces and
the tame inverse function theorems are presented. Given graded Fréchet spaces $E$
and $F$, i.e. we are additionally given an increasing sequence of seminorms \( \{p_n\}_{n \geq 0} \)

on $E$ and $\{q_n\}_{n \geq 0}$ on $F$, then a tame estimate for a linear map $L : E \to F$ is given by

$$q_n(Le) \leq C_n p_{n+r}(e)$$

for a given basis $b$ and the (tame) degree $r$ for all $n \geq b$ and $e \in E$. In particular such a map is continuous, we shall call them tame linear maps. A linear isomorphism $L : E \to F$ is called a tame isomorphism if $L$ and $L^{-1}$ satisfy tame estimates. To prove the inverse function theorem we need to work on tame Fréchet spaces: a tame Fréchet space is a graded Fréchet space, which is a tame direct summand of a space $\Sigma(B)$, the Fréchet space of all very fast falling sequences in a Banach space $B$. Let $E$ and $F$ be graded Fréchet spaces and $P : E \supseteq U \to F$ be a map, then $P$ satisfies a tame estimate if

$$q_n(P(e)) \leq C_n(1 + p_{n+r}(e))$$

for a given basis $b$ and the (tame) degree $r$ for all $n \geq b$ and $e \in U$. We shall call such maps tame maps. Clearly a mapping is tame linear if it is tame and linear. For mappings on products we can define tame degrees for any term in the product, which is useful in applications. We shall work in the category $\mathcal{T}$, whose objects are open subsets of tame spaces and whose morphisms the smooth tame maps, i.e. mappings such that all derivatives are tame. The Nash–Moser inverse function theorems will be stated in this category. By means of the tame category we can define tame manifolds, bundles and geometric or algebraic structures.

The inverse function theorem finally reads as follows in its general version in $\mathcal{T}$, see [Ham82] for both theorems and all necessary details.

**Theorem 1.** Let $E$ and $F$ be tame spaces and $P : E \supseteq U \to F$ be a smooth tame map. Suppose that the equation $DP(e)h = f$ has a unique solution $h = VP(e)f \in E$ for all $e \in U$ and all $f \in F$ and that the family of inverses $VP : U \times F \to E$ is smooth tame, then $P$ is locally invertible and the inverse is a smooth tame map.

We shall apply the version for right inverses.

**Theorem 2.** Let $E$ and $F$ be tame spaces and $P : E \supseteq U \to F$ be a smooth tame map. Suppose that the equation $DP(e)h = f$ has a solution $h = VP(e)f \in E$ for all $e \in U$ and all $f \in F$ and that the family of right inverses $VP : U \times F \to E$ is smooth tame, then $P$ is locally surjective and admits a smooth tame local right inverse.

### 3. The Decomposition Theorem

In this section we shall prove the fundamental decomposition theorem, which allows a “smooth” decomposition of a small diffeomorphism on a compact manifold into more regular parts. This shall be applied in the following sections to obtain perfectness results on Fréchet–Lie groups such as $\text{Diff}(S^{2n+1})$.

Let $M$ be a closed connected manifold such that there exist $k$ fiber bundle structures $S_i \hookrightarrow M \xrightarrow{p_i} B_i$, for $1 \leq i \leq k$ with connected fibers $S_i$ and (involutive) vertical distribution $D_i$, which is a subbundle of $TM$. We suppose that the distributions $D_i$ span $TM$, however they need not be linearly independent.\footnote{Note, that if $M$ appears as the total space of a fiber bundle $S \hookrightarrow M \xrightarrow{p} B$ and $\dim S \geq 1$, then one can always perturb $p$ to obtain finitely many fiber bundles $S \hookrightarrow M \xrightarrow{p_i} B$, which satisfy this condition.} We denote
In view of the implicit function theorem it suffices to construct a smooth tame right inverse of the sum. On $U$ we choose a local frame $X^1, \ldots, X^n$ such that for all $i \in \mathcal{I}$ the condition $f_i \circ \cdots \circ f_1 \circ \mathcal{D}_i(x) \subset U$ holds and such that

$$\mathcal{S}(f_1, \ldots, f_k) := (f_2^* \cdots f_k^* X_{n_1}, \ldots, f_2^* \cdots f_k^* X_{m_1}, f_3^* \cdots f_k^* X_{n_2}, \ldots, X_n)$$

The smooth tame mapping

$$P : \text{Diff}_1(M) \times \cdots \times \text{Diff}_k(M) \to \text{Diff}(M)$$

$$(f_1, \ldots, f_k) \mapsto f_1 \circ \cdots \circ f_k$$

admits a smooth tame local right inverse at the identity $e \in \text{Diff}(M)$.

Proof. In the right trivialization of the tangent bundles of the respective Lie groups we are given a mapping:

$$\bar{T}P : \prod_{i=1}^k \text{Diff}_i(M) \times \prod_{i=1}^k \Gamma(D_i) \to \prod_{i=1}^k \text{Diff}_i(M) \times \Gamma(TM)$$

$$(f_1, \ldots, f_k; \xi_1, \ldots, \xi_k) \mapsto (f_1, \ldots, f_k; f_2^* \cdots f_k^* \xi_1 + f_3^* \cdots f_k^* \xi_2 + \cdots + \xi_k)$$

In view of the implicit function theorem it suffices to construct a smooth tame right inverse of $\bar{T}P$, linear in the variables $\xi_i$. We solve the problem locally: First we choose a covering $\mathcal{U}$ of open subsets of $M$ such that for $U \in \mathcal{U}$ the bundles $TM|_U$ and $\mathcal{D}_i|_U$ are trivial and that a compatible local frame (see below) exists. Second we choose a finite partition of unity $\{\eta_U\}_{U \in \mathcal{U}}$ subordinated to this covering. The associated projection

$$p : \Gamma(TM) \to \bigoplus_{U \in \mathcal{U}} \Gamma_V(TM|_U)$$

$$p_U(X) = \eta_U X$$

where $\Gamma_V$ denotes the sections with support in the closed set $V$ and $V$ is the support of $\eta_U$ in $U$, is a right inverse of the sum. On $U \in \mathcal{U}$ we can solve the equation locally. We choose a local frame $X^1, \ldots, X^n$ where $n = \dim M$, compatible with the distribution on $U$, i.e. there are integers $0 = m_0 \leq m_1 \leq \cdots \leq m_k = n$, such that

$$\mathcal{D}_i(x) = (X^{m_i}(x), \ldots, X^{m_i}(x)) \text{ for all } x \in U,$$

where we set $n_i := m_{i-1} + 1$. We assume furthermore that the vector fields $X^i$ are globally defined on $M$. We then choose an open neighborhood $V_i$ of $e \in \text{Diff}_i(M)$ such that for all $f_i \in V_i$ the condition $f_i \circ \cdots \circ f_1 \circ \mathcal{D}_i(x) \subset U$ holds and such that

$$\mathcal{S}(f_1, \ldots, f_k) := (f_2^* \cdots f_k^* X_{n_1}, \ldots, f_2^* \cdots f_k^* X_{m_1}, f_3^* \cdots f_k^* X_{n_2}, \ldots, X_n)$$
is a frame for $TM$ on $V$. Given $Y \in \Gamma(V(TM|U))$, we define a section $s_{i,U}$ via the decomposition on the frame $\mathfrak{g}(f_1, \ldots, f_k)$ by the following formula

$$s_{i,U}(Y) := (f_{i+1}^* \cdots f_k^*)^{-1}\left(\sum_{j=n_i}^{m_i} a_j(Y) f_{i+1}^* \cdots f_k^* X_j\right)$$

where

$$Y = \sum_{i=1}^{k} \sum_{j=n_i}^{m_i} a_j(Y) f_{i+1}^* \cdots f_k^* X_j.$$  

The functions $a_j$ are smooth with support in $V$, so $s_{i,U}(Y)$ has support in $U$ and consequently the section defines an element of $\Gamma(D_i)$ by construction. The pullbacks depend tame on the diffeomorphism and the module structure is tame, hence the functions $a_j$ depend tame on the diffeomorphisms $f_{i+1}, \ldots, f_k$ and the vector field $Y$. Consequently the mapping

$$\prod_{i=1}^{k} V_i \times \Gamma(TM) \to \prod_{i=1}^{k} \text{Diff}_{i}(M) \times \prod_{i=1}^{k} \Gamma(D_i)$$

$$(f_1, \ldots, f_k; X) \mapsto (f_1, \ldots, f_k; \sum_{U \in \Omega} s_{1,U}(\eta_U X), \ldots, \sum_{U \in \Omega} s_{k,U}(\eta_U X))$$

is the desired smooth tame right inverse of $\tilde{TP}$.

4. Perfectness of fiber-preserving Diffeomorphisms

In this section we introduce notions of perfectness on regular Lie groups, namely global, semi infinitesimal and infinitesimal smooth perfectness. The relations between these notions become complicated on the level of Fréchet–Lie groups, even though natural inequalities remain valid. These notions are finally applied to “parametrized” families of diffeomorphisms, which is an application of cartesian closedness, see for example [KM97].

All manifolds, Lie groups and Lie algebras are supposed to be smooth and modeled on convenient vector spaces. This includes all Fréchet manifolds, Fréchet–Lie groups and Fréchet–Lie algebras. We moreover assume, that the Lie groups are regular, in particular they admit a smooth exponential mapping. This is not too much a restriction, since “all known convenient Lie groups are regular”, cf. [KM97]. Conditions for regularity of convenient Lie groups can be found in [Omo97], [Tei01].

**Definition 1.** For a Lie group $G$ we define $N_G \in \mathbb{N}$ to be the smallest integer $N$, such that for every open neighborhood $e \in U \subseteq G$ their exist $h_i = \exp(Y_i) \in U$, an open neighborhood $e \in V \subseteq G$ and smooth mappings $S_i : V \to G$ with $S_i(e) = e$ and

$$[S_1(g), h_1] \cdots [S_N(g), h_N] = g, \quad \text{for all } g \in V.$$  

Equivalently, $N_G$ is the smallest integer $N$, such that for every open neighborhood $e \in U \subseteq G$ there exist $h = \exp(Y) \in U^N$ with, such that the map

$$s_h : G^N \to G, \quad (g_1, \ldots, g_N) \mapsto [g_1, h_1] \cdots [g_N, h_N]$$

has a smooth local right inverse $S$ with $S(e) = (e, \ldots, e)$. If such an integer does not exist we set $N_G := \infty$. We call the Lie group $G$ smoothly perfect if $N_G < \infty$. 

Definition 2. For a Lie group $G$ with Lie algebra $\mathfrak{g}$ we define $N^\text{Ad}_G \in \mathbb{N}$ to be the smallest integer $N$, such that for every open neighborhood $e \in U \subseteq G$ their exist $h_i = \exp(Y_i) \in U$ and bounded linear maps $s_i : \mathfrak{g} \to \mathfrak{g}$ with

$$(\text{id} - \text{Ad}_{h_i})s_1(X) + \cdots + (\text{id} - \text{Ad}_{h_N})s_N(X) = X \quad \text{for all } X \in \mathfrak{g}.$$ 

Equivalently, $N^\text{Ad}_G$ is the smallest integer $N$, such that for every open neighborhood $e \in U \subseteq G$ there exist $h = \exp(Y) \in U^N$ and a bounded linear right inverse $s : \mathfrak{g} \to \mathfrak{g}^N$ of the map $T_{(e, \ldots, e)}\kappa_h : \mathfrak{g}^N \to \mathfrak{g}$. If such an integer does not exist we set $N^\text{Ad}_G := \infty$.

Remark 1. It would be more natural to claim existence of arbitrary, small $h_i$, not only those which are exponentials, however, in this general case we do not get the desired “natural” inequalities, cf. Lemma 1 below.

Definition 3. For a Lie algebra $\mathfrak{g}$ we define $N_\mathfrak{g} \in \mathbb{N}$ to be the smallest integer $N$, such that there exist $Y_i \in \mathfrak{g}$ and bounded linear maps $\sigma_i : \mathfrak{g} \to \mathfrak{g}$ with

$$[\sigma_1(X), Y_1] + \cdots + [\sigma_N(X), Y_N] = X, \quad \text{for all } X \in \mathfrak{g}.$$ 

Equivalently $N_\mathfrak{g}$ is the smallest integer $N$, such that there exist $Y \in \mathfrak{g}^N$ and a bounded linear right inverse $\sigma : \mathfrak{g} \to \mathfrak{g}^N$ of the mapping

$$K_Y : \mathfrak{g}^N \to \mathfrak{g} , \quad K_Y(X_1, \ldots, X_N) := [X_1, Y_1] + \cdots + [X_N, Y_N].$$

If such an integer does not exist we set $N_\mathfrak{g} := \infty$.

Lemma 1. For any Lie group $G$ with Lie algebra $\mathfrak{g}$ one has $N_\mathfrak{g} \leq N^\text{Ad}_G \leq N_G$. If $G$ is a Banach–Lie group one even has $N_\mathfrak{g} = N^\text{Ad}_G = N_G$.

Proof. $N^\text{Ad}_G \leq N_G$ follows immediately from differentiating $\kappa_h \circ S = \text{id}$ at $e \in G$, i.e. one can take $s = T_e S$. If $G$ is a Banach–Lie group then the implicit function theorem shows $N^\text{Ad}_G \geq N_G$. Notice, that every $h$ sufficiently close to the identity is in the image of the exponential map, for the latter is a local diffeomorphism on Banach–Lie groups.

Next we show $N_\mathfrak{g} \leq N^\text{Ad}_G$. For $Y \in \mathfrak{g}$ we have $\frac{\partial}{\partial t} \text{Ad}_{\exp(tY)} = \text{ad}_Y \circ \text{Ad}_{\exp(tY)}$. Integration immediately yields

$$\text{id} - \text{Ad}_h = -\text{ad}_Y \circ \int_0^1 \text{Ad}_{\exp(tY)} \, dt,$$

where $h = \exp(Y)$. Inserting the bounded linear right inverse $s$ for $T_{(e, \ldots, e)}\kappa_h$, we obtain a bounded linear right inverse $\sigma = (\int_0^1 \text{Ad}_{\exp(tY)} \, dt \circ s_i)_{i=1, \ldots, N^\text{Ad}_G}$ for $K_Y$.

Suppose $G$ is a Banach–Lie group. We want to show $N_\mathfrak{g} \geq N^\text{Ad}_G$. Choose $Y \in \mathfrak{g}^{N_\mathfrak{g}}$, such that $K_Y$ has a bounded linear right inverse and choose a smooth curve $h_t \in U^{N_\mathfrak{g}}$ with $h_0 = (e, \ldots, e)$ and $h_0 = Y$. For $t > 0$ consider the maps $K_t := \frac{1}{t}T_{(e, \ldots, e)}\kappa_{h_t}$ and note, that $\lim_{t \to 0} K_t = K_Y$. Since $\mathfrak{g}$ is a Banach space, the space of bounded linear mappings $\mathfrak{g}^{N_\mathfrak{g}} \to \mathfrak{g}$ which admit a bounded linear right inverse is open, hence for $t$ sufficiently small $K_t$ has a bounded linear right inverse and thus $T_{(e, \ldots, e)}\kappa_{h_t} = tK_t$ as well, i.e. $N_\mathfrak{g} \geq N^\text{Ad}_G$.

Example 1. For a finite dimensional perfect Lie group $G$ one has $1 < N_G \leq \dim G$. For any finite dimensional Lie algebra one has $N_\mathfrak{g} > 1$, since $\text{ad}_Y : \mathfrak{g} \to \mathfrak{g}$ can’t be surjective, for it has a non-trivial kernel. Moreover obviously $N_\mathfrak{g} \leq \dim \mathfrak{g}$. 

\section*{Smooth Perfectness of Diffeomorphisms}

5
Example 2. If $G$ is complex semisimple or real semisimple and split or real semisimple and compact then $N_G = 2$. Indeed, if $G$ is complex for example, choose $H$ to be a regular element in the Cartan subalgebra $\mathfrak{h}$ and $\rho := \sum \alpha E_\alpha$, where the sum is over all simple roots and $E_\alpha$ denotes a non-zero element of the root space of $\alpha$. Then $\text{ad}_H(g) = h^\perp$ and $\text{ad}_\rho(g) \supseteq h$, hence $\text{ad}_H + \text{ad}_\rho : g \times g \to g$ is onto. In the two real cases one can argue similarly.

The first non-trivial example is an immediate consequence of a theorem due to Herman, cf. [Her73].

Example 3. For the torus $T^n$ one has $N_{\text{Diff}(T^n)} \leq 3$. Indeed, Herman proves the statement with one commutator up to multiplication by an element in $T^n$. Since $T^n \subseteq \text{PSL}(2,\mathbb{R})^n$ and $\text{PSL}(2,\mathbb{R})^n$ is real semisimple and split example 2 shows that $N_{\text{Diff}(T^n)} \leq 3$.

The base of all bundles we shall consider below is understood to be a compact, smooth and finite dimensional manifold, but the fiber might be infinite dimensional.

Definition 4. Let $\pi : E \to B$ be a fiber bundle with typical fiber $F$, whose structure group is reduced to $K \subseteq \text{Diff}(F)$, i.e. we have given a fiber bundle atlas whose transition functions take values in $K \subseteq \text{Diff}(F)$, where $K$ is any subgroup of $\text{Diff}(F)$.

We define $C_E = C_E^K$ to be the smallest integer, such that there exists an open covering $\{U_1, \ldots, U_{C_E}\}$ of $B$ and a fiber bundle atlas $\varphi_i : E|_{U_i} \to U_i \times F$ whose transition functions take values in $K \subseteq \text{Diff}(F)$.

Remark 2. Note, that we do not assume the $U_i$ to be connected. Since every manifold $B$ can be covered by $\dim B + 1$ open sets each of which is a disjoint union of disks one gets $C_E \leq \dim B + 1$ for any bundle $E \to B$.

Suppose we have a bundle of Lie groups $E \to B$ with typical fiber $G$, i.e. the structure group is reduced to $\text{Aut}(G) \subseteq \text{Diff}(G)$. Then the space of smooth sections $\Gamma(E)$ is again a manifold, which becomes a Lie group under point wise multiplication.

Proposition 1. Suppose $\pi : E \to B$ is a bundle of Lie groups with typical fiber $G$. Then $N_{\Gamma(E)} \leq C_{E_{\text{Diff}(G)}}^{\text{Aut}(G)} N_G$.

The proposition will follow immediately from the following two lemmas.

Lemma 2. Let $E \to B$ be a bundle of Lie groups with typical fiber $G$ and suppose $\{V_1, \ldots, V_N\}$ is an open covering of $B$, such that $E|_{V_i}$ is trivial. Then there exist an open neighborhood $e \in V \subseteq \Gamma(E)$ and smooth mappings $F_i : V \to \Gamma_{V_i}(E)$ with $F_i(e) = e$ and $F_i(s) \cdots F_N(s) = s$, for all $s \in V$.

Lemma 3. Suppose $W$ is a finite dimensional manifold which need not be compact, $G$ a Lie group, $N_G < \infty$, $V \subseteq U \subseteq W$ open, such that $V \subseteq U$ and such that $U$ is compact. Then for every open neighborhood of $e \in U \subseteq C^\infty(V, W, G)$ there exist $h^1 = \exp(Y^1) \in U$, an open neighborhood $e \in V \subseteq C^\infty(V, W, G)$ and smooth mappings $S^1 : V \to C^\infty(V, W, G)$ with $S^1(e) = e$ and $[S^1(f), h^1] \cdots [S^{N_G}(f), h^{N_G}] = f$, for all $f \in V$.

Proof of Lemma 3. Choose bump functions $\lambda_i : B \to [0, 1]$ with $\text{supp} \lambda_i \subseteq V_i$ and such that $U_i := \{x \in B : \lambda_i(x) = 1\}$ still cover $B$. Using trivializations of $E|_{V_i}$ and
a chart of $G$ centered at $e$ which has a convex image in $\mathfrak{g}$ one defines a smooth map given by “multiplication with $\lambda_i$”

$$
\phi_i : \Gamma(E) \supseteq \mathcal{V} \to \Gamma_{\bar{V}}(E), \quad 1 \leq i \leq N,
$$

where $\mathcal{V}$ is an open neighborhood of the identical section. Obviously that map has the property, that $\phi_i(s) = s$ on $U_i$ and supp$(\phi_i(s)) \subseteq $ supp$(s)$. Now set $F_i(s) := \phi_i(s)$ and

$$
F_i(s) := \phi_i(F_{i-1}(s)^{-1} \cdots F_1(s)^{-1}s), \quad 1 \leq i \leq N.
$$

Shrinking $\mathcal{V}$ we may assume that everything is well defined. An easy inductive argument shows $F_1(s) \cdots F_i(s) = s$ on $U_1 \cup \cdots \cup U_i$, for all $s \in \mathcal{V}$ and all $1 \leq i \leq N$.

**Proof of Lemma [4].** Choose a bump function $\mu : W \to $ with supp$(\mu) \subseteq U$ and $\mu = 1$ on $V$. Let $\tilde{V}$, $\tilde{h}_i = \exp(\tilde{Y_i})$ and $\tilde{S}_i : \tilde{V} \to \tilde{U}$, $1 \leq i \leq N_G$, be the data we get from $N_G < \infty$ and a sufficiently small neighborhood of $e \in G$. Set $\mathcal{V} := \{f \in C^\infty_c(W,G) : f(\tilde{V}) \subseteq \tilde{V}\}$, $h^i(x) := \exp(\mu(x)\tilde{Y}_i)$ and $S^i := (\tilde{S}_i)_*$. 

**Proof of Proposition [5].** Choose open sets $V_i \subseteq \bar{V}_i \subseteq U_i \subseteq \bar{U}_i \subseteq W_i$, $1 \leq i \leq N_E$, such that $E|_{W_i}$ are trivial and such that $\{V_i\}$ is an open covering of $B$. Suppose we have given any open neighborhood $e \in U \subseteq \Gamma(E)$. For every $1 \leq i \leq N_E$ the second lemma provides, via trivializations of $E|_{W_i}$, $h^i \in U$, an open neighborhood $e \in \mathcal{V}_i \subseteq \Gamma_{\bar{V}}(E)$ and smooth mappings $S^j_i : V_i \to \Gamma(E)$, $1 \leq j \leq N_G$, with $S^j_i(e) = e$ and $[S^j_i(s), h^i] \cdots [S^{N_G}_i(s), h^{N_G}_i] = s$, for all $s \in V_i$. Let $e \in \mathcal{V} \subseteq \Gamma(E)$ be the open neighborhood from the first lemma and assume, that $F_i : \mathcal{V} \to V_i$. Then $S^j_i \circ F_i : \mathcal{V} \to \Gamma(E)$, $(S^j_i \circ F_i)(e) = e$ and

$$
\prod_{1 \leq i \leq N_E} \prod_{1 \leq j \leq N_G} [(S^j_i \circ F_i)(s), h^i] = s,
$$

for all $s \in \mathcal{V}$. 

**Example 4.** Suppose $M \to B$ is a finite dimensional principal bundle with perfect structure group $G$. Let Gau$(M)$ denote the group of gauge transformations. It is well known that Gau$(M) = \Gamma(E)$, where $E$ is the associated bundle of groups with typical fiber $G$. So Proposition [5] implies, that Gau$(M)$ is a smoothly perfect group, even gives concrete estimates, e.g. at least $N_{\text{Gau}(M)} \leq (\dim B + 1)(\dim G)$.

Similarly one can treat other examples, such as the group of automorphisms on a finite dimensional vector bundle preserving a fiber metric (fiber volume, fiber symplectic form), or the group of automorphisms on a finite dimensional bundle of groups (those which are fiber wise group isomorphisms), or the group of automorphisms on a finite dimensional bundle of Lie algebras.

5. Applications

Applications are given by a combination of the decomposition theorem and the fact that

$$
\text{Diff}(M, S) = \Gamma(E),
$$

where $M$ is a compact fiber bundle $S \hookrightarrow M \to B$, Diff$(M, S)$ denotes the fiber preserving diffeomorphisms of $M$ and $E$ denotes the associated bundle of Lie groups over $B$ with typical fiber Diff$(S)$. So Proposition [5] shows, that Diff$(M, S)$ is
smoothly perfect as soon as $\text{Diff}(S)$ is smoothly perfect. See also [Ryb95], where it is shown, that the group of leaf preserving diffeomorphisms on any foliated manifold is perfect. From Theorem 3 and Proposition 1 we immediately get the following

**Corollary 1.** Suppose $M$ is a closed manifold which admits $k$ fiber bundles $S_i \hookrightarrow M \xrightarrow{p_i} B_i$ such that the corresponding vertical distributions span $TM$. Then

$$N_{\text{Diff}(M)} \leq \sum_{i=1}^{k} C_{p_i} N_{\text{Diff}(S_i)}.$$  

Particularly $\text{Diff}(M)$ is smoothly perfect if all $\text{Diff}(S_i)$ are smoothly perfect.

Note, that if $M$ appears as a total space of one fiber bundle $S \hookrightarrow M \xrightarrow{p} B$ with $\dim(S) \geq 1$, one can always perturb $p$ and find finitely many fiber bundles $S \hookrightarrow M \xrightarrow{p_i} B$, whose vertical distributions span $TM$. Moreover we always have the estimate $C_p \leq \dim B + 1 \leq \dim M$.

**Example 5.** Since every odd dimensional sphere appears as the total space of an $S^1$-bundle via the Hopf fibration Example 3 implies, that $\text{Diff}(S^{2n+1})$ is smoothly perfect. For example one easily derives $N_{\text{Diff}(S^3)} \leq 18$.

**Example 6.** Since every compact Lie group $G$ has a torus as subgroup it appears as total space in an $S^1$-bundle and hence $\text{Diff}(G)$ is smoothly perfect. We even get the estimate $N_{\text{Diff}(G)} \leq 3(\dim G)^2$, for there are always $\dim G$ many $S^1$-bundle structures on $G$ which span $TG$.
