SYSTEMATIC REVIEW

What are the perspectives of speech pathologists, occupational therapists and physiotherapists on using telehealth videoconferencing for service delivery to children with developmental delays? A systematic review of the literature

Claire Grant BPhysio | Anne Jones PhD | Helen Land PhD

Abstract
Objective: To identify the attitudes and perspectives of speech pathologists, occupational therapists and physiotherapists on using telehealth videoconferencing for service delivery to children with developmental delays.
Design: Systematic Literature Review.
Method: An electronic search of databases Scopus, CINAHL, MEDLINE, PEDro, Speechbite, OTseeker and ScienceDirect was undertaken in October 2020. Articles were compared with eligibility criteria by 2 authors. All articles were appraised for quality and level of evidence.
Findings: Fourteen studies were deemed to be eligible. Results were synthesised using a narrative analysis. The themes identified were technology, self-efficacy, replacement of face-to-face services, time management, relationships, access and family-centred care. Each of these themes was seen as both a potential barrier and a facilitator when trying to provide services via telehealth.
Conclusions: The results in this review cannot be generalised due to small sampling size, low response rates, lack of maximum variation sampling and under-representation of occupational therapists and physiotherapists. Study design was either mixed-methods survey or interview or only survey or interview. Risk of bias in studies was high. Further research is required including comparison studies and cost-benefit analysis.

KEYWORDS
attitudes, occupational therapy, perspectives, physiotherapy, speech pathology, telepractice and children

1 | INTRODUCTION

1.1 | Developmental delay

Developmental delay occurs when children do not meet developmental milestones at the same rate as their age-matched peers. This could be for any reason, including a syndrome, dystrophy and birth trauma, or could be idiopathic. Allied health services in this group aim to facilitate social participation and inclusion. They work to improve required skills to facilitate a healthy progression into adulthood and facilitate engagement within the community by use of interactive sessions requiring visual assessment, interaction in the environment, speech and cognitive skills. These early-intervention services improve children’s health trajectory. However, children in rural and remote areas have reduced participation in these services compared with children in major cities and consequently have poorer health outcomes.

1.2 | Telehealth, a potential solution to rural service gaps

Allied health services in rural and remote locations are lacking compared with major cities; the number of allied health professionals per capita is significantly dropping with increased remoteness. The consequence of this scenario is poorer health outcomes in rural and remote areas and increased travel for both allied health professionals and patients. Some patients even go so far as to move permanently to a major city when requiring ongoing specialist services. Compounding the problem of reduced access to allied health is the issue of those few professionals available being unable to provide specialist services due to the lack of infrastructure, lack of specialist knowledge, funding priorities and staffing.

Telehealth is a potential solution to service gaps and inaccessibility to allied health care. Telehealth is the provision of health services over a geographical distance using telecommunications technology. Telehealth is an umbrella under which various technologies sit including emails, phone calls and videoconferencing and can be used for direct client services, training and administration. Videoconferencing is the most appropriate way to deliver real-time remote services to children with developmental delay due to the play-based nature of therapy and high visual and verbal communication needs in this group. Therefore, only telehealth videoconferencing is being considered in this review. Future references to telehealth indicate telehealth videoconferencing unless otherwise specified.

What is already known on this subject:
• Evidence supports the use of telehealth for allied health service delivery to children with disabilities; however, service gaps are still present in Australia
• Perspectives of patients are often reported; however, allied health professional perspectives are lacking
• Perspectives of clinicians are important to predict adoption of telehealth services

What this study adds:
• Speech pathologists, occupational therapists and physiotherapists perceive both barriers and facilitators to use of telehealth for service delivery to children
• Occupational therapists and physiotherapists are under-represented in the evidence
• The quality of evidence is insufficient to generalise to the population of interest

Growing evidence including systematic reviews supports telehealth to address service gaps in rural Australia. These reviews found that telehealth could provide reduced costs, reduced inconvenience, improved access and improved clinical outcomes to rural Australians. However, there are still barriers to widespread adoption of telehealth including lack of infrastructure, training and motivation and lack of research with high-quality methodologies.

1.3 | Predicting adoption of telehealth

Telehealth, just as it does for adult health services, offers a solution to this inequity in children’s health. The efficacy of telehealth as a delivery model for allied health services for children with disabilities was shown to be effective in a systematic review of randomised controlled studies. The children included in studies in this systematic review meet the definition of developmental delay. Occupational therapy and physiotherapy were poorly represented in the review. Wales et al found evidence supporting speech pathology delivered via telehealth in their systematic review but found that the evidence was generally of poor quality. Further studies are required to determine whether the use of telehealth is an effective way for speech pathologists, occupational therapists and physiotherapists to assess and treat children.

While the first step is to consider the efficacy of telehealth as a delivery method, efficacy becomes redundant
if stakeholders are not willing to use it. The technology acceptance model (TAM) proposed by Davis, discusses that perceived usefulness and perceived ease of use are predictors of whether a person will accept a technology. Adoption of telehealth services is dependent on clinician satisfaction, perception of usefulness and ease of use. Therefore, clinician perspectives are important, but they are rarely studied. Research on perspectives of telehealth primarily focuses on patient and family satisfaction; also an important predictor of success of telehealth.

It is insufficient that patients alone are accepting of telehealth; clinician perspectives should also be investigated. Informal conference discussions have shown that access to appropriate technology, organisational support and training were clinicians’ most perceived needs when considering adopting telehealth. Further rigorous research is required to consolidate these preliminary findings.

1.4 COVID-19

Until 2020, accessing rural populations was the focus of telehealth research in Australia. The COVID-19 pandemic prompted significant changes to our model of health care delivery. The Australian Government Department of Health introduced Medicare payments for telehealth services in 2020. Distance from health care services bears very little weight on this change. Instead, telehealth is being used to reduce exposure to infection for frontline workers. Camden and Silva reported that pre-COVID-19 only 4% of allied health professionals from 76 countries used telehealth in their work with children, whereas after the onset of COVID-19, 70% use telehealth. The influx of therapists using telehealth presents a unique opportunity to identify problems and solutions that can improve telehealth services to create better equity across allied health services in rural Australia post–COVID-19.

1.5 Knowledge gap

Numerous gaps are evident in the current research of telehealth in children with developmental delays and disabilities. There is a lack of randomised controlled studies and systematic reviews to support the efficacy of telehealth to deliver allied health services for this population. There is also a lack of understanding of what barriers and facilitators allied health professionals face when using telehealth to deliver services to children with developmental delays. This systematic review attempts to address the latter.

While allied health encompasses many health professionals, in this review the term refers only to physiotherapists, occupational therapists and speech pathologists. The reason for including these and excluding others is the similarity of these professions in the patient group, interventions, practice and collaboration. It was felt that they would be sufficiently similar to enable comparisons at the analysis stage.

1.5.1 Objective

To identify the attitudes and perspectives of allied health professionals (speech pathologists, occupational therapists and physiotherapists) towards using telehealth for service delivery to children with developmental delays.

2 METHOD

2.1 Design

This is a systematic literature review completed according to the Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) guidelines. The review protocol is registered with PROSPERO: CRD42020210996. The authors are not aware of any conflicts of interest.

2.2 Eligibility criteria

Inclusion criteria were as follows: (a) studies in English; (b) studies published from any year up until 2021; (c) studies including videoconferencing to deliver services to clients; (d) empirical, quantitative, qualitative, mixed-methods and original studies; (e) studies that included perspectives of allied health professionals who were of physiotherapy, occupational therapy or speech pathology disciplines; and (f) studies where the group receiving services were children with developmental delay.

Exclusion criteria were as follows: (a) studies not in English; (b) literature reviews; (c) pilot studies; (d) sought perspectives on telehealth that were not videoconferencing, for example online exercise programs and Web-based games; and (e) studies where interventions were provided only to adults.

2.3 Search strategy

An electronic search of databases Scopus, MEDLINE, ScienceDirect, PEDro, OTseeker, Speechbite and Cumulative Index to Nursing and Allied Health Literature (CINAHL) was conducted on 11 October 2020 and updated on 8 June 2021. The JCU library staff were consulted to identify key words and develop search strategies for each database. Searches varied due to the constraints of each database.
1. Medline and Scopus were searched using the following terms
("speech patholog*" OR "speech-language" AND "speech therap*" OR "speech and language" OR "physiotherap*" OR "physical therap*" OR "occupational therap*") AND (perspective* OR attitude*) AND (telehealth OR telepractice OR teletherapy OR telerehab* OR telemedicine) AND (child* OR paediatric OR pediatric)

2. ScienceDirect was searched using the following terms (perspective OR attitude) AND (telehealth OR telepractice OR teletherapy OR telerehabilitation OR telemedicine) AND ("allied health") AND child

3. CINAHL was automatically searched for synonyms of the key words used for the ScienceDirect search. MESH headings and subject headings were checked

4. PEDro was searched by selecting paediatrics as the sub-discipline and using the terms telepractice and telehealth in the abstract/title search bar. All search terms were matched with AND

5. Speechbite was searched by entering 'telehealth' and 'telemedicine' as keywords and selecting children in the age option

6. O’Seeker was searched by searching using the terms ‘telehealth’ OR ‘telemedicine’ AND ‘child*’

All databases were limited to English-only articles as none of the authors have a second language. To minimise the risk of missing relevant articles, a search was conducted of web pages and searching citations of included articles. Systematic and literature reviews from database searches that appeared relevant were hand-searched for articles meeting eligibility criteria.

2.4 Study selection

Articles were exported into Endnote and duplicates removed. The title and abstracts of the remaining articles were screened by Author 1 and Author 2 to find relevant full-text articles for further screening. Full-text articles were assessed against the eligibility criteria by Authors 1 and 2 independently and disagreements resolved by discussion with the eligibility criteria for reference. Study selection is outlined in Figure 1.

2.5 Methodological quality

Assessment of article quality was undertaken using the Crowe Critical Appraisal Tool (CCAT). This tool was chosen as it has been shown to be reliable for all research designs. The CCAT consists of eight categories that can be scored from 0 to 5, with a total score of 40 being the best possible score. The categories are the pre-amble, introduction, design, sampling, data collection, ethical matters, results and discussion. The CCAT has an intra-class correlation coefficient of 0.83 for consistency and 0.74 for total agreement. It has significant weak-to-moderate positive correlations (Kendall’s τ 0.33-0.55) when compared to other critical appraisal tools. Author 1 and Author 2 independently appraised the articles, and any differences between results were discussed to reach a consensus. The CCAT was also used to identify any bias in the articles so that this was considered in reviewing the findings (Table 3). Studies were compared with the evidence hierarchy presented by Ackley et al. This hierarchy was chosen as it provides a level for survey and qualitative designs.

2.6 Data extraction

Data extraction was conducted by Author 1. The data extracted from each study were organised into a table with categories for author, date of publication, location of study, study design, participants (including the number of participants and professions), patient groups, objectives and findings. This table was developed into the study characteristic table (Table 2). Data were sought and extracted on quantitative and qualitative items including perspectives of barriers and facilitators such as cost, time and feasibility.

2.7 Data synthesis

Narrative synthesis was chosen as the most appropriate way to analyse the diverse study designs and manage inconsistencies across outcomes measured. The narrative approach seeks to use storytelling to gather evidence of why a change should be made and to provide a trustworthy synthesis. Popay et al outlined 4 steps for a narrative synthesis. The first step, developing a theory of the intervention, was not appropriate as the studies primarily explored perceptions rather than an intervention. The second step, developing a preliminary synthesis of the findings, was followed during data extraction. The third step, exploring relationships in the data, was followed using a thematic analysis. To allow the story to emerge from the quantitative and qualitative data, the included articles were read and reread by Author 1 and Author 2. Organisation into themes was thought to be the best way to bring together the findings from each study. Quantitative data were transformed to qualitative to allow for coding and generation of themes. Author 1 leads the assignment of codes before meeting with Author 2 to discuss possible interpretations of the
codes before agreeing upon them. And finally, the fourth step, assessing the robustness of the synthesis, was followed by undertaking a thorough critical appraisal as previously discussed.

3 | RESULTS

3.1 | Study screening and selection

The initial electronic search yielded 608 studies (Table 1). Following the removal of duplicates, 598

| 2015                                     |                                                          | Sex not reported                                                                      |                                          |
| Edirippulige et al                       | Mixed-methods; qualitative semi-structured interviews and quantitative analysis of locations by geomapping. Queensland, Australia | 329 patients with cerebral palsy, 203 male, 126 female, mean age 9 y 13 clinicians including 4 occupational therapists, 2 physiotherapists and 2 speech pathologists. 92% had experience with telehealth | Children with cerebral palsy            |
| 2016                                     |                                                          | Age, sex and years of clinical experience not reported                                 |                                          |
| Ashburner, Vickerstaff, Beetge and Copley | Qualitative; semi-structured interviews Queensland, Australia                           | 4 mothers, 2 special education teachers, 2 classroom teachers, 2 occupational therapists, 2 speech pathologists. Clinical experience 6 wk to 20 y, all had experience with telehealth | Children with autism spectrum disorder, aged 3-7 y |
| 2016                                     |                                                          | Age and sex not reported                                                              |                                          |
| Objectives of the study | Data analysis | Results | Bias considered |
|-------------------------|---------------|---------|-----------------|
| 1. To explore factors influencing attitudes towards using ICT | Thematic content analysis | Barriers: | No |
|  |  | No direct interpersonal contact (lack of physical touch), lack of infrastructure, lack of training and support, lack of confidence, lack of time to implement telehealth |  |
| 2. To explore access and attitudes of NSW residents towards ICT | Descriptive statistics Comparison of survey results | Barriers: Should not replace face-to-face, need for training and support, lack of physical touch, personal finances |  |
| 3. To compare attitudes of NSW residents and SLPs towards ICT | Thematic analysis | Most SLPs reported they were not confident with videoconferencing |  |
| 1. To determine the types of telehealth technology used in speech and language services | Descriptive statistics Thematic analysis | Barriers: technology failures, lack of IT support, lack of telehealth infrastructure, inadequate training | No |
| 2. To determine the client populations telehealth is being used with clinically |  | Facilitators: Access, time efficiency for client and clinician, reduced costs, caseload management, client-focused |  |
| 3. To identify attitudes of SLPs towards telehealth |  | Descriptions: 50% had used videoconferencing |  |
| 1. What themes emerge from interviews about implementation of school-based telepractice? | Thematic analysis | Barriers: Technology barriers, inadequate training for SLPs and e-helpers, time to implement program, lack of physical touch, inappropriate for students with profound disabilities | Yes (selection) |
| 2. What are the knowledge, skills, attitudes and beliefs of SLPs towards telepractice in schools. |  | Facilitators: facilitates student learning, collaboration, access to speech pathologists, benefits families |  |
| 1. To determine SLP perceptions of telepractice in schools | Descriptive statistics | 6% had used telepractice, 86% had training before providing telepractice service, 70% thought training required, 14% agreed that rapport could be established via telepractice, and 30% interested in providing telepractice in schools | Yes (selection) |
| 1. To identify factors that contribute to positive clinician attitudes about telehealth | Thematic analysis | Positive attitudes towards therapeutic relationships with children, collaboration with teachers and parents, adequacy of technology and access to support and learning | No |
| 1. To understand methods of service delivery to patients with cerebral palsy | Descriptive statistics—qualitative responses and frequency reported | Geomapping: average 836km to Brisbane appointments and average 173km to outreach appointments | No |
| 2. To examine clinicians’ use and perceptions of telehealth |  | Barriers: disrupts clinician-client rapport, technology barriers, should not replace face-to-face as stand along treatment, impractical for certain assessments, privacy |  |
| 1. To understand what parents and service providers perceive as advantages and disadvantages of an early-intervention program delivered remotely | Thematic analysis | Barriers: Technical difficulties, should not replace face-to-face | Yes (response) |
|  |  | Facilitators: Reduces cost of time and travel for client and clinician, ups skills parents and providers, flexible, access for families, stakeholder collaboration |  |
articles remained. They were then screened by title and abstract with 558 being excluded due to irrelevance, and the remaining 40 articles were accessed in full text. Reasons for exclusion were not including videoconferencing, not discussing clinician perspectives, participants did not include speech pathologists, occupational therapists or physiotherapists or did not relate to children with developmental delays.

Fourteen of these articles met the eligibility criteria and were included in the review. The PRISMA\textsuperscript{30} flowchart used for study selection is shown below (Figure 1).
| Objectives of the study                                                                 | Data analysis                      | Results                                                                 | Bias considered |
|---------------------------------------------------------------------------------------|------------------------------------|------------------------------------------------------------------------|-----------------|
| 1. To explore parent and practitioner readiness for telehealth                         | Descriptive statistics and thematic analysis | Barriers: technology issues, poor confidence, inappropriate for children with autism, interferes with rapport  
Facilitators: improves travel time, children seen in familiar environment  
Descriptive: 57.9% of practitioners had used videoconferencing, 33.3% agreeable to using it for intervention, 73% believed time saving for family | No               |
| 2. To understand the perceived effects of rapport building on outcomes.                | Thematic analysis                  | Barriers: reliance on ′e-helpers′ such as parents and staff, selecting appropriate children for telehealth, lack of physical touch  
Facilitators: building rapport with families in remote areas | No               |
| 1. To identify feasibility, essential requirements and potential barriers in delivering therapy support to regional and remote participants on the autism spectrum via videoconferencing technology | Thematic analysis                  | Barriers: technology programs, poor relationships and lack of physical touch, self-efficacy, inferior relationships, clinical information missed, children would not be able to participate, privacy  
Facilitators: access, benefits families, technology barriers can be solved, telehealth supported by partnerships | Yes (generalisability) |
| 1. To examine allied health client, provider and community referrer perceptions of telehealth for the delivery of rural paediatric allied health services to facilitate adoption | Thematic analysis                  | Barriers: limits goals that require physical interaction ′lack of physical touch′, local staff changes, additional in-person services would help with rapport  
Facilitators: training builds confidence, adequate technology, collaboration, access to specialist services, similar to in-person sessions, fills the gap in regional services | No               |
| 1. To gather information on perspectives, perceived barriers and benefits of using telehealth for school-based occupational therapy | Descriptive statistics and thematic analysis | Barriers: logistics, lack of physical touch, privacy concerns,  
Facilitators: logistics (less travel), collaboration, better access to OTs, better access for homedbound students  
Descriptive: 28% likely to adopt telehealth, 14% unlikely, remaining preferred not to answer. 42% were interested in telehealth education, 42% were not and the remaining did not know | No               |
| 1. To establish speech and language pathologists′ perceptions of types of feeding services feasible via telehealth and current use of telepractice  
2. To explore barriers and facilitators to the delivery of paediatric feeding services via telepractice | Descriptive statistics and thematic analysis | Barriers: technology failure, safety and efficacy of feeding service, lack of training and experience, family perceptions  
Facilitators: reduced travel times and costs, benefits families (by reducing family burden of attending appointments), naturalistic environment, potential to increase services, access to clinical support  
Descriptive: 41% interested in using telehealth for feeding support, 20% had used telehealth for feeding support, and 4% felt no feeding services could be provided via telehealth | Yes (selection) |

### 3.2 Study characteristics

Five studies used a mixed-methods design. Hill and Miller, Raatz et al, and Rortvedt and Jacobs used a cross-sectional survey design with some open-ended questions for thematic analysis. Iacono et al used both cross-sectional survey and semi-structured interviews using descriptive statistics and thematic analysis, respectively, and Edirippulige et al used a qualitative interview and described locations using geomapping. The geomapping component has not been analysed in this systematic review.
| Study author and year | Preliminaries | Introduction | Design | Sampling | Data collection | Ethical matters | Results | Discussion | Total score and % |

Seven studies used a qualitative design employing semi-structured interviews. Two studies used cross-sectional survey design. All studies were level VI on the evidence hierarchy. Table 2 summarises study characteristics.

### 3.3 | Risk of bias

Bias was assessed using the CCAT and is presented in Table 3. There is a high risk that bias in data collection instruments was present in 12 of 14 studies as only Tucker pilot tested their survey and interviews prior to data collection. Akamoglu, Meadan, Pearson and Cummings acknowledged lack of validity and reliability of their survey as a limitation of their study. Bias in sampling was acknowledged by 3 studies. Campbell et al reported that they had no Indigenous respondents and that this did not reflect the population. While the above 3 studies considered sampling bias a risk, it appears that while it went unacknowledged, it was also a risk in the other studies as none of the included studies had a random sample. Raatz et al reported risk of selection bias as they considered it possible that their sample might have an interest in telehealth and therefore chose to respond to the survey. Akamoglu et al and Tucker required their participants to be experienced in telehealth; consequently, clinicians who deliberately avoided telehealth were not included. This might lead to a bias in under-reporting of barriers to the use of telehealth. Ashburner et al discussed that since the telehealth program was at no cost to the families, respondents might have been swayed to respond positively. Reporting bias was a risk in at least 4 studies that reported receiving funding from telehealth-motivated organisations. Studies that acknowledged bias generally scored higher using the CCAT than those that did not.

### 3.4 | Participant characteristics

Speech pathologists made up most participants (n = 412). Occupational therapists were less well represented than speech pathologists (n = 25), and physiotherapists had the smallest representation (n = 2). The studies by Dunkley et al and McAllister et al shared a participant pool. Age ranges and sexes of participants were not consistently reported. Studies that did report sex found that participants were more than 90 per cent female. Familiarity with telehealth was reported for some but not all studies. Reported familiarity ranged from 25 per cent by McAllister et al to 100 per cent by Akamoglu, Meadan, Pearson and Cummings. Clinical experience was not consistently reported.

### 3.5 | Patient demographics

Three studies reported a mix of paediatric and adult caseload. Five studies reported that children were mainly seen in a school setting. Three studies report that children had autism spectrum disorder (ASD). One study described the client group as children with cerebral palsy. The patient group for Raatz et al all had feeding difficulties. Finally, Campbell et al sought perceptions from therapists involved in a remote health scheme with services for both Indigenous and non-Indigenous children. All studies included some children requiring non-acute services for developmental delays.

### 3.6 | Synthesis of themes

Themes identified related either to allied health professionals or to families receiving the service. Allied health professional themes included technology, self-efficacy, face-to-face services, time management and relationships. Themes identified for families included access and family-centred care. Each of these themes was seen as both a potential barrier and a facilitator when trying to provide services via telehealth.

#### 3.6.1 | Allied health professionals

**Technology**

Technology failure or lack of technology infrastructure was identified in 7 studies as a barrier to the provision of services via telehealth, while one study identified appropriate access to support and technology as a facilitator to providing services via telehealth.

Technology failure was specified as Internet dropout by Iacono et al, a lack of telehealth infrastructure by McAllister et al and time-lag, computer crashing and screen freezing by Tucker. Dunkley et al reported that clinicians held the belief that families did not have the computer literacy or access to use telehealth. However, this belief was shown to be unsupported by family’s perceptions. One resident commented ‘like everyone else, we’ve got a fax and a computer and the internet [satellite connection] and all that’. Three studies reported that technology did not negatively impact the use of telehealth as clinicians found that issues could be worked through, that technology was not an issue and in one case that technology facilitated telehealth.

**Self-efficacy**

Participants in 6 studies identified lack of self-efficacy related to poor confidence or inadequate training as a barrier
to service delivery via telehealth. Adequate training, facilitating improved self-efficacy, was identified by 3 studies, resulting in easier use of telehealth as a service delivery method. Self-efficacy and training are closely linked; training improves self-efficacy in whichever skill is trained. Raatz et al reported that only 27% of its participants had received training in telehealth. Three studies included in the review identify support and training as facilitators to the use of telehealth. Johnsson et al reported that training built clinician confidence. Hill and Miller reported that 79% of respondents recommended further professional development and 66% recommended demonstrations by clinicians to enable skills in telehealth to be developed.

**Replacement for face-to-face services**

The inadequacy of telehealth to replace face-to-face therapy was reported as a barrier in 10 studies. Two reasons reported for this were the inappropriateness for certain client groups and the lack of physical touch available in a telehealth appointment. Three studies simply referred to unsuitability of telehealth as a replacement to face-to-face therapy.

While this theme was predominantly reported as a barrier, there were some positive perceptions. Two studies reported participant views that telehealth was similar to or even better than face-to-face services in some situations. Edirippulige et al reported views that telehealth was facilitative of pre- and post-operation planning for children with cerebral palsy and that telehealth was an effective adjunct to face-to-face services.

The 4 studies that found clinicians perceived that some client groups could not be provided services via telehealth specified those client groups as children with profound disabilities, those with ASD and other communication disorders and children with feeding difficulties. Concerns were that children with profound disabilities would not physically be able to use the videoconferencing technology and that children with communication difficulties could not engage through the screen. Raatz et al also reported concerns around efficacy and safety of telehealth for children with feeding difficulties.

**Time management**

Participants in 4 studies reported beliefs that telehealth negatively impacted time management as they did not have time to implement a telehealth service, while 4 studies reported beliefs that telehealth positively impacted time management by reducing clinician travel time.

Organising and scheduling telehealth was thought to be a burden on already heavy workloads due to the preparation of materials and technology. Clinicians also believed that without sufficient support by their organisation, time and costs would fall to the individual clinician. Two further studies reported perceptions that school-based appointments would have to be set up and supervised by a support person within the school and that this introduced logistical difficulties dependent on the priority the school placed on therapy.

**Relationships**

Participants in 4 studies reported that telehealth negatively impacted their therapeutic relationship with the child, while relationships and collaboration with parents and educators were reported to be improved in 7 studies. Allied health professionals perceived that they had an improved collaboration with teachers and improved relationships and upskilling of parents with parents when using telehealth. Another study reported perceptions that telehealth was more successful when it was supported by local providers and other stakeholders such as parents and teachers.

**Minor themes**

Other allied health professional themes were logistics, local staff changes and safety and efficacy of a feeding service acting as barriers to using telehealth for service delivery.

### 3.6.2 Families

**Access**

Reduced access for families was reported by one study, with allied health professionals believing families did not have sufficient technology or finances to access a telehealth service; however, this was not supported by family perceptions. Improved access for families was identified by allied health professionals in 7 studies, reporting reduced travel and time and reducing gaps in regional services as reasons.

**Family-centred care**

Three studies reported beliefs by allied health professionals that family-centred care would be negatively impacted by telehealth. Participants believed children would not participate in telehealth appointments and that family privacy would be compromised. While 2 studies reported participant beliefs that telehealth would improve privacy for families, 7 studies reported belief of improvements to family-centred care.

Telehealth was generally seen to be more convenient and less disruptive to child and family schedules than
attending a physical appointment. Reasons included facilitating academic learning as the appointment was easier to fit around the school day,\textsuperscript{40} improved carer engagement\textsuperscript{32,36} and was flexible for families.\textsuperscript{35} It was also reported that children and parents were more relaxed in their own familiar environment.\textsuperscript{31,32,35} Families felt they were supported to implement therapy strategies at home when therapy took place in the home context.\textsuperscript{35} Importantly, it was perceived that families for whom attending physical appointments was inconvenient due to complexity of disability, responsibilities for other children or parent work could still access interventions.\textsuperscript{32,35}

Reporting bias was limited by using a review protocol and the PRISMA guidelines.\textsuperscript{24} There is low certainty in the results as there is bias within each study, low quality of studies and high variation in populations and themes reported across each included study. This should be considered when reading recommendations and the conclusion.

4 | DISCUSSION

4.1 | Key findings

The objective of this review was to identify the attitudes of allied health professionals (speech pathologists, occupational therapists and physiotherapists) towards using telehealth for service delivery to children with developmental delays. The identified attitudes and perspectives can be summarised into 7 main themes. Clinician themes are technology, self-efficacy, replacement of face-face services, time management and relationships. Family themes are access and family-centred care. These themes give an insight into the potential of telehealth to manage service gaps in rural areas past the necessities of the COVID-19 pandemic.

4.2 | Limitations

Limitations of this systematic review method were restricting to peer-reviewed databases and English-language articles. Grey searching was used to control this. There is a risk that not all relevant search terms were used; however, this risk was controlled by using a librarian to assist with the search strategy. Limitations identified in the included studies include 2 studies sharing data sets.\textsuperscript{39,41} Population characteristics were not consistently reported throughout the studies; however, speech pathologists were included more frequently than occupational therapists and physiotherapists so findings cannot be generalised across disciplines. Patient group characteristics were inconsistently described; thus, conclusions on which patient populations are suitable for telehealth are unable to be drawn. Study design was a further limitation with only one study using a comparison group,\textsuperscript{38} and this study was appraised to be of poor quality.\textsuperscript{35} No study was greater than VI on the evidence hierarchy.\textsuperscript{27}

4.3 | Implications for clinical practice

Potential solutions to be applied to clinical practice arise in the themes of technology, self-efficacy, time management and access. In the theme of technology, studies reporting positive perceptions of technology were published in 2019.\textsuperscript{36,38} The studies reporting technology as a barrier varied from 2008 to 2020 in year of publication.\textsuperscript{13,31,32,35,36,39,40} While certainly no conclusions can be drawn from this, it is encouraging that recent studies have some positive perceptions of telehealth and report beliefs that technological issues can we worked through.\textsuperscript{38} A potential solution in clinical practice is prioritising personal technological equipment upgrades (eg laptop with suitable processing) and readily available technology support to reduce technological difficulties.\textsuperscript{11}

Self-efficacy associated with lack of training was frequently reported throughout the review.\textsuperscript{13,31,36,39-41} Lack of self-efficacy could be rectified by providing training and support prior to and during the implementation of telehealth programs.\textsuperscript{43} Indeed, the participants in the review recognised this need themselves.\textsuperscript{9,13,38} Allied health professionals in rural areas have been shown to be time poor\textsuperscript{10}; therefore, the initial time investment in telehealth training to reduce time cost in future should be impressed upon clinicians.

The theme of time management brought forward some surprising perceptions; given the significant time cost of travel for rural health appointments,\textsuperscript{9} negative perceptions towards time management were unexpected. There were concerns around logistics of setting up a telehealth appointment and time wasted on managing technological difficulties.\textsuperscript{33,34} Potential solutions are adequate training and technology, along with contingency plans for when unavoidable technological failures occur. In addition, improved relationships with stakeholder groups might help with time spent organising appointments around opposing schedules.\textsuperscript{37} The onus should be placed on the organisation implementing telehealth to ensure policies and procedures are in place to support efficient use of telehealth.\textsuperscript{11}

While access has been considered a ‘family’ theme in this review, it also has some potential to increase buy-in from allied health professionals. Reduced costs due to telehealth have been reported in other areas of health provision (in this case, oncology\textsuperscript{44}) due to avoidance of
clinician travel costs. This research is yet to be emulated in the children’s physiotherapy field. Organisational cost savings could redirect funding to allied health staffing in rural areas, thereby improving access to allied health services for families and reduced staffing pressures for organisations.\textsuperscript{11} Should telehealth be shown to be cost-effective, telehealth has the potential to improve access across rural settings.\textsuperscript{11}

### 4.4 Implications for future research

When considering telehealth as a replacement to face-to-face services, there was a lack of specificity in reporting around the population telehealth was used with. Edirippulige et al\textsuperscript{9} did specify that speech pathologists felt telehealth should not replace face-to-face therapy for children with cerebral palsy, while occupational therapists believed it was similar to face-to-face therapy. Physiotherapists in this study believed telehealth was useful for pre- and post-operation planning for children with cerebral palsy.\textsuperscript{9} It is possible that therapies historically requiring less physical touch, for example post-surgical follow-up,\textsuperscript{9} would be seen as more acceptable via telehealth than a high-risk therapy like a swallowing assessment.\textsuperscript{32}

However, as reasons were not clearly identified it is only possible to speculate. In future, detailed data pertaining to the intervention and patient group might provide clarity.

When considering relationships, clinicians were unsure how to build relationships with children over the screen.\textsuperscript{9,31,33,36} Further studies should explore building rapport with children via telehealth. In addition, training programs should include this to increase clinician confidence with building rapport via telehealth.

Access was largely seen as a positive with perceptions that there was reduced burden of travel and travel-related costs for families.\textsuperscript{13,33,35,36,38-40} Travel for health care by both providers and families is a major financial and environmental issue in rural Australia.\textsuperscript{44} One study in rural Queensland reported mean travel times for each family for a child’s outreach visit were 5 hours and 46 minutes for each visit to and from a central hub.\textsuperscript{9} Perceptions of reduced travel might also increase buy-in from allied health professionals. Reduced costs associated with reduced clinician travel have been reported in other areas of health provision (in this case, oncology).\textsuperscript{45} This research is yet to be emulated in the children’s physiotherapy field. Organisational cost savings could redirect funding to allied health staffing in rural areas, thereby improving access to allied health services for families and reduced staffing pressures for organisations.\textsuperscript{11} Should telehealth be shown to be cost-effective, telehealth has the potential to improve access across rural settings as organisations see financial benefit in servicing those areas.\textsuperscript{11}

### 5 Conclusions

This systematic review investigated the perspectives of allied health professionals on using telehealth to deliver interventions to children with developmental delays. Synthesis of this literature identified that there are both facilitators and barriers to adoption of telehealth for allied health service delivery in children with developmental delay. Facilitators included improved access to services, family-centred care and collaboration with stakeholders. Barriers identified were the belief that telehealth cannot replace face-to-face therapy, technology failure, lack of self-efficacy, lack of time to implement telehealth service and interference with therapeutic relationships.

Evidence quality was limited by study design with only studies with low-quality evidence identified and high risk of bias present within studies. The low-quality evidence means that the results should be treated with caution. The generalisability of findings is limited due to sampling methods, small sample sizes and low response rates. Occupational therapists and physiotherapists were underrepresented in the populations included in this review.

This review highlights that many barriers are perceived, but solutions and workarounds to these barriers can also be identified. These findings need to be corroborated by higher quality studies. Further studies should consider the cost versus benefits of allied health telehealth services for children with developmental delays and represent the views of occupational therapists and physiotherapists.

### Acknowledgements

Claire Grant works as a physiotherapist with children with developmental delay for a private company. She undertook the systematic review as part of a masters by research at the James Cook University. Anne Jones and Helen Land are both employees of the James Cook University.
