Graphical Abstract

Zinc supplementation can help maintain learning and memory function in rodents. In this study, we hypothesized that zinc supplementation could antagonize the neurotoxicity induced by aluminum in rats. Animals were fed a diet containing different doses of zinc (50, 100, 200 mg/kg) for 9 weeks, and orally administered aluminum chloride (300 mg/kg daily) from the third week for 7 consecutive weeks. Open-field behavioral test results showed that the number of rearings in the group given the 100 mg/kg zinc supplement was significantly increased compared with the group given the 50 mg/kg zinc supplement. Malondialdehyde content in the cerebrum was significantly decreased, while dopamine and 5-hydroxytryptamine levels were increased in the groups given the diet supplemented with 100 and 200 mg/kg zinc, compared with the group given the diet supplemented with 50 mg/kg zinc. The acetylcholinesterase activity in the cerebrum was significantly decreased in the group given the 100 mg/kg zinc supplement. Hematoxylin-eosin staining revealed evident pathological damage in the hippocampus of rats in the group given the diet supplemented with 50 mg/kg zinc, but the damage was attenuated in the groups given the diet supplemented with 100 and 200 mg/kg zinc. Our findings suggest that zinc is a potential neuroprotective agent against aluminum-induced neurotoxicity in rats, and the optimal dosages are 100 and 200 mg/kg.

INTRODUCTION

Aluminum is the third most common element in the earth’s crust and is ubiquitous in the environment\textsuperscript{[1]-[4]}. Despite the abundant presence and wide exposure to this metal, its biological and biochemical functions still remain unclear\textsuperscript{[6]-[7]}. The wide presence and use of aluminum has stimulated considerable interest in the toxicity of this metal. Daily sources of aluminum intake include water, cooking utensils, food additives, and drugs such as antacids and deodorants. AlCl\textsubscript{3}·6H\textsubscript{2}O was chosen in this study because of its widespread use as a coagulant in water treatment.

Aluminum has been associated with several neurodegenerative diseases, such as Alzheimer’s disease, Parkinson’s disease, dialysis encephalopathy, amyotrophic lateral sclerosis and Guam-Parkinson’s dementia\textsuperscript{[8]-[11]}. The mechanisms underlying aluminum neurotoxicity are unclear, although it appears that the metal contributes to oxidative damage\textsuperscript{[12]-[15]}, disruption of calcium homeostasis\textsuperscript{[16]-[18]} and impairment of intracellular signal transduction pathways\textsuperscript{[19]-[21]}. Thus the mechanisms of aluminum neurotoxicity are complex, but likely affect neurotransmission, learning and memory function, and related behavior.

Zinc, an essential trace element for growth and development, is distributed throughout the body, and concentrations are especially high in the limbic system, including the hippocampus, hypothalamus and amygdala\textsuperscript{[22]-[23]}. Zinc plays extremely critical roles in normal growth and development, cellular homeostasis, and numerous biochemical functions, including protein synthesis and nucleic acid metabolism. Furthermore, zinc is involved in immunological, neurological, endocrine, and sensory functions, as well as gene expression\textsuperscript{[24]-[28]}. The crucial role of zinc in neurogenesis, neuronal migration, synaptogenesis and neurotransmission make it closely related to learning and memory function. Liu and coworkers studied the effect of different concentrations of dietary zinc on learning and memory function, brain somatostatin levels, and zinc and calcium concentrations in Wistar rats. Their results suggested that a diet containing 100–200 mg/kg zinc is adequate for maintaining learning and memory function in rats\textsuperscript{[29]}.

In our previous study\textsuperscript{[30]}, we found that acetylcholinesterase activity was decreased and lipid peroxidation was enhanced in the cerebrum of male Wistar rats after treatment with aluminum chloride at a dose of 300 mg/kg daily for 7 weeks. In this study, we aimed to evaluate the effect of zinc supplementation on aluminum-induced neurotoxicity.

RESULTS

Quantitative analysis of experimental animals

Thirty healthy adult Wistar rats were equally and randomly divided into three groups: 50, 100 and 200 mg/kg zinc groups. Each group received a diet containing the respective concentration of zinc for 9 weeks. From the third week, rats in each group were intragastrically injected with 300 mg/kg aluminum trichloride for 7 consecutive weeks. Eight rats in each group were selected for the determination of zinc concentration and biochemical indexes in brain tissue, while the remaining two rats were used for pathological observations.

No rats exhibited signs of infection or died during the experimentation. All 30 rats were included in the final analysis, without dropout.

Effect of zinc supplementation on open-field activity in aluminum-exposed rats

On day 60 of zinc supplementation, the open-field test was carried out to evaluate the motility and spontaneous exploration of rats. Data for horizontal activity and rearings in the open field are shown in Table 1.
Effect of zinc supplementation on learning and memory function in aluminum-exposed rats

On day 61 of zinc supplementation, learning and memory function, an important aspect of cognitive function in rats, was assessed with the passive avoidance task. The retention latency in the groups given the 50, 100 and 200 mg/kg zinc supplementation was 275.80 ± 76.53, 243.80 ± 118.50 and 274.20 ± 81.59 seconds, respectively. There were no significant differences among the groups.

Effect of zinc supplementation on aluminum and zinc concentrations in the cerebral of aluminum-exposed rats

On day 63 of zinc supplementation, the aluminum and zinc concentrations in the cerebrum of animals were determined (Table 2). Among the groups, the concentrations of aluminum and zinc showed no significant differences.

Effect of zinc supplementation on malondialdehyde content and superoxide dismutase and acetylcholinesterase activities in the cerebral of aluminum-exposed rats

On day 63 of zinc supplementation, the malondialdehyde content, superoxide dismutase and acetylcholinesterase activities were determined. The effects of aluminum and zinc treatment on several biochemical markers in the cerebrum are shown in Table 3. The malondialdehyde content in the cerebrum was significantly increased in the groups treated with 100 and 200 mg/kg zinc compared with the group treated with 50 mg/kg zinc (P < 0.05). The acetylcholinesterase activities in cerebrum were significantly decreased in rats fed the diet containing 100 mg/kg zinc (P < 0.05). There was no significant difference in superoxide dismutase activity in the cerebrum among the three groups.

Effect of zinc supplementation on dopamine and 5-hydroxytryptamine levels in the cerebral of aluminum-exposed rats

On day 63 of zinc supplementation, the dopamine and 5-hydroxytryptamine concentrations in the cerebrum of rats were assayed (Table 4). Compared with the group given the diet supplemented with 50 mg/kg zinc, dopamine and 5-hydroxytryptamine levels were increased in the groups treated with 100 and 200 mg/kg zinc, but there was no significant difference among the three groups.
hippocampus was examined under the light microscope (Figure 1). Pyknosis is the irreversible condensation of chromatin in the nucleus of a cell undergoing programmed cell death or apoptosis. Pyknotic nuclei and prominent perineuronal spaces were observed in the hippocampus of rats in the group fed the diet supplemented with 50 mg/kg zinc. In comparison, pyramidal cells in the hippocampus displayed a relatively normal appearance in the groups treated with 100 and 200 mg/kg zinc.

Table 4  Effect of zinc supplementation on dopamine and 5-hydroxytryptamine levels in the cerebrum of aluminum-exposed rats

| Group                  | Dopamine (μg/g) | 5-Hydroxytryptamine (μg/g) |
|------------------------|----------------|---------------------------|
| Supplemented with 50 mg/kg zinc | 1 771.4± 635.6       | 1 035.1±244.1            |
| 100 mg/kg zinc         | 1 765.6±850.1      | 1 000.1±409.3            |
| 200 mg/kg zinc         | 2 658.4±807.2      | 1 570.7±547.4            |

Data are expressed as mean ± SD (n = 8), and differences between groups were compared using one-way analysis of variance with Scheffé post-hoc test.

DISCUSSION

There are numerous investigations of aluminum neurotoxicity in experimental animals. However, the neurotoxic effects of aluminum in experimental animals have been controversial because they are dependent on the route of administration [31-33], type of aluminum salt [34-36], species of animal [37-39], dose of treatment [40-42] and time of exposure [39-44]. In most studies, the duration of aluminum exposure ranges from 8 weeks to 6 months.

The present study was performed to investigate the protective effects of zinc on aluminum-induced neurotoxicity in the cerebrum of male Wistar rats. Administration of zinc protected against histopathological changes in aluminum-exposed rats, thereby demonstrating its neuroprotective action.

In the present study, short-term memory was not significantly altered among the different groups. This result is similar to previously reported findings [45-46]. However, in many other studies, short-term memory was significantly altered after aluminum exposure [47-48]. The discrepancy in these findings may result from differences in methodology, including variations in dose, timing and route of aluminum administration.

Our previous study showed that aluminum exposure induces a significant reduction in locomotor activity in rats (data not shown). These results confirmed the findings of others using the open-field test [49-51]. In the present study, the impairment in locomotor activity induced by aluminum was less severe in the groups treated with 100 and 200 mg/kg zinc, compared with the group given the diet supplemented with 50 mg/kg zinc.

In this study, damage to lipids was assessed by measuring malondialdehyde content. Malondialdehyde is the
end-product of lipid peroxidation\(^{[52]}\). Thus, malondialdehyde levels can be used to estimate the degree of lipid peroxidation and the levels of tissue oxygen radicals. Exposure to AlCl\(_3\) at 100 mg/kg per day for 8 weeks may lead to increased levels of lipid peroxidation\(^{[12]}\). Exposure to AlCl\(_3\) at 50 mg/kg per day for 3 months also results in enhancement of lipid peroxidation\(^{[53]}\). In the present study, malondialdehyde levels in the cerebrum were significantly lower in the groups treated with 100 and 200 mg/kg zinc compared with the group given the diet supplemented with 50 mg/kg zinc. This indicates that zinc may alleviate oxidative damage following aluminum exposure.

Acetylcholinesterase has received wide attention in the study of aluminum neurotoxicity\(^{[47, 54]}\). Acetylcholinesterase is a cholinergic marker enzyme\(^{[54]}\) and aluminum has been suggested to act as a cholinotoxin\(^{[55]}\). It was observed that administration of aluminum causes a significant increase in acetylcholinesterase activity in the cerebral cortex of rats\(^{[53]}\). Bhalla et al\(^{[47]}\) observed a decrease in acetylcholinesterase activity after aluminum exposure in both the cerebrum and cerebellum. Similar observations were made by Ravi et al\(^{[56]}\). Furthermore, Kumar\(^{[57]}\) explored the biphasic effect of aluminum on acetylcholinesterase activity in brain regions in vivo. We postulate that the disparity in findings may be due to differences in dose, duration and route of aluminum exposure in the various studies. The present study reveals that co-administration of 100 mg/kg zinc to aluminum-exposed animals is able to reduce the aluminum-induced increase in acetylcholinesterase activity in the cerebrum.

Dopamine is secreted from neurons that originate in the substantia nigra. A decrease in dopamine levels is observed after aluminum exposure in the cerebrum, cerebellum\(^{[47]}\) and hypothalamus\(^{[58]}\). A significant decrease in 5-hydroxytryptamine levels is also observed after prolonged aluminum exposure in both the cerebrum and cerebellum\(^{[47]}\), and there are region-specific variations in the levels of 5-hydroxytryptamine\(^{[47, 59]}\). 5-Hydroxytryptamine is a neurotransmitter synthesized from tryptophan via the intermediate 5-hydroxytryptophane.

In the present study, the dopamine and 5-hydroxytryptamine levels were improved (i.e., higher) in the groups treated with 100 and 200 mg/kg zinc compared with the group treated with 50 mg/kg zinc. By microscopic observation, increased neuronal apoptosis was seen after aluminum treatment. This likely affects neurotransmission, and hence, learning and memory processes. Zinc supplementation may reduce neuronal apoptosis.

In conclusion, the present study indicates that zinc supplementation prevents aluminum-induced neurotoxicity in the cerebrum. By inhibiting oxidative stress and histopathological changes, zinc supplementation helped normalize the activity of cholinergic marker enzymes affected by aluminum. Thus, the present study shows that zinc can be used as a neuroprotectant. Zinc helps to protect against neuronal cell death and helps to maintain normal neurotransmission and behavioral functions during aluminum toxicity. Further studies are required to elucidate the mechanisms by which zinc exerts its neuroprotective effects.

**MATERIALS AND METHODS**

**Design**

A randomized, controlled animal experiment.

**Time and setting**

The experiment was performed at the laboratory in the Department of Nutrition, Institute of Health & Environmental Medicine, Academy of Military Medical Sciences, Tianjin, China, from September 2008 to January 2011.

**Materials**

A total of 30 healthy male Wistar rats weighing 217.6 ± 7.6 g were purchased from the Experimental Animal Center of the Military Medical Sciences, China (license No. SCXK-2007-004). All experimental protocols were in strict accordance with the Guidance Suggestions for the Care and Use of Laboratory Animals, issued by the Ministry of Science and Technology of China\(^{[60]}\).

Prior to the experiments, animals were allowed to acclimatize for 7 days. Thirty male Wistar rats were housed in polypropylene cages, under pathogen-free conditions, with a 12-hour light/dark cycle, and temperature was maintained at 22 ± 2°C. Animals were given feed and deionized water *ad libitum*.

All animal studies conformed to the Guide for the Care and Use of Laboratory Animals published by the US National Institutes of Health.

**Methods**

**Zinc supplementation**

Aluminum was administered by gavage. Rats were ran-
domly assigned to three groups, each group consisting of ten animals. Male Wistar rats were exposed orally to aluminum chloride, whereas zinc was given in the form of ZnSO₄·7H₂O (Tianjin Shentai, Tianjin, China) through diet. In all groups, rats received aluminum chloride (300 mg/kg per day; Tianjin Standard Science and Technology, Tianjin, China). Animals were administered different doses of zinc in the diet, namely 50, 100 or 200 mg/kg zinc[29]. The diets were formulated as described previously by the American Institute of Nutrition AIN-93[61]. The treatments were given over a period of 9 weeks, and all rats received aluminum chloride as of the fifteenth day. At the end of the treatment schedules, the following behavioral studies were conducted.

**Behavioral tests**

Open-field test for motility and spontaneous exploration: The open-field test was carried out on day 60 to evaluate the motility and spontaneous exploration of rats. An open-field apparatus was utilized, consisting of a black plastic 1 m × 1 m arena divided into 20 cm × 20 cm squares. The open field was enclosed with 50-cm-high side walls. Each animal was placed in the middle of the field, and activity was counted during 3-minute sessions. Both horizontal (square crossings) and vertical (rearings) activities were measured. The number of square crossings and rearings was recorded.

Passive avoidance test for short-term memory: Passive avoidance performance was observed on day 61 to assess short-term memory as reported previously[80]. Briefly, the test was conducted for 2 days, including one acquisition trial and one testing trial, during the same time of day. In the acquisition trial, a rat was put into the bright compartment, and it received an electric foot shock (40 V) for 3 seconds through the stainless steel grid floor if it entered the dark compartment. Then, the rat would escape back to the bright compartment.

After 24 hours, the testing trial was conducted, identical to the acquisition trial, except that no electric shock was delivered if the rat entered the dark compartment. The time the rat took to enter the dark compartment was recorded and tabulated as escape latency (seconds). Rats were allowed to stay in the bright compartment for 300 seconds in the testing trials.

**Biochemical analysis**

Tissue homogenate preparation: On day 63, rats were lightly anesthetized and killed by decapitation after the behavioral tests were completed. Brains were removed and weighed individually. Thereafter, cerebrums were dissected out for biochemical analysis. Homogenates of the cerebrum were prepared in 0.9% NaCl solution. The homogenate was centrifuged at 3 000 r/min, 4°C, for 15 minutes. The clear supernatant was used for the estimation of malondialdehyde content, superoxide dismutase activity and acetylcholinesterase activity.

Malondialdehyde content determination: Malondialdehyde, a reliable marker of lipid peroxidation, was determined with thiobarbituric acid according to the manufacturer’s instructions (Nanjing Jiansheng Bioengineering Institute, Nanjing, Jiangsu Province, China) on day 63. Supernatants (0.1 mL) were transferred to a testing tube. A standard solution (0.1 mL) was added to each standard testing tube, and distilled water (0.1 mL) was added to another blank testing tube. A 2 mL aliquot of thiobarbituric acid was added into each of these two tubes, which were agitated several times, and then incubated at 95°C for 1 hour. Then, each specimen was cooled to room temperature and centrifuged at 3 000 r/min for 10 minutes. Finally, the supernatant in each tube was subjected to colorimetric assay at 532 nm. Total protein content in samples was analyzed using a bicinchoninic acid protein assay kit (Shanghai Sangon Biotech, Shanghai, China). The results were expressed in nmol MDA per milligram of tissue homogenate (nmol/mg protein).

Superoxide dismutase activity determination: Superoxide dismutase is a key enzyme in the dismutation of superoxide radicals, resulting from cellular oxidative metabolism, into hydrogen peroxide. On day 63, superoxide dismutase activity was determined using an assay kit (Nanjing Jiansheng Bioengineering Institute) and expressed as units per microgram of total protein (U/mg). Total protein content in samples was assessed using a bicinchoninic acid protein assay kit (Shanghai Sangon Biotech).

Acetylcholinesterase measurement: On day 63, acetylcholinesterase activity was determined using an assay kit (Nanjing Jiansheng Bioengineering Institute). The substrate used was acetylthiocholine. The mercaptan formed was reacted with DTNB, which splits into two products, one of which is 5-thio-2-nitrobenzoate, which absorbs at 412 nm. The results were expressed as units per microgram of total protein (U/mg).

Estimation of neurotransmitter levels: At 63 days after zinc supplementation, dopamine and 5-hydroxytryptamine concentrations in the cerebrum were assayed using a Waters 600 HPLC system (Waters,
USA) with electrochemical detection. Frozen cerebrums were homogenized in 1 mL 0.1 mol/L HCl with an internal standard added. Homogenates were centrifuged at 12,000 r/min, 4°C, for 10 minutes in a refrigerated centrifuge. Dihydroxybenzylamine was used as an internal standard. The results were expressed as micrograms per gram (μg/g).

**Estimation of aluminum and zinc concentrations**

At 63 days after zinc supplementation, the aluminum and zinc concentrations in the cerebrum were estimated from each animal following wet acid digestion with concentrated nitric acid\(^{[83-70]}\).

Digested samples were brought to a constant volume and determination of tissue aluminum concentration was performed with an Elan DRCII ICP-MS (Perkin-Elmer, Norwalk, USA). The tissue zinc concentrations were measured directly by flame atomic absorption spectrophotometry (Hitachi, Tokyo, Japan).

**Histopathological examination**

At 63 days after zinc supplementation, animals were sacrificed at the end of the experiment. Brain specimens were dissected out and immediately fixed in 10% formalin. Tissues were processed for preparation of paraffin blocks (paraffin method).

Sections were cut using a rotator microtome, mounted on slides, stained with hematoxylin and eosin and examined by light microscopy (Leica, Wetzlar, Germany).

**Statistical analysis**

Statistical analysis was performed using one-way analysis of variance with Scheffé post-hoc test, using SPSS 11.5 software (SPSS, Chicago, IL, USA). Data are expressed as mean ± SD. All P values were two-tailed, and differences were considered significant at P < 0.05.

**Research background**:
The biological functions of zinc in neurogenesis, neuronal migration, synapse formation and neurotransmission are closely associated with learning and memory function.

**Research frontiers**: No existing study has explored the protective effect of zinc supplementation against aluminum-induced neurotoxicity. This study aims to investigate the mechanisms underlying the neuroprotective effect of zinc supplementation against brain dysfunction induced by aluminum exposure in rats.

**Clinical significance**: The experimental findings further our understanding of the mechanisms underlying the neuroprotective effect of zinc supplementation against brain dysfunction in aluminum-exposed rats. The findings should help in developing strategies for preventing and treating neurodegenerative diseases caused by aluminum exposure.

**Academic terminology**: Lipid peroxidation—oxidation by hydrogen peroxide or superoxide of unsaturated fatty acids to produce peroxides non-enzymatically.

**Peer review**: This study examined the effect of different doses of zinc on behavioral function, cerebral cortex biochemical indices and pathological abnormalities in rats exposed to aluminum, with the aim of understanding the role of zinc in the prevention and treatment of chronic aluminum exposure-induced neurotoxicity. Further study, in which a control group has received no zinc supplement, is urgently needed.
