Combination of Theoretical and Experimental Insights into the Oxygenated Fuel Poly(oxymethylene) Dibutyl Ether from \( n \)-Butanol and Paraformaldehyde

Gaojun An, Yangfeng Xia,* Zhenzhen Xue, Hongyan Shang, Sainan Cui, and Changbo Lu*

ABSTRACT: Oxygenated fuel has the function of self-supplying oxygen during the combustion process, which can greatly improve emission performance and reduce diesel fuel soot production. In this paper, a novel oxygenated fuel poly(oxymethylene) dibutyl ether (PODBE\(_n\)) is designed and synthesized through experiments in combination with density functional theory (DFT) calculation. The experimental results show that PODBE\(_n\) has the advantages of high cetane number (73.6), moderate density (868 kg/m\(^3\)), and low condensation point (\(-72 \, ^\circ\)C). According to the DFT calculation results, the molecular (PODBE\(_n\)) polarity index of different polymerization degrees is similar to the value of diesel and has good mutual solubility with diesel. Moreover, the mechanism of the entire path of synthesis is calculated at the M06-2X/6-311G(d,p) level of theory. The energetic profile reveals that the rate-determining step is the nucleophilic addition step with the highest barrier energy (TS1 = 21.59 kcal/mol). This work provides a feasible method to synthesize high-performance oxygenated fuel PODBE\(_n\) using NKC-9 ion-exchange resins.

1. INTRODUCTION

It is well known that oxygenated fuels such as methanol, dimethyl ether (DME), and poly(oxymethylene) DME (PODE\(_n\)) can significantly reduce nitrogen oxides (NO\(_x\)) and particulate matter (PM) emissions when used as diesel fuel additives.\(^1\)–\(^5\) These oxygenated compounds have attracted much attention due to their clean energy properties. However, the physicochemical features of methanol and DME are considerably different from that of ordinary diesel fuels (such as high vapor pressure, low viscosity, and so on), requiring changes to the diesel engine infrastructure.\(^6\)–\(^10\) Compared with methanol or DME, PODE\(_n\) has physicochemical properties similar to that of standard diesel. When used as a substitute for diesel fuel or a mixed fuel with diesel, it will not have a significant impact on the performance of the diesel engine.\(^11,12\) Furthermore, various pieces of literature have demonstrated that PODE\(_n\) may effectively suppress NO\(_x\) and PM emissions due to its high oxygen content (45–50\%).\(^13\)–\(^17\)

As a result, PODE\(_n\) is viewed as a viable oxygenated fuel for solving diesel pollution.

PODE\(_n\) (molecular formula: CH\(_3\)-O-(CH\(_2\O\))\(_n\)-CH\(_3\), where \( n \) is the degree of polymerization of the methoxy group) is a kind of polyether-oxidized fuel whose structure consists of a repeating unit \(-\text{O-CH}_2\text{-}\) and two ending groups (methoxy \(-\text{O-CH}_3\) and methyl \(\text{CH}_3\)).\(^5\)–\(^8\)\(^18\)–\(^20\)

Among PODE\(_n\) with different chain lengths \((n = 1–8)\), medium-chain PODE\(_{3–5}\) are considered to be more preferable for diesel additives due to their high oxygen content, moderate boiling range, and vapor pressure compared with diesel.\(^11,12,21–24\)

When the chain length of PODE\(_n\) is short \((n < 2)\), its flash point is too low to meet the safety standards, and when the chain length is long \((n > 5)\), solid precipitation may form when mixed with conventional fuels and block the fuel system. Although PODE\(_{3–5}\) have aroused widespread interest as diesel fuel additives, the industrial application of PODE\(_n\) oxyfuel has not been carried out so far. The critical problem limiting PODE\(_n\)’s large-scale research and application is its high density \((\geq 1.02 \, \text{g/mL})\) and molecular polarity, which result in poor solubility with diesel at low temperatures.\(^25\)–\(^27\)

Hence, it is very necessary and meaningful to develop a novel polyether-oxidized fuel with density and molecular polarity similar to that of diesel.

The manufacture of oxygen fuel poly(oxymethylene) dibutyl ether (PODBE\(_n\)) molecule formula: C\(_4\)H\(_9\)-O-(CH\(_2\O\))\(_n\)-C\(_4\)H\(_9\), where \( n \) is the degree of polymerization of the methoxy group) from \( n \)-butanol and paraformaldehyde (PF) as reactants is described in this study. The main catalytic reaction...
parameters such as molar ratio, temperature, and reaction time have been evaluated in an autoclave reactor, with NKC-9 ion-exchange resin as a catalyst. In addition, the molecular polarity of PODBE was examined using the molecular polarity index (MPI).\textsuperscript{28,29} Electrostatic potential (ESP) was used to examine the charge distribution on the molecule surface.\textsuperscript{30} The transition states (TSs) were calculated at the M06-2X/6-311G(d,p) level of theory. The weak interactions between different atoms were analyzed by noncovalent interactions (NCIs).\textsuperscript{31}

2. RESULTS AND DISCUSSION

2.1. Synthesis of PODBE\textsubscript{n} (n = 1–6). 2.1.1. Influence of the Molar Ratio of n-Butanol and PF. The molar ratio of the reactants is a key factor affecting the distribution and yield of different PODBE\textsubscript{n} polymers. The effect of n-butanol and PF molar ratios (1:0.6, 1:0.8, 1:1.0, 1:1.2, and 1:1.4) on the yield and product distribution of PODBE\textsubscript{1−6} was investigated using NKC-9 resin as a catalyst. Figure 1a shows that the distribution of the PODBE\textsubscript{n} (n = 1−4) polymer changes significantly as the molar ratio of n-butanol and PF increases. With the increase of PF molar ratio, the yield of PODBE\textsubscript{1} gradually decreased, while that of PODBE\textsubscript{n} (n = 2−4) gradually increased, indicating that the increase of PF molar ratio was beneficial to the formation of products with higher degree of polymerization. When the degree of polymerization “n” up to 5 or 6, the yield of PODBE\textsubscript{n} (n = 5−6) was small (0.42%) and hardly changed with the PF molar ratio.

According to Figure 1b, as the PF molar ratio increases from 1:0.6 to 1:1.0, the overall yield of PODBE\textsubscript{1−6} steadily increases (from 68 to 74%). When the PF molar ratio is increased to 1:1.2, the overall yield of PODBE\textsubscript{1−6} nearly doubles (73%), indicating that the PF reaction concentration is saturated at this level. Therefore, further experiments were carried out under the condition that the molar ratio of n-butanol and PF was 1:1.0.

2.1.2. Influence of Reaction Temperature. Figure 2 illustrates the investigation of the effect of reaction temperature (from 70 to 110 °C) on the distribution and yield of PODBE\textsubscript{1−6}. The yield of PODBE\textsubscript{1} gradually falls as the reaction temperature increases, but the yield of PODBE\textsubscript{2} rises and subsequently decreases, reaching a maximum value (17%) at 100 °C, and the yield of PODBE\textsubscript{5−6} does not change considerably with the reaction temperature. With the temperature increase from 70 to 100 °C, the total yield of PODBE\textsubscript{1−6} increases from 67 to 74%. When the temperature rises to 110 °C, the overall yield of PODBE\textsubscript{1−6} falls to 72%. The internal structure of the reactor may be damaged as a result of the maximum reaction temperature of 110 °C of the NKC-9 resin collapsing, thereby reducing its catalytic efficiency. The results show that the appropriate temperature is 100 °C.

2.1.3. Influence of Reaction Time. The effect of reaction time (2, 4, 6, 8, and 10 h) on the yield and degree of polymerization of the product PODBE\textsubscript{1−6} was investigated (Figure 3). In terms of polymer distribution, as the reaction time grows, the yield of PODBE\textsubscript{1} decreases while the yield of PODBE\textsubscript{2} increases, showing that the degree of polymerization of the product increases with reaction time. As the time increases from 2 to 6 h, the yield of PODBE\textsubscript{1−6} increases from 68 to 74%. When the reaction time exceeds 6 h, the yield of PODBE\textsubscript{1−6} hardly changes, indicating that the reaction has

![Figure 1. Influence of molar ratio (n-butanol/PF) on the distribution and yield of PODBE\textsubscript{1−6}; (a) distribution of PODBE\textsubscript{n} (n = 1−6) and (b) yield of PODBE\textsubscript{1−6}. Reaction conditions: NKC-9 (2 wt %); temperature, 100 °C; and time, 6 h.](https://pubs.acs.org/doi/10.1021/acsomega.1c06452)

![Figure 2. Influence of reaction temperature on the distribution and yield of PODBE\textsubscript{1−6}; degree of polymerization T is the total yield of PODBE\textsubscript{1−6}. Reaction conditions: NKC-9 (2 wt %); the molar ratio of n-butanol and PF was 1:1.0; time, 6 h.](https://pubs.acs.org/doi/10.1021/acsomega.1c06452)
reached equilibrium at this time. Hence, 6 h was chosen as the optimized reaction time.

2.2. Physical and Chemical Performance Analysis. To further assess PODBE\textsubscript{1−6}’s effectiveness as a diesel-blending component, the physical and chemical properties of PODBE\textsubscript{1−6}, PODE\textsubscript{3−6}, and diesel were examined (Table 1).

Table 1. Physical and Chemical Properties of PODBE\textsubscript{1−6}, PODE\textsubscript{3−6}, and Diesel

| entry | cetane number | PODE\textsubscript{3−5} \textsuperscript{a} | PODE\textsubscript{1−6} \textsuperscript{b} | diesel \textsuperscript{c} |
|-------|---------------|-----------------|-----------------|-----------------|
| 1     | 73.6          | 55.2            | 50.9            |                 |
| 2     | 31.6          | 24.7            | 43.1            |                 |
| 3     | 868           | 1046            | 807             |                 |

The cetane number is the most important metric for measuring the diesel combustion performance. Table 1 shows that the cetane number is listed in the following order: PODBE\textsubscript{1−6} (73.6) > PODE\textsubscript{3−5} (55.2) > diesel (50.9) (entry 1), indicating that PODBE\textsubscript{1−6} as a diesel-blending component can increase the diesel combustion performance significantly. Compared with the net heating value of PODE\textsubscript{3−5} (24.7 MJ/kg), PODBE\textsubscript{1−6} has a significant improvement (31.6 MJ/kg), which is beneficial to the fuel dynamic performance (entry 2). The density is listed in the order PODE\textsubscript{3−5} (1046 kg/m\textsuperscript{3}) > PODBE\textsubscript{1−6} (868 kg/m\textsuperscript{3}) > diesel (807 kg/m\textsuperscript{3}), showing that PODBE\textsubscript{1−6} is more compatible with diesel and is better suited as a diesel-blending component (entry 3). The condensation point of PODBE\textsubscript{1−6} (−72 °C) is much lower than that of diesel (−40 °C) and PODE\textsubscript{3−5} (−52 °C). This phenomenon shows that PODBE\textsubscript{1−6} has excellent low-temperature performance and can be applied in high-altitude and low-temperature areas (entry 6). In addition, PODBE\textsubscript{1−6} and PODE\textsubscript{1−6} have comparable boiling range and flash point values, matching the diesel requirement (entries 4 and 5).

Above all, PODBE\textsubscript{n} (n = 1−6) are more suitable than PODE\textsubscript{n} (n = 3−5) as diesel-blending components, and when mixed with diesel, they can significantly improve the combustion performance and low-temperature performance of diesel.

2.3. MPI Analysis. The ESP and MPI studies of the simulation oil (n-heptane + toluene + cyclohexane),\textsuperscript{32} PODE\textsubscript{1−6}, and PODBE\textsubscript{1−6} are shown in Figure 4 to compare the polarity of diesel, PODE\textsubscript{1−6}, and PODBE\textsubscript{1−6} intuitively. The ESP distribution of n-heptane and cyclohexane in the simulation diesel is consistent (the molecular surface ESP distribution maps are entirely white), resulting in low molecular polarity (Figure 4a,b; MPI = 2.74 and 2.33 kcal/mol). The surface of the toluene molecule presents a negative ESP at the position of the benzene ring (the ESP distribution graph is blue), while the hydrogen atom presents a positive ESP (the ESP distribution graph is red), resulting in greater molecular polarity (Figure 4c; MPI = 7.90 kcal/mol).

ESP and MPI investigations of PODE\textsubscript{1−6} (Figure 4d−i) demonstrate that the oxygen atoms in the PODE\textsubscript{1−6} molecules display negative ESP, while the alkyl group exhibits positive ESP, resulting in an unequal distribution of the molecular surface. The MPI value shows an increasing trend as the degree of molecular polymerization increases, and the order follows: PODE\textsubscript{1} (13.55 kcal/mol) < PODE\textsubscript{2} (15.71 kcal/mol) < PODE\textsubscript{3} (17.12 kcal/mol) < PODE\textsubscript{4} (18.09 kcal/mol) < PODE\textsubscript{5} (18.82 kcal/mol) < PODE\textsubscript{6} (19.38 kcal/mol).

When compared to PODE\textsubscript{1−6}, the MPI values of PODBE\textsubscript{1−6} are all lower, indicating that the value of PODBE\textsubscript{1−6} is closer to the molecular polarity of simulated diesel (Figure 4j−o). According to the rule of the likes dissolve each other, the compatibility of PODBE\textsubscript{1−6} with diesel is better than that of PODE\textsubscript{1−6} and is more suitable as a diesel-blending component.

2.4. Reaction Mechanism Analysis. 2.4.1. Entire Reaction Path. Figure 5 shows a potential chemical pathway for the synthesis of PODBE\textsubscript{1−6} from n-butanol and PF. The reaction can be observed to be separated into two processes: (1) acetal reaction process; (2) chain growth process (Figure 5a). In the acetal reaction process, the condensation reaction between FA and n-butanol occurred to form the hemiacetal intermediate BuOCH\textsubscript{2}OH. Due to its unstable nature, the intermediate hemiacetal readily interacts with n-butanol to generate PODBE\textsubscript{1}. During the chain growth process, PODBE\textsubscript{1} was protonated by an acidic NKC-9 catalyst to generate the monomer FA to yield BuOCH\textsubscript{2}OH.32

When the temperature exceeds 72 °C, the reaction process consists of three main steps. The first step is a nucleophilic addition of FA to n-butanol, which results in the formation of the hemiacetal intermediate BuOCH\textsubscript{2}OH. The TS1 connects reactant A and intermediate

Figure 3. Influence of reaction time on the distribution and yield of PODBE\textsubscript{1−6}. Degree of polymerization T is the total yield of PODBE\textsubscript{1−6}. Reaction conditions: NKC-9 (2 wt %); molar ratio of n-butanol and PF was 1:1.0; temperature, 100 °C.

Figure 4. ASP and MPI of PODBE\textsubscript{1−6}, PODE\textsubscript{1−6}, and diesel. Each molecule’s ESP and MPI (Figures 4a,c,f,i) were depicted by the molecular surface. The ESP distribution of each molecule’s surface was shown in Figure 4d,e,g,h. The MPI value shows an increasing trend as the degree of molecular polymerization increases, and the order follows: PODE\textsubscript{1} < PODE\textsubscript{2} < PODE\textsubscript{3} < PODE\textsubscript{4} < PODE\textsubscript{5} < PODE\textsubscript{6}.

The cyclic structure of the PODBE\textsubscript{1−6} molecule causes the ESP distribution to be more complex than other molecules, thus resulting in high MPI values (Figure 4d,e,g,h).
Figure 4. MPI analysis of diesel (model oil), PODE$_{1-6}$ and PODBE$_{1-6}$: (a) n-heptane; (b) toluene; (c) cyclohexane; (d) PODE$_1$; (e) PODE$_2$; (f) PODE$_3$; (g) PODE$_4$; (h) PODE$_5$; (i) PODE$_6$; (j) PODBE$_1$; (k) PODBE$_2$; (l) PODBE$_3$; (m) PODBE$_4$; (n) PODBE$_5$ and (o) PODBE$_6$.

Figure 6. Energy studies of the acetal reaction process are as follows: (a) Gibbs free-energy barrier analysis, (b) IRC calculation, (c) energy analysis of the dehydration process, and (d) energy analysis of nucleophilic addition. The dashed lines represent the distances between two atoms in the structural development. The distance unit is Å.

Figure 7. Optimized geometries of TS structures for the chain growth process: (a) TS1, (b) TS2, (c) TS3, (d) TS4, (e) TS5, and (f) TS6.
B with a free barrier energy of 21.59 kcal/mol in this step. Further, the O14 atom of n-butanol attacks the C15 atom of FA, resulting in the formation of a new chemical bond between O14 and C15 (Figure 6a). The intrinsic reaction coordinate (IRC) analysis of step 1 proved the correctness of the transition-state TS1 structure (Figure 6b). The second step includes a dehydration process and the formation of carbocation BuOCH2+\(\textsuperscript{+}\). According to the energy scanning analysis, as the distance between O18 and C15 atoms rises (from 1.264 to 2.264), the total energy of the system decreases. This occurrence suggests that this stage is a spontaneous process with no TS structure (Figure 6c). The third step is the nucleophilic reaction between BuOCH2+\(\textsuperscript{+}\) and n-butanol to form BuOCH2OH\(\textsuperscript{+}\)Bu and then across deprotonation to prepare PODBE\(\textsuperscript{n}\). The energy scan analysis of this step shows that when the distance between C15 and O31 gradually closes (from 2.509 to 1.504 Å), the total energy of the system gradually decreases, indicating that this step is also a spontaneous process (Figure 6d).

2.4.3. Chain Growth Process Analysis. To further analyze the synthesis mechanism of PODBE\(\textsuperscript{1−6}\), the main TS structures forming the target product PODBE\(\textsuperscript{n}\) (\(n = 1−6\)) are listed in Figure 7. From Figure 5b, it is observed that the chain growth process mainly includes nucleophilic substitution reaction and nucleophilic reaction. As previously stated, the nucleophilic addition reaction between carbocation and n-butanol was a spontaneous reaction with no TS structures (Figure 6d). As a result, a complete TS analysis of the nucleophilic substitution process is critical for understanding the mechanism of PODBE\(\textsuperscript{n}\) synthesis.

From Figure 7, it is observed that the value of free Gibbs barrier energy of TS1 (21.59 kcal/mol) is the highest among all TS structures. This investigation has demonstrated that the acetal reaction process’s nucleophilic addition phase is the rate-determining step in the synthesis of PODBE\(\textsuperscript{1−6}\). The free Gibbs barrier energies for TS2−TS6 are as follows: TS2 (5.01 kcal/mol) \(\approx\) TS3 (5.01 kcal/mol) > TS4 (5.01 kcal/mol), TS5 (5.01 kcal/mol), and TS6 (5.01 kcal/mol). According to the reaction mechanism of the chain growth process, the products from PODBE\(\textsuperscript{1}\) to PODBE\(\textsuperscript{6}\) are sequentially generated in the order of the degree of polymerization \(n\) from small to large (Figure 5b), so the contents of PODBE\(\textsuperscript{1−6}\) follow the sequence \(n = 1 > n = 2 > n = 3 > n = 4 > n = 5 > n = 6\). Further, this sequence is consistent with the experimental results, verifying the reliability of the DFT calculation results.

Moreover, the TS structures are also analyzed by NCI, and the corresponding NCI maps are shown in Figure 8. In TS1 a blue circle isosurface is observed between O14 and C15, which means the O14 atom of n-butanol has a strong interaction with C15 of FA, thus resulting in the nucleophilic addition of n-butanol and FA (Figure 8a). The O atom of FA has a strong contact with the C atom of the carbocation in TS2−TS6, which facilitates the nucleophilic substitution process between FA and carbocation. The strong hydrogen bond between them is demonstrated by the blue circle isosurface distribution (Figure 8b−f).

3. CONCLUSIONS
In this research, a novel oxygen-containing fuel (POD\(\textsuperscript{BE}_{\textsuperscript{1−6}}\)) was formulated to overcome the limitations of PODE, such as...
its high polarity, poor compatibility with diesel at low temperatures, and low heating value. The reaction parameters, physicochemical properties, and reaction mechanism of PODBe were systematically investigated through experiments combined with DFT calculations. It was found that, under optimal conditions, the yield of PODBe can reach 74%. The MPI tests of PODBe, PODBe, and diesel (model oil) revealed that the polarity of PODBe is closer to that of diesel than PODBe, implying that it is theoretically more compatible with diesel. Furthermore, the physicochemical properties of PODBe such as cetane number, heating value, density, and low-temperature performance have obvious advantages compared with that of PODBe and diesel. DFT was used to calculate the mechanism of the complete path at the level of M06-2X/6-311G(d,p). The reaction consists of two processes, and the nucleophilic addition step with the highest Gibbs barrier energy (TS1 = 21.59 kcal/mol) is the rate-determining step.

4. EXPERIMENTAL SECTION

4.1. Materials. n-Butanol (99%), KBr (≥99.5%), and DMSO-d6 (99.9%) were purchased from Aladdin Reagent (Shanghai, China). PF (≥96%) was purchased from Sinopharm Chemical Reagent (Beijing, China). NKC-9 acidic ion-exchange resin (H+ type) was purchased from Tianjin Nankai Resin Technology Co., Ltd. (Tianjin, China). All reagents and chemicals were used directly without further purification and treatment.

4.2. Synthesis of PODBe. n-Butanol, PF, and NKC-9 (2 wt %) were added in a 0.5 L stirred autoclave reactor with a magnetic stirrer. The air within the reactor was changed three times with N2 before the reaction began. The reaction conditions were optimized to be 1:0.6 to 1:1.2 n-butanol/HCHO mole ratio, 2–10 h reaction time, and 1.0 MPa reaction pressure. After the reaction, the autoclave was cooled to room temperature, the pressure in the autoclave was filtered to remove the catalyst NKC-9. To obtain pure products of PODBe, PODBe and PODBe, the filtrate was decarboxylated with a decarboxylation agent and distilled at 90 mbar. Unfortunately, the reaction mixture contains inadequate PODBe, PODBe, and PODBe, and their boiling temperatures are too high. We cannot get pure PODBe, PODBe, and PODBe, so only their GC–MS characterization data are available.

4.2.1. PODBe. A colorless liquid. IR (KBr): ν = 2957, 2930, 2966, 1740, 1369, 1181, 1112, 1043, 1002, 933, 818, 736 cm⁻¹. ¹H NMR (600 MHz, d⁶-DMSO): δ = 4.58 (s, 2H, CH₂), 3.45 (t, J = 6.5 Hz, 4H, CH₂), 1.49 (dd, J = 14.7, 6.7 Hz, 4H, CH₉), 1.34 (dd, J = 15.0, 7.4 Hz, 4H, CH₂), 0.89 ppm (t, J = 7.4 Hz, 6H, CH₉). ¹³C NMR (151 MHz, d⁶-DMSO): δ = 71.7 (O–C=O), 67.9 (C–O), 31.8 (CH₂), 19.4 (CH₉), 14.1 ppm (CH₃).

4.2.2. PODBe. A colorless liquid. IR (KBr): ν = 2962, 2935, 2862, 1456, 1383, 1195, 1080, 993, 938, 832, 736 cm⁻¹. ¹H NMR (600 MHz, d⁶-DMSO): δ = 4.68 (s, 4H, CH₂), 3.48 (t, J = 6.6 Hz, 4H, CH₂), 1.49 (dt, J = 14.5, 6.6 Hz, 4H, CH₂), 1.33 (dd, J = 15.0, 7.5 Hz, 4H, CH₂), 0.88 ppm (t, J = 7.4 Hz, 6H, CH₉). ¹³C NMR (151 MHz, d⁶-DMSO): δ = 91.78 (O–C=O), 67.71 (C–O), 31.72 (CH₂), 19.29 (CH₉), 14.09 ppm (CH₃).

4.2.3. PODBe. A colorless liquid. IR (KBr): ν = 2967, 2935, 2870, 1461, 1383, 1204, 1116, 970, 919, 823, 740 cm⁻¹. ¹H NMR (600 MHz, d⁶-DMSO): δ = 4.77 (s, 3H, CH₉), 3.48 (t, J = 6.6 Hz, 4H, CH₂), 1.53–1.43 (m, 4H, CH₂), 1.32 (dd, J = 15.0, 7.5 Hz, 4H, CH₂), 0.88 ppm (t, J = 7.4 Hz, 6H, CH₉). ¹³C NMR (151 MHz, d⁶-DMSO): δ = 92.21 (O–C=O), 88.32 (O–C–O), 67.79 (C–O), 31.69 (CH₂), 19.27 (CH₉), 14.08 ppm (CH₃).

4.3. Analysis Methods. The infrared (IR) spectra were obtained using an infrared spectrometer (Nicolet iS50, America), with KBr salt flakes serving as the test background. NMR spectra comprise ¹H NMR and ¹³C NMR, which use a NMR spectrometer (Bruker AVANCE 600, Switzerland). The ¹H NMR working frequency is 600 MHz, the ¹³C NMR working frequency is 151 MHz, and Me₄Si is used as an internal standard. The cetane number of oxygenated fuels is measured by a cetane number machine (Waukesha, America). The flash point of oxygenated fuels is measured by a flash point machine (PM-93, England). The condensation point test adopts a freezing point meter (DSA-70X, Canada) for measurement. The net heating value is measured by an automatic bomb calorimeter (6300, America). The density of the petroleum products tester is used to determine the density (DSY-412, China). The reactants and products are determined using a gas chromatograph (Agilent 7820A, America), with the selected HP-5 capillary column as the chromatographic column (30 m × 0.32 mm × 0.25 µm, America), and an FID detector. The column temperature programming conditions are as follows: initial temperature, 50 °C for 5 min; heating rate, 15 °C/min; and final temperature, 250 °C for 10 min. The detector temperature is 300 °C.

4.4. Calculated Details. All calculations were performed by Gaussian 09 software. The geometries of PODBe, PODBe, and diesel fuel surrogates were optimized at the M06-2X/6-311G(d,p) level of theory. There are no negative eigenvalues in any of the optimized structures. A linear transit approach was used to search the TS structures, which revealed only one negative eigenvalue at an uncertain saddle point. Furthermore, IRC computations verified that all of the discovered TSs connected the reactants and products. The ESP analysis is based on the M06-2X/6-311G(d,p) level of theory. The ESP distribution on the surface of PODBe molecules with different degrees of polymerization is also analyzed. The ESP map’s blue–white–red colors represent the low, medium, and positive ESP levels in these regions, respectively. The polarity of different PODBe molecules is quantitatively analyzed by comparing the values of different MPI (eq 1).

\[ MPI = \frac{1}{A} \int S V(r) dS \]  

where A and V(r) refer to the specific surface area and ESP value of point r in space, respectively, and dS refers to the integration of the molecular surface. The higher value of MPI indicates the strong molecular polarity of the compound.
