Local root numbers of elliptic curves over dyadic fields

Naoki Imai

Abstract

We consider an elliptic curve over a dyadic field with additive, potentially good reduction. We study the finite Galois extension of the dyadic field generated by the three-torsion points of the elliptic curve. As an application, we give a formula to calculate the local root number of the elliptic curve over the dyadic field.

Introduction

Let $K$ be a non-archimedean local field with residue field $k$. Let $E$ be an elliptic curve over $K$. If $E$ has potentially multiplicative reduction, then $E$ has split multiplicative reduction over a quadratic extension of $K$ (cf. Proposition 1.1). On the other hand, if $E$ has potentially good reduction, then we need a bigger extension to get good reduction in general.

We assume that $E$ has potentially good reduction. Let $p$ be the characteristic of $k$. We consider a finite Galois extension $L$ of $K$, which is obtained by adding the coordinates of the $(p + 1)$-torsion points of $E$. Then $E$ has good reduction over $L$ (cf. Proposition 1.2). The inertia subgroup of Gal$(L/K)$ is studied by Kraus in [Kra90] if the characteristic of $K$ is zero. We will extend the results to positive characteristic cases. Actually, if $p \geq 3$, the proof in [Kra90] works without change. Hence, we focus on the case where $p = 2$. If $p = 2$, then $K$ is called a dyadic field. Further, we study the Galois group itself not only the inertia subgroup.

The local root numbers of elliptic curves are studied by many people. If the characteristic of $K$ is zero, they are calculated by Rohrlich in [Roh96] except the case where $p = 2, 3$ and the elliptic curves have additive potentially good reduction. Halberstadt gives a table of local root numbers of elliptic curves in [Hal98] if $K$ is $\mathbb{Q}_2$ or $\mathbb{Q}_3$. Kobayashi calculates them in [Kob02] in the case where $p \geq 3$ and $E$ has potentially good reduction. Using a result of [Kra90], Dokchitser-Dokchitser shows a formula calculating the local root numbers of elliptic curves over 2-adic fields in [DD08]. In this paper, we extend the formula of Dokchitser-Dokchitser to the positive characteristic cases using the study of the Galois extension $L$ over $K$. See Theorem 4.6 for details of the formula.

In Section 1 we recall basic facts on elliptic curves over non-archimedean local fields. In Section 3 we study the Galois group Gal$(L/K)$ and give a classification
in Theorem 3.8. In Section 4, we show a formula calculating the root numbers of elliptic curves over dyadic fields. The proof of the formula is rather independent of the classification in Theorem 3.8.

Acknowledgment
The author is grateful to a referee for careful reading and a number of suggestions for improvements.

Notation
In this paper, we use the following notation. Let \( K \) be a non-archimedean local field with a residue field \( k \) of characteristic \( p \). We write \( \mathcal{O}_K \) for the ring of integers in \( K \). Let \( v \) be the normalized valuation of \( K \). We take an algebraic closure \( K^{ac} \) of \( K \). For any finite extension \( F \) of \( K \), let \( W_F \) denote the Weil group of \( F \).

1 Elliptic curve
Let \( E \) be an elliptic curve over \( K \). Then \( E \) has a minimal Weierstrass equation

\[
y^2 + a_1 xy + a_3 y = x^3 + a_2 x^2 + a_4 x + a_6
\]

with \( a_1, \ldots, a_4, a_6 \in \mathcal{O}_K \). We put

\[
\begin{align*}
b_2 &= a_1^2 + 4a_2, \\
b_4 &= a_1a_3 + 2a_4, \\
b_6 &= a_3^2 + 4a_6, \\
b_8 &= a_2^2a_6 - a_1a_3a_4 + 4a_2a_6 + a_2a_3^2 - a_4^2, \\
c_4 &= b_2^2 - 24b_4, \\
c_6 &= -b_2^3 + 36b_2b_4 - 216b_6, \\
\Delta &= -b_2^2b_8 - 8b_4^3 - 27b_6^2 + 9b_2b_4b_6, \\
j &= c_4^3/\Delta.
\end{align*}
\]

Then we have

\[
\begin{align*}
4b_8 &= b_2b_6 - b_4^2, \\
1728\Delta &= c_4^3 - c_6^2.
\end{align*}
\]

as in \([\text{Tat75, (1.3)}]\). Then \( E \) has potentially good reduction if and only if \( v(j) \geq 0 \) (cf. \([\text{Sil09, VII. Proposition 5.5}])

The following fact is due to Tate:

**Proposition 1.1** (cf. \([\text{Sil09, Appendix C. Theorem 14.1.(d)}]\)). If \( v(j) < 0 \), then \( E \) has split multiplicative reduction over a quadratic extension of \( K \).
For a finite extension $F$ over $K$ inside $K^{ac}$ and a set $S$ of points of $E(K^{ac})$, let $F(S)$ be the extension of $F$ inside $K^{ac}$ obtained by adding the $x$ and $y$ coordinates of the points of $S$ to $F$. For such an $F$ and a point $P$ of $E$, we simply write $F(P)$ for $F(\{P\})$. For a positive integer $m$, let $E[m]$ denote the kernel of the $m$-multiplication map on $E(K^{ac})$.

**Proposition 1.2.** Let $m \geq 3$ be an integer that is prime to $p$. If $v(j) \geq 0$, then $E$ has good reduction over $K(E[m])$.

**Proof.** This follows from [ST68, Corollary 3 to Theorem 2] and [Sil09, VII. Proposition 5.4.(a)]. □

## 2 Group theory

For a natural number $n$, we write $\mathfrak{S}_n$ for the symmetric group of degree $n$, $C_n$ for the cyclic group of order $n$, $D_{2n}$ for the dihedral group of order $2n$, $SD_{2n}$ for the semidihedral group of order $2n$. We write $Q_8$ for the quaternion group. Here we recall an elementary fact on group theory.

**Proposition 2.1.** The natural action of $GL_2(\mathbb{F}_3)$ on $\mathbb{P}^1(\mathbb{F}_3)$ defines a surjection $GL_2(\mathbb{F}_3) \to \mathfrak{S}_4$. Furthermore, $2$-$2$ partitions of the $4$ point set $\{1, 2, 3, 4\}$ defines a surjection $\mathfrak{S}_4 \to \mathfrak{S}_3 = D_6$. For a subgroup of $GL_2(\mathbb{F}_3)$, we consider the image and kernel of the restriction of $GL_2(\mathbb{F}_3) \to D_6$ to the subgroup. Then a list of the isomorphism classes of subgroups of $GL_2(\mathbb{F}_3)$ is given by the following table:

| Ker | Im | C_1 | C_2 | C_3 | D_6 |
|-----|----|-----|-----|-----|-----|
| C_1 | C_1 | C_2 | C_3 | D_6 | @ |
| C_2 | C_2 | C_2 x C_2 | C_6 | D_{12} |
| C_4 | C_4 | C_8, D_8 | - | - |
| Q_8 | Q_8 | SD_{16} | SL_2(\mathbb{F}_3) | GL_2(\mathbb{F}_3) |

Further, the images under the surjection $GL_2(\mathbb{F}_3) \to \mathfrak{S}_4$ of subgroups that are isomorphic to $C_8$ and $D_8$ are isomorphic to $C_4$ and $C_2 \times C_2$ respectively.

**Proof.** We treat only distinction between $C_8$, $D_8$ and $Q_8$. It is well-known that the kernel of the surjection $GL_2(\mathbb{F}_3) \to D_6$ is the unique subgroup that is isomorphic to $Q_8$. The subgroups that are isomorphic to $C_8$ are conjugate to the subgroup generated by

$$
\begin{pmatrix}
0 & 1 \\
1 & 1 \\
\end{pmatrix}
$$

Hence, their images in $\mathfrak{S}_4$ are isomorphic to $C_4$. On the other hand, the subgroups that are isomorphic to $D_8$ are conjugate to the subgroup generated by

$$
\begin{pmatrix}
1 & 0 \\
0 & -1 \\
\end{pmatrix}
\quad \text{and} \quad
\begin{pmatrix}
0 & 1 \\
1 & 0 \\
\end{pmatrix}
$$

Hence, their images in $\mathfrak{S}_4$ are isomorphic to $C_2 \times C_2$. □
3 Galois group

We assume that $p \neq 3$. Let $E$ be an elliptic curve over $K$ with additive, potentially good reduction. We put $L = K(E[3])$ and $G = \text{Gal}(L/K)$. Then $E$ has good reduction over $L$ by Proposition 2.1.

We put

$$g(x) = 3x^4 + b_2x^3 + 3b_4x^2 + 3b_6x + b_8.$$  

Let $\alpha_1, \alpha_2, \alpha_3, \alpha_4$ be the roots of $g(x)$ in $K^{ac}$.

**Proposition 3.1.** (1) The $x$ coordinates of the 8 non-trivial points of $E[3]$ are the roots of $g(x)$.

(2) The set of the third roots of $g$ is

$$\{b_4 - 3(\alpha_1\alpha_2 + \alpha_3\alpha_4), b_4 - 3(\alpha_1\alpha_3 + \alpha_2\alpha_4), b_4 - 3(\alpha_1\alpha_4 + \alpha_2\alpha_3)\}.$$  

(3) The degree $[L : K]$ is not divided by 3 if and only if $\Delta \in (K^\times)^3$.

**Proof.** These are proved in [Ser72, 5.3.b].

We take $\Delta^{1/3} \in K^{ac}$ so that $\Delta^{1/3} \in K$ if $\Delta \in (K^\times)^3$. We assume that $\Delta^{1/3} = b_4 - 3(\alpha_1\alpha_2 + \alpha_3\alpha_4)$ by renumbering $\alpha_1, \alpha_2, \alpha_3, \alpha_4$. We put $K_1 = K(\Delta^{1/3})$, $s = \alpha_1 + \alpha_2$ and $t = \alpha_1\alpha_2$.

**Lemma 3.2.** (1) We have

$$g(x) = (x^2 - sx + t)(3x^2 + (3s + b_2)x - (3t + \Delta^{1/3} - b_4)).$$

(2) We have $[K_1(s, t) : K_1] \leq 2$.

**Proof.** The claim (1) follows from $b_2 = -3(\alpha_1 + \alpha_2 + \alpha_3 + \alpha_4)$ and $\Delta^{1/3} = b_4 - 3(\alpha_1\alpha_2 + \alpha_3\alpha_4)$.

We take a basis of $E[3]$. Then we have an embedding $G \hookrightarrow \text{GL}_2(\mathbb{F}_3)$, and the roots of $g(x)$ correspond to the elements of $\mathbb{P}^1(\mathbb{F}_3)$. By considering $\mathfrak{S}_4$ as the automorphism group of $\{\alpha_1, \alpha_2, \alpha_3, \alpha_4\}$, we have a surjection $\text{GL}_2(\mathbb{F}_3) \to \mathfrak{S}_4$ as in Proposition 2.1.

Then $K_1$ corresponds to the stabilizer in $G$ of the partition $\{\{\alpha_1, \alpha_2\}, \{\alpha_3, \alpha_4\}\}$, which is the intersection of $G$ and a subgroup of $\text{GL}_2(\mathbb{F}_3)$ that is isomorphic to $SD_{16}$. On the other hand, $K_1(s, t)$ corresponds to the stabilizer in $G$ of the subset $\{\alpha_1, \alpha_2\}$, which is the intersection of $G$ and a subgroup of $\text{GL}_2(\mathbb{F}_3)$ that is isomorphic to $D_8$. Therefore, we have $[K_1(s, t) : K_1] \leq |SD_{16}/D_8| = 2$.

We take a non-trivial third root of unity $\zeta_3 \in K^{ac}$.

**Lemma 3.3.** We have $\zeta_3, \Delta^{1/3} \in L$.

**Proof.** We have $\zeta_3 \in L$ by the existence of the Weil pairing, and $\Delta^{1/3} \in L$ by $\Delta^{1/3} = b_4 - 3(\alpha_1\alpha_2 + \alpha_3\alpha_4)$.

The following lemma and proposition are variants of results in [Kra90]. The proofs in [Kra90] work also in our situation. We recall the proofs for completeness.
Lemma 3.4 (cf. [Kra90, Lemme 5]). Let $P$ be a non trivial element of $E[3]$. Then $[L : K(\zeta_3, P)]$ divides 3.

Proof. We take a point $Q$ of $E[3]$ so that $(P, Q)$ is an ordered basis of $E[3]$. Then it gives an injective group homomorphism $\rho: G \to GL_2(\mathbb{F}_3)$. Then the image of $\text{Gal}(L/K(\zeta_3, P))$ under $\rho$ is contained in
\[
\left\{ \begin{pmatrix} 1 & b \\ 0 & 1 \end{pmatrix} \mid b \in \mathbb{F}_3 \right\},
\]
because $\text{det} \rho$ is the mod 3 cyclotomic character. Hence, we have the claim. \[\square\]

Proposition 3.5 (cf. [Kra90, Proposition 3]). Let $K'$ be an extension of $K_1(\zeta_3)$ contained in $L$. Then the followings are equivalent:

1. $[L : K'] \leq 2$.
2. $g(x)$ has a root in $K'$.
3. $g(x)$ has the all roots in $K'$.

Proof. It is trivial that (3) implies (2). We assume (2). Let $\alpha$ be a root of $g(x)$ in $K$. Let $P$ be a point of $E[3]$ whose $x$ coordinate is $\alpha$. Then we have $[L : K'(P)] = 1$ by Proposition 3.1(3) and Lemma 3.4. Hence we have (1).

We assume (1). Taking a basis of $E[3]$, we have an injective group homomorphism $\rho: G \to GL_2(\mathbb{F}_3)$. Then the image of $\text{Gal}(L/K')$ under $\rho$ is contained in
\[
\left\{ \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix} \right\}.
\]
Then, the all roots of $g(x)$ is fixed by the action of $\text{Gal}(L/K')$. Hence, we have (3). \[\square\]

The following lemma is also a variant of a lemma in [Kra90]. Our proof is different from that in [Kra90].

Lemma 3.6 (cf. [Kra90, Lemme 6]). Let $\alpha_0 \in K^\text{ac}$ be a root of $g(x)$. Then $K_1(\zeta_3, \alpha_0)$ contains $s$ and $t$.

Proof. By Lemma 3.5, $K_1(\zeta_3, \alpha_0)$ contains the all roots of $g(x)$. Hence the claim follows. \[\square\]

We simply write $\alpha$ for $\alpha_1$, and take $\beta \in K^\text{ac}$ such that
\[
\beta^2 + a_1\alpha\beta + a_3\beta = \alpha^3 + a_2\alpha^2 + a_4\alpha + a_6.
\]

Lemma 3.7. We have $L = K_1(\zeta_3, \alpha, \beta)$.

Proof. By Lemma 3.4, $[L : K_1(\zeta_3, \alpha, \beta)]$ divides 3. On the other hand, 3 does not divide $[L : K_1]$ by Proposition 3.1(2). Hence the claim follows. \[\square\]
Theorem 3.8. (1) Suppose \( \zeta_3 \in K \) and \( \Delta^{1/3} \in K \).

(a) If \( \alpha \in K \), then \( G \cong C_2 \).

(b) If \( \alpha \notin K \) and \( s, t \in K \), then \( G \cong C_4 \).

(c) If \( K(s, t) \neq K \) and \( \alpha \in K(s, t) \), then \( G \cong C_4 \).

(d) If \( K(s, t) \neq K \) and \( \alpha \notin K(s, t) \), then \( G \cong Q_8 \).

(2) Suppose \( \zeta_3 \in K \) and \( \Delta^{1/3} \notin K \).

(a) If \( \alpha, \beta \in K_1 \), then \( G \cong C_3 \).

(b) If \( \alpha \in K_1 \) and \( \beta \notin K_1 \), then \( G \cong C_6 \).

(c) If \( K_1(s, t) \neq K_1 \), then \( G \cong SL_2(\mathbb{F}_3) \).

(3) Suppose \( \zeta_3 \notin K \) and \( \Delta^{1/3} \notin K \).

(a) If \( \alpha \in K(\zeta_3) \), then \( G \cong C_2 \times C_2 \).

(b) If \( \alpha \notin K(\zeta_3) \), \( s, t \in K(\zeta_3) \) and \( K(s, t) \neq K \), then \( G \cong C_8 \).

(c) If \( K(\zeta_3, s, t) \neq K(\zeta_3) \) and \( s, t \in K \), then \( G \cong D_8 \).

(d) If \( K(\zeta_3, s, t) \neq K(\zeta_3) \) and \( \alpha \in K(\zeta_3, s, t) \), then \( G \cong D_8 \).

(e) If \( K(\zeta_3, s, t) \neq K(\zeta_3) \), then \( \alpha \notin K(\zeta_3) \) and \( G \cong SD_{16} \).

(4) Suppose \( \zeta_3 \notin K \) and \( \Delta^{1/3} \notin K \).

(a) If \( \alpha, \beta \in K_1(\zeta_3) \), then \( G \cong D_6 \).

(b) If \( \alpha \in K_1(\zeta_3) \) and \( \beta \notin K_1(\zeta_3) \), then \( G \cong D_{12} \).

(c) If \( K_1(\zeta_3, s, t) \neq K_1(\zeta_3) \), then \( \alpha \notin K_1(\zeta_3) \) and \( G \cong GL_2(\mathbb{F}_3) \).

Proof. By taking a basis of \( E[3] \), we consider \( G \) as a subgroup of \( GL_2(\mathbb{F}_3) \). We note that (1), (2), (3) and (4) in this theorem correspond the 1st, 3rd, 2nd and 4th column in Proposition 2.1 without mention.

We prove (1). Since \( E \) has bad reduction, the claim (1a) follows from Lemma 3.5. If \( \alpha \notin K \), then \( [L : K] \geq 4 \) by Proposition 3.1(3) and Lemma 3.5. On the other hand, if \( s, t \in K \), then \( [L : K] \leq 4 \) by Lemma 3.4. Hence the claim (1b) follows. By applying Lemma 3.5 to \( K(s, t) \), we have the claims (1c) and (1d).

We prove (2). The claims (2a) and (2b) follows from Lemma 3.7. If \( K_1(s, t) \neq K_1 \), \( [L : K_1] \geq 4 \) by (1c) and (1d). Hence we have (2c), because there is no subgroup of \( SL_2(\mathbb{F}_3) \) with order 12.

We prove (3). By replacing \( K \) by \( K(\zeta_3) \) in (1), we have (3a), (3e), and \( [L : K] = 8 \) in the case (3b), (3c) and (3d). In the case (3b), \( g(x) \) is irreducible by Lemma 3.2(1). Then \( G \) act transitively on the roots of \( g(x) \). Hence we have (3b). In the case (3c),
we have two distinct quadratic extensions $K(\zeta_3)$ and $K(\alpha)$ of $K$. In the case (3d), we have two distinct quadratic extensions $K(\zeta_3)$ and $K(s,t)$ of $K$. Hence we have (3c) and (3d).

By replacing $K$ by $K(\zeta_3)$ in (2), we obtain (4).

**Remark 3.9.** In some case, the inertia subgroup $I$ of $G$ is determined by the Kodaira-Néron type of $E$. In fact, $I \simeq \mathbb{Z}/3\mathbb{Z}$ if and only if the Kodaira-Néron type of $E$ is IV or IV*, where we use the Kodaira symbol after [Kod64]. This fact can be proved similarly as [Kra90, Théorème 2] also in the positive characteristic case.

### 4 Root number

We assume that $K$ is a dyadic field. Let $\phi: \mathbb{F}_2 \to \mathbb{C}^\times$ be the non-trivial character. We take an additive character $\psi: K \to \mathbb{C}^\times$ such that $\psi(a) = \phi(\text{Tr}_{k/F}(\bar{a}))$ for $a \in \mathcal{O}_K$, where $\bar{a}$ denotes the image of $a$ in $k$. Let $d\mu$ be a Haar measure on $K$. Let $\sigma$ be a finite dimensional smooth representation of $W_K$ over $\mathbb{C}$. Then we can consider a local $\epsilon$-factor $\epsilon(\sigma, \psi, d\mu) \in \mathbb{C}^\times$ as in [Del73, §4]. We put

$$w(\sigma, \psi) = \frac{\epsilon(\sigma, \psi, d\mu)}{\epsilon(\sigma, \psi, d\mu)};$$

which is independent of the choice of $d\mu$. We call $w(\sigma, \psi)$ the local root number of $\sigma$ with respect to $\psi$. For a finite extension $F$ over $K$ and a finite dimensional smooth representation of $W_F$ over $\mathbb{C}$, we always consider the root number with respect to $\psi \circ \text{Tr}_{F/K}$. We simply write $w(\sigma)$ for $w(\sigma, \psi)$ in the sequel.

Let $T_3(E)$ be the 3-adic Tate module of $E$. We put $V_3(E) = T_3(E) \otimes_{\mathbb{Z}_3} \mathbb{Q}_3$. We take an embedding $\mathbb{Q}_3 \to \mathbb{C}$. Then the natural action of $W_K$ on $V_3(E)$ induces a smooth representation

$$\sigma_E: W_K \to \text{Aut}(V_3(E) \otimes_{\mathbb{Q}_3} \mathbb{C}),$$

because $E$ has potentially good reduction. We put $w(E/K) = w(\sigma_E)$, which is called the local root number of $E$.

Using results in Section 3, we can extend results in [DD08] to positive characteristic cases. Here, we treat only the most non-trivial case, where $G \simeq GL_2(\mathbb{F}_3)$.

**Remark 4.1.** Our choice of $\psi$ is different from that in [DD08]. It is the reason why the formulas in Lemma 4.2 and Theorem 4.6 look different from those in [DD08].

We assume that $G \simeq GL_2(\mathbb{F}_3)$. We put $f = [k : \mathbb{F}_2]$ and $n(E) = v(\Delta)$. We note that $f$ is odd and $K(\zeta_3)$ is the unramified quadratic extension by the assumption. Let $\eta: W_K \to \mathbb{C}^\times$ be the unramified character that sends the arithmetic Frobenius to $(\sqrt{2}i)^f$. We put $\sigma_{E, \eta} = \sigma \otimes \eta^{-1}$.

**Lemma 4.2** (cf. [DD08, Lemma 1]). The $W_K$-representation $\sigma_{E, \eta}$ factors through $G$. Moreover, we have

$$w(E/K) = (-i)^f(n(E)-2)w(\sigma_{E, \eta}).$$
Proof. The proof in [DD08, Lemma 1] works also in our situation.

Lemma 4.3. The discriminant of $g(x)$ is equal to $-27\Delta^2$.

Proof. Using Proposition 3.1(2), we see that the discriminant of $g(x)$ is equal to

$$3^6 \prod_{1 \leq i < j \leq 4} (\alpha_i - \alpha_j)^2 = (\Delta^{1/3} - \zeta_3 \Delta^{1/3})^2 (\Delta^{1/3} - \zeta_3^2 \Delta^{1/3})^2 (\Delta^{1/3} - \zeta_3^2 \Delta^{1/3})^2 = -27\Delta^2.$$

We put

$$s' = \zeta_3 (\alpha_1 + \alpha_2) + \zeta_3^2 (\alpha_3 + \alpha_4),$$
$$t' = \zeta_3 \alpha_1 \alpha_2 + \zeta_3^2 \alpha_3 \alpha_4$$

and $M = K_1(s', t')$.

Lemma 4.4. We have an isomorphism $\text{Gal}(L/M) \simeq C_8$.

Proof. Let $h_0$ be the element of $S_4 = \text{Aut} \{\alpha_1, \alpha_2, \alpha_3, \alpha_4\}$ defined by

$$\alpha_1 \mapsto \alpha_3 \mapsto \alpha_2 \mapsto \alpha_4 \mapsto \alpha_1.$$

Let $H$ be the preimage of the subgroup generated by $h_0$ under $G \to S_4$. Then $H$ is isomorphic to $C_8$ by Proposition 2.1. Any lift of $h_0$ in $G$ send $\zeta_3$ to $\zeta_3^2$, because it fixes $\Delta^{1/3}$ and permutes $\zeta_3 \Delta^{1/3}$ and $\zeta_3^2 \Delta^{1/3}$. Hence, $H$ fixes $s'$ and $t'$ by the definition. This implies that $H \subset \text{Gal}(L/M)$ and $[M : K_1] \leq 2$. Therefore, it suffices to show $M \neq K_1$.

Since $K_1(s, t) \neq K_1$ by the assumption $G \cong GL_2(\mathbb{F}_3)$, either

$$\alpha_1 + \alpha_2 \neq \alpha_3 + \alpha_4 \quad \text{or} \quad \alpha_1 \alpha_2 \neq \alpha_3 \alpha_4$$

holds. Hence, $M$ is not fixed by $\text{Gal}(L/K_1)$. This show $M \neq K_1$.

Let $E$ be the elliptic curve over $\mathbb{F}_2$ defined by $x^3 = y^2 + y$. The following fact is well-known:

Lemma 4.5 (cf. [IT12]). Let $m$ be a positive integer. Then we have $\sharp E(\mathbb{F}_{2m}) = 2^m + 1 - (\sqrt{2}i)^m - (-\sqrt{2}i)^m$.

By Lemma 4.2, we consider $\Sigma_{E, \eta}$ as a representation of $G$. We take a character $\chi \colon \text{Gal}(L/M) \to \mathbb{C}^\times$ such that $\Sigma_{E, \eta}|_{\text{Gal}(L/M)}$ is the direct sum of $\chi$ and its conjugate. For a character $\phi$ of a subgroup of $G$, let $w(\phi)$ denote the root number of the character of the Weil group corresponding to $\phi$. For a finite extension $F$ of $K$ and its quadratic extension $F'$, let $w_{F'/F}$ be the root number of the non-trivial character of $W_F$ that factors through $\text{Gal}(F'/F)$. The following is a main theorem, which is proved at [DD08, Theorem 7] in the case where $K$ is of characteristic 0.
Theorem 4.6. We have

\[ w(E/K) = (-i)^{f(n(E)-2)} \frac{w(\chi)}{w_K(\alpha,\beta)/K(\alpha)}, \]

where \( f \) and \( n(E) \) are defined after Remark 4.1.

Proof. We take an ordered basis \((P, Q)\) of \(E[3]\) such that the coordinate of \(P\) is \((\alpha, \beta)\).
We identify \(G\) with \(GL_2(F_3)\) by this ordered basis. By Lemma 4.2, it suffices to show

\[ w(\sigma_{E,\eta}) = w(\chi) w_{K(\alpha,\beta)/K(\alpha)}. \quad (4.1) \]

Let \(B_{12} \subset GL_2(F_3)\) be the \(F_3\)-rational points of the upper triangle Borel subgroup of \(GL_2\). Let \(\det_{B_{12}}\) be the determinant character, and \(\sigma_{B_{12}}\) be the non-trivial character that factors through

\[ B_{12} \rightarrow F_3^\times; \begin{pmatrix} a & b \\ 0 & d \end{pmatrix} \mapsto a. \]

We take a non-trivial character \(\tau\) of \(SL(F_3)\). (We note that the abelianization of \(SL(F_3)\) is isomorphic to \(\mathbb{Z}/3\mathbb{Z}\).) Let \(k_2\) be the residue field of \(K(\zeta_3)\). By the local class field theory, \(\tau\) corresponds to a non-trivial character \(\chi_\tau\) of \(k_2^\times/\mathbb{Z}_3\). Then

\[ w(\sigma_{E,\eta}) = w(\chi) w(\det_{B_{12}}) w(\tau) \]

is proved in the proof of [DD08, Theorem 7] without using the assumption that the characteristic of \(K\) is 0. Since \(B_{12}\) is the subgroup of \(G\) preserving the subgroup of \(E[3]\) generated by \(P\), we have \(w(\sigma_{B_{12}}) = w_{K(\alpha,\beta)/K(\alpha)}.\) We have

\[ w(\det_{B_{12}}) = w_{K(\alpha,\zeta)/K(\alpha)} = (-1)^{[K(\alpha,\zeta)/K] - v(D(\mathcal{O}(K(\alpha)/K)) = 1, \]

where we have the second equality by [BH06, 23.5. Lemma 1 and Proposition], and the third equality holds since \(v(D(\mathcal{O}(K(\alpha)/K))\) is even by Lemma 4.3. We put \(q = p^f\). We have

\[ w(\tau) = q^{-1} \sum_{x \in k_2^\times} \chi_\tau(x)^{-1} \phi(\text{Tr}_{k_2/F_2}(x)) \]

\[ = q^{-1} \left\{ \sum_{x \in (k_2^\times)^3} \phi(\text{Tr}_{k_2/F_2}(x)) - \sum_{x \in \zeta_3(k_2^\times)^3} \phi(\text{Tr}_{k_2/F_2}(x)) \right\} \quad (4.3) \]

using [BH06, 23.5. Theorem] and that

\[ \{ x \in \zeta_3(k_2^\times)^3 \mid \text{Tr}_{k_2/F_2}(x) = 0 \} \rightarrow \{ x \in \zeta_3^2(k_2^\times)^3 \mid \text{Tr}_{k_2/F_2}(x) = 0 \}; \ x \mapsto x^2 \]

is a bijection. We put

\[ N_1 = \{ y \in k_2 \mid y + y^2 \in (k_2^\times)^3 \}; \]

\[ N_2 = \{ y \in k_2 \mid y + y^2 \in \zeta_3(k_2^\times)^3 \}. \]
We note that \( N_2 = (q^2 - 2 - N_1)/2. \) Then (4.3) is equal to

\[
q^{-1}\left\{ \left( \frac{N_1}{2} - \left( \frac{q^2 - 1}{3} \right) \right) - \left( \frac{N_2}{2} - \left( \frac{q^2 - 1}{3} - \frac{N_2}{2} \right) \right) \right\} = \frac{3N_1 - q^2 + 2}{2q} = 1,
\]

because \( N_1 = (q^2 + 2q - 2)/3 \) by Lemma 4.5. Therefore (4.1) follows from (4.2).

Remark 4.7. The elliptic curve \( E \) appears in a semi-stable reduction of a Lubin-Tate curve over a dyadic field (cf. \([IT11]\)). Hence, it is studied in \([IT12]\). Actually, a similar calculation as the calculation of \( w(\tau) \) in the proof of Theorem 4.6 appears in \([IT12]\).
