Abstract. The general form of the operators commuting with the ground representation (appearing in many physical problems within single particle approximation) of the group is found. With help of the modified group projector technique, this result is applied to the system of identical particles with spin independent interaction, to derive the Dirac-Heisenberg hamiltonian and its effective space for arbitrary orbital occupation numbers and arbitrary spin. This gives transparent insight into the physical contents of this hamiltonian, showing that formal generalizations with spin greater than 1/2 involve nontrivial additional physical assumptions.

1. Introduction

Considering systems of identical electrons interacting by Coulomb forces only, Dirac found \[ H = U + \sum_{k<l} J_{kl} \mathbf{s}_k \cdot \mathbf{s}_l \] that the effective hamiltonian can be expressed in the spin space only: \[ H = U + \sum_{k<l} J_{kl} \mathbf{s}_k \cdot \mathbf{s}_l \], where \( \mathbf{s}_i \) is vector of the Pauli matrices related to the spin in the \( i \)-th site. The aim of this paper is to present rigorous derivation of the Dirac-Heisenberg hamiltonian for any spin, within the framework of the original physical assumptions. This means that arbitrary spin independent interaction of the identical particles is considered. Then, due to the perturbative approach, the hamiltonian is approximately reduced in the subspaces of the orbital state space spanned by the vectors with the same occupation number. Such subspace carries special induced type representation (ground representation) of the permutational group, commuting with the reduced hamiltonian. The general form of the operator commuting with the ground representation is derived in
‡ e-mail: yqoq@afrodita.rcub.bg.ac.yu
section 2, and the result is applied to the considered Hamiltonian in section 3, yielding its form in the orbital many particle factor space. Finally, the wanted form of the Hamiltonian is obtained in the section 4, by the restriction to the relevant (symmetrized or antisymmetrized) subspace of the total space. This step is based on the modified group projector technique for the induced representations.

The result generalizes the original derivation with respect to spin and occupation numbers. Nevertheless, the physical framework remains the same, in contrast to the formal generalizations appearing in various theories of magnetic materials [2], when in the Dirac-Heisenberg Hamiltonian only the values of spin and the interaction coefficients are appropriately modeled.

The rest of the introduction gives the necessary reminder on the modified group projector technique. Let $D(G)$ be representation of the group $G$ in the space $\mathcal{H}_D$, decomposing into the irreducible components $D^{(\mu)}(G)$ as $D(G) = \bigoplus_{\mu=1}^r a_{\mu} D^{(\mu)}(G)$ ($a_{\mu}$ is the frequency number of $D^{(\mu)}(G)$). The symmetry adapted [3, 4] (or standard) basis $\{|\mu t_{\mu} m\rangle | \mu = 1, \ldots, r; \ t_{\mu} = 1, \ldots, a_{\mu}; \ m = 1, \ldots, |\mu|\}$ ($|\mu|\) denotes the dimension of $D^{(\mu)}(G)$) in $\mathcal{H}_D$ is defined by the following condition:

$$D(g) |\mu t_{\mu} m\rangle = \sum_{m'=1}^{|\mu|} D^{(\mu)}_{m'm}(g) |\mu t_{\mu} m'\rangle.$$  \hspace{1cm} (1)

To find this basis [3], the auxiliary representation $\Gamma^{\mu}(G) \overset{\text{def}}{=} D(G) \otimes D^{(\mu)^*}(G)$ in the space $\mathcal{H}_D \otimes \mathcal{H}^{(\mu)^*}$ is constructed for each irreducible component $D^{(\mu)}(G)$ (with $a_{\mu} > 0$) of $D(G)$. Here, $D^{(\mu)^*}(G)$ is the dual representation of $D^{(\mu)}(G)$; in fact, it is the conjugated one, since the finite permutational groups and their unitary representations are considered. The range of the modified projector $G(\Gamma^{\mu}) \overset{\text{def}}{=} \frac{1}{|G|} \sum_g \Gamma^{\mu}(G)$ is the ($a_{\mu}$ dimensional) subspace $\mathcal{F}^{\mu}$ of the fixed points for the representation $\Gamma^{\mu}(G)$. For the arbitrary basis $\{|\mu t_{\mu}\rangle | \mu = 1, \ldots, a_{\mu}\}$ of $\mathcal{F}^{\mu}$, the subbasis $\{|\mu t_{\mu} m\rangle | m = 1, \ldots, |\mu|\}$ is found by the partial scalar product with the standard vectors $|\mu m\rangle$ of the irreducible representation:

$$|\mu t_{\mu} m\rangle = \langle \mu m \ | \mu t_{\mu} \rangle.$$ \hspace{1cm} (2)

If $G$ is the symmetry group of the Hamiltonian $H$ (thus $[D(g), H] = 0$ for each $g \in G$), then taking for $|\mu t_{\mu}\rangle$ an eigen basis of $H \otimes I_{\mu}$ ($I_{\mu}$ is the identity in $\mathcal{H}^{(\mu)^*}$), eq. (2) gives the symmetry adapted eigen basis for $H$: $H |\mu t_{\mu} m\rangle = E_{\mu t_{\mu}} |\mu t_{\mu} m\rangle$. 

The representations involved in the paper are of the induced type. Precisely, let $K$ be subgroup of $G$ with the transversal $Z = \{ z_t \mid t = 0, \ldots, |Z| - 1 \}$ ($z_0$ is the identity of the group, $|Z| = |G|_K$). Then $D(G) = \Delta(G) \otimes d(G)$, where $\Delta(G) = \Delta'(K \uparrow G)$ is induced representation and $d(G)$ is some other representation of $G$. In this case the modified projectors can be reduced [3] to the subgroup modified projector representation $\gamma \in \mathcal{R}$ in the $\left(\text{left (permutational)}\right)$ action of $G$ is induced representation and $d(G)$ is some other representation of $G$. It appears that the range of $K$ the effective hamiltonian is $H^\mu = B^\mu \{ E^{00} \otimes K(\gamma^\mu) \} B^\mu$.\(^{\ (3)}\)

Here, $B^\mu \overset{\text{def}}{=} \frac{1}{\sqrt{|Z|}} \sum_{z_t} E^{00} \otimes I_\Delta \otimes d(z_t) \otimes D(\gamma^\mu)^*(z_t)$ is partial isometry, and $E^{00} = |z_t \rangle \langle z_0|$ are $|Z|$-dimensional square matrices with only one non-vanishing element ($E^{00})_{t0} = 1$. It appears that the range of $K(\gamma^\mu)$ (the subspace in $\mathcal{H}_{\gamma^\mu}$) is the effective space, while the effective hamiltonian is $H^\mu = B^\mu (H \otimes I_\mu) B^\mu K(\gamma^\mu)$. Indeed, the symmetry adapted eigen subbasis $|\mu t_\mu m\rangle$ corresponding to the irreducible representation $D(\gamma^\mu)(G)$ is found by (3) with the vectors $|\mu t_\mu \rangle = B^\mu |\mu t_\mu\rangle_0^0$, where $|\mu t_\mu\rangle_0^0$ are the eigen vectors of $H^\mu$ from the range of $K(\gamma^\mu)$: $H^\mu |\mu t_\mu\rangle_0^0 = E_{\mu t_\mu} |\mu t_\mu\rangle_0^0$.\(^{\ (3)}\)

2. Invariants of group representations

If $K$ is subgroup in the finite group $G$, its left transversal $Z$ gives the coset partition $G = \sum_t z_t K$. Therefore, to each element $g \in G$ corresponds one element $\overline{g}$ of $Z$: there are uniquely defined $k \in K$ and $z_t \in Z$, such that $g = z_t k$, and $z_t$ is denoted by $\overline{g}$. Together with this coset decomposition, the subgroup $K$ gives the double-coset decomposition [7, 8, 9] of $G$ over $K$: $G = \sum_\lambda K z_\lambda K$. Each double-coset decomposes onto one or more cosets, $K z_\lambda K = \sum_m z_{\lambda m} K$. Thus, the double-coset representatives can be chosen among the elements of the transversal $Z$. The double-coset decomposition enables to define for each $g \in G$ its double-coset representative $z_\lambda$ by $g = k \lambda k'$ ($k, k' \in K$), denoted also as $\overline{g}$.

Furthermore, each $g \in G$, and $z_m \in Z$ define uniquely $z_s \in Z$ and $k \in K$, such that $g z_m = z_s k$. Obviously, with the above notational convention, $z_s = \overline{g z_m}$, and the left (permutational) action of $G$ over $Z$ becomes $g : z_m \mapsto \overline{g z_m}$. This action is faithfully represented by the linear operators of the left ground representation $L(G) = 1(K \uparrow G)$ in the $|Z|$-dimensional vector space, $Z$: each element of $z_m \in Z$ is mapped to the basis vector $|z_m \rangle$. The operators of $G$ are defined by $L(g) \mid z_m \rangle \overset{\text{def}}{=} \mid g z_m \rangle$, i.e.
\[ L(g) = \sum_m |g z_m\rangle \langle z_m|. \] The homomorphism condition \( L(gg') = L(g)L(g') \) is easily checked.

Also, the right multiplication \( z_mg = z_k \) introduces the ”right” operators \( R(g): \langle z_m| R(g) \equiv (\overline{\langle z_mg|}), \text{ or } R(g) = \sum_m z_m \langle \overline{z_mg}|. \] These operators form antirepresentation \((R(g)R(g') = R(g'g))\) if and only if \( K \) is invariant subgroup. Since \( \overline{z_s z_m k} = \overline{z_s z_m} \), it turns out that \( R(z_m k) = R(z_m) \) for each \( k \in K \), i.e. that the mapping \( g \mapsto R(g) \) is function over the cosets of \( K \).

All the operators \( L(g) \) and \( R(g) \) are in the basis \( \{|z_m\}\) given by the real matrices, with elements 0 or 1. Especially, for the unitary (in fact orthogonal) matrices \( L(g) \) this yields \( L(g)^T = L(g^{-1}) \).

Now, the condition that the operator \( A \) acting in \( Z \) is invariant of \( G \) means that \([A, L(g)] = 0 \) for each \( g \in G \). Such an operator has very special form.

**Theorem 1** Any invariant operator \( A \) in \( Z \) is of the form \( A = \sum_{g \in G} \alpha(\overline{g}) R(g), \) where \( \alpha(\overline{g}) \) is function over double-cosets of \( K \) in \( G \) (i.e. these constants can be independently chosen one for each double-coset).

The proof consists of two parts. At first, the commutation with the operators \( L(z_m) \) representing the transversal is used: because of \( L(z_m) |z_0\rangle = |\overline{z_m^{-1} z_0}\rangle = |z_m\rangle \), one has \[ A = \sum_{m,n} \langle m| A |n\rangle |m\rangle \langle n| = \sum_{m,n} \langle z_0| L^T(z_m) A |n\rangle |m\rangle \langle n|. \] Since \( z_m^{-1} \) is also an element of \( G \), it commutes with \( A \), and

\[ A = \sum_{mn} \langle z_0| A |z_s\rangle \langle z_s| L^T(z_m) |z_n\rangle \langle z_m|zent\rangle = \sum_{ms} A_{0s} |z_m\rangle \langle z_m z_s|, \]

giving finally \( A = \sum_s A_{1s} R(z_s) \). Consequently, the matrix of the invariant \( A \) is completely determined by its first row. Secondly, the subgroup elements are employed; for each double-coset representative \( z_\lambda \) and each element \( k \in K \) it holds

\[ A_{0\lambda} = \langle z_0| A |z_\lambda\rangle = \langle z_0| L(k) A |z_\lambda\rangle = \langle z_0| A L(k) |z_\lambda\rangle = \langle z_0| A |k z_\lambda\rangle. \]

When \( k \) goes over \( K \), all the elements \( k z_\lambda \) go over the coset representatives of the whole double-coset of \( z_\lambda \), meaning that the matrix elements \( A_{0s} \) and \( A_{0t} \) must be same if \( z_t \) and \( z_s \) are from the same double-coset. Together with the previous conclusion this gives \( A = \sum_\lambda A_{0\lambda} \sum_m R(z_{\lambda m}) \). To complete the proof, it remains to recall that the right operators are same for the elements of the same coset.
From the theorem immediately follows that the number of linearly independent invariants is equal to the number of double-cosets of $K$. Precisely, to each double-coset represented by $z_{\lambda}$, there corresponds the invariant $A_{\lambda} = \sum_{g \in Kz_{\lambda}K} R(g)$. In the special case, when $K = \{e\}$, the trivial subgroup containing the identity only, the ground representation is the regular representation of the group; since in this case each element of the group is itself one coset and one double-coset, there are exactly $|G|$ independent invariants, each of them being one of the operators $R(g)$ (in this case $R(g^{-1})$ form the right regular representation of $G$, being equivalent to the left one $L(G)$), and all the left operators commute with all the right ones.

3. Generalized Dirac-Heisenberg hamiltonian

Let $\mathcal{H} = \mathcal{H}_o \otimes \mathcal{H}_s$ be the quantum mechanical state space of some particle, where $\mathcal{H}_o$ and $\mathcal{H}_s$ are the orbital and the spin factor spaces. Then, for the system of $N$ particles the tensor powers $\mathcal{H}_o^N \overset{\text{def}}{=} \mathcal{H}_o \otimes \cdots \otimes \mathcal{H}_o$ ($N$ times) and $\mathcal{H}_s^N$ are constructed, and in the space $\mathcal{H}^N = \mathcal{H}_o^N \otimes \mathcal{H}_s^N$ the symmetric (bosons) or antisymmetric (fermions) part are considered as the state space of the total system. If $\{|i\rangle | i = 1, \ldots, o\rangle\}$ is a basis in $\mathcal{H}_o$, then $\{|i_1, \ldots, i_n\rangle \overset{\text{def}}{=} |i_1\rangle \cdots |i_n\rangle |i_1, \ldots, i_N = 1, \ldots, o\rangle\}$ is a basis in $\mathcal{H}_o^N$. Each of this vectors defines the occupation number vector $\mathbf{n} = (n_1, \ldots, n_{|o|})$, with the component $n_i$ showing the number of particles being in the state $|i\rangle$.

Each permutation $\pi$ of the symmetric group $S_N$, is represented by the operator $\Delta(\pi)$, defined by the action $\Delta(\pi) |i_1, \ldots, i_N\rangle \overset{\text{def}}{=} |i_{\pi^{-1}1}, \ldots, i_{\pi^{-1}N}\rangle$. This action does not change the occupation number of the basis vectors, and exactly the orbit of the action gives the set of the basis vectors with the same occupation numbers. Thus, each orbit is uniquely defined by the occupation number and spans the subspace $\mathcal{H}_n^N$ invariant for the representation $\Delta(S_N)$. Consequently, $\Delta(S_N)$ is in $\mathcal{H}_n^N$ reduced to the representation $\Delta_n(S_N)$. Its dimension is equal to the order of the orbit with the occupation number $\mathbf{n}$, $|\Delta_n| = \frac{N!}{n_1! \cdots n_{|o|}!}$, since the stabilizer of the vector with the occupation number $\mathbf{n}$ is $S_{|\mathbf{n}|}^n = S_{n_1} \otimes \cdots \otimes S_{n_{|o|}}$, this is. Note that, being induced from the trivial representation of the stabilizer, $\Delta_n(S_N) = 1(S_N \uparrow S_{|\mathbf{n}|})$, $\Delta_n(S_N)$ is a ground representation $\mathcal{H}_n^N$.

To summarize, the space $\mathcal{H}_o^N$ is decomposed to the orthogonal sum $\mathcal{H}_o^N = \oplus_n \mathcal{H}_n^N$. In each of these subspaces acts the ground representation $\Delta_n(S_N)$, and the partial
reduction of the representation $\Delta(S_N)$ is obtained: $\Delta(S_N) = \oplus_n \Delta_n(S_N)$.

Let $H$ be spin-independent hamiltonian of the system of $N$ identical particles. It is written in the form $H = H_1 + H_2$, where $H_1 = \sum_{s=1}^{N} h_s$ is the noninteracting part. Here, $h_i$ is one particle hamiltonian, i.e. the operator in the space $H_o$, while $H_2 = \sum_{s<t} V_{st}$ describes two-particle interaction. Since $H$ commutes with the operators $\Delta(S_N)$, all $h_s$ must be equivalent: the full form of $h_s$ is the tensor product of the identity operators in all the spaces except in the $s$-th one, where the corresponding factor is same, e.g. $h$. Analogously, all the operators $V_{st}$ are same except that their nontrivial action is reduced to the different pair of spaces.

If the basis $\{|\bar i\rangle\}$ is chosen as the eigen basis of $h$ (with the eigenvalues $\epsilon_i$), then the vectors of the subspace $H^N_n$ are the eigenvectors of $H_1$ for the eigenvalue $E_n = \sum_{i=1}^{d} n_i \epsilon_i$. Although this subspace need not be invariant for $H_2$, the approximation $H_2 \approx \oplus_n H_{2n}$, with $H_{2n} = P_n H_2 P_n$ ($P_n$ stands for the projector onto $H^N_n$) enables the perturbative approach, involving the eigen problems of the operators $H_{2n}$. Since $H_2$ is invariant of $S_N$ in the whole space $H^N_0$, the operators $H_{2n}$ are also $S_N$-invariants, i.e. they commute with the corresponding representation $\Delta_n(S_N)$. Recalling that this is ground representation, the theorem [1] gives the most general form

$$H_{2n} = \sum_{\pi \in S_N} \alpha(\overline{\pi}) R_n(\pi). \quad (4)$$

Here, $R_n(\pi)$ are the right operators of $\Delta_n(\pi)$, while the coefficients $\alpha$ are equal for all the permutations from the same double-coset of $S_N^n$.

Until now, only the orbital space $H^N_0$ has been considered, since the hamiltonian acts trivially in the spin factors. Nevertheless, the particles are identical, and either the symmetrized or the antisymmetrized part of the total space $H^N$ is to be considered. The orbital occupation number decomposition yields the decomposition of the total space: $H^N = \oplus_n H^N_n \otimes H^N_s$. Using arbitrary basis $\{|\sigma\rangle \mid \sigma = 1, \ldots, 2s + 1\}$ in the single particle spin space $H_s$, the representation $d(S_N)$ in $H^N_s$ is defined analogously to $\Delta(S_N)$ in $H^N_0$: $d(\pi) |\sigma_1, \ldots, \sigma_N\rangle \overset{\text{def}}{=} |\sigma_{\pi^{-1}1}, \ldots, \sigma_{\pi^{-1}N}\rangle$, and in the total space the permutation $\pi$ is represented by the operator $\Delta(\pi) \otimes d(\pi)$. Obviously the subspaces $H^N_n \otimes H^N_s$ are invariant for the action of $\Delta \otimes d$, and the modified group projector of the irreducible
representation $D^{(\mu)}(S_N)$
\[ S_N(\Delta \otimes d \otimes D^{(\mu)*}) = \frac{1}{N!} \sum_{\pi} \Delta(\pi) \otimes d(\pi) \otimes D^{(\mu)*}(\pi) = \otimes_n S_N(\Delta_n \otimes d \otimes D^{(\mu)*}) \] (5)

independently treats each of these subspaces. Therefore, in each subspace $H^N \otimes H^N \otimes H^{(\mu)*}$ there is the subspace $H^\mu$ corresponding to the representation $D^{(\mu)}(S_N)$. It is spanned by the standard subbasis $\{|\mu t; \mu m\rangle\}$, obtained by (2) from any basis $\{|n; \mu t\rangle\}$ of the range $F^\mu_n$ of the projector $S_N(\Delta_n \otimes d \otimes D^{(\mu)*})$; obviously, $F^\mu_n$ is the intersection of $H^N \otimes H^N \otimes H^{(\mu)*}$ and the range $F^\mu$ of the projector (3). Especially, taking the identity and the alternating representations, $D^{(\pm)}(\pi) = (\pm)^\pi$ (as usual, $\pi$ in the exponent denotes the parity of $\pi$) for $D^{(\mu)}(S_N)$, the projector (3) becomes the symmetrizer and antisymmetrizer, respectively; in these cases of one dimensional irreducible representations $F^\pm_n$ is itself the subspace $H^\pm_n$.

4. Restriction to the relevant subspace

Since the involved representations are of the induced type, the modified group projector technique isomorphically relates by eq. (3) the subspace $F^\mu_n$ of $H^N \otimes H^N \otimes H^{(\mu)*}$ to the effective subspace, being the range of the subgroup projector $K(\gamma^\mu)$ in $H^N \otimes H^{(\mu)*}$ (since $\Delta'(K)$ is trivial representation). Of course, in the space $H^N \otimes H^{(\mu)*}$ acts the effective hamiltonian $H^\mu_n$, with the range contained in $F^\mu_n$. Especially, for the physically important representations $D^{(\pm)}(S_N)$, the effective hamiltonian $H^\pm_n$ acts in the spin space $H^N_s$, as well as $K(\gamma^\pm)$.

Precisely, in the considered context $G = S_N$, $K = S^p_N$, $\Delta'(K) = 1(S^p_N)$ and $d(S_N)$ is the permutational representation in the spin space. Thus,
\[ B^\mu_n = \frac{1}{\sqrt{|Z|}} \sum_{t} |z_t\rangle \langle z_0| \otimes d(z_t) \otimes D^{(\mu)*}(z_t) \]

(omitted number 1 standing for $\Delta'$). Then, skipping the factor $E^{00} = |z_0\rangle \langle z_0|$ (this only precisely gives the space of action of $H^\mu_{2n}$), one finds:
\[ B^\mu_n (H_{2n} \otimes I_\mu) B^\mu_n = \frac{1}{N!} \sum_{p,t} \alpha(\pi) \langle z_t | R(\pi) | z_p\rangle d(z_t^{-1} z_p) \otimes D^{(\mu)*}(z_t^{-1} z_p). \]

The matrix element of $R(\pi)$ is obviously $\langle z_t | z_p\rangle = \delta_{z_t, z_p\pi}$ (Kronecker delta). When the sum over $\pi = z_q \kappa$ is decomposed onto the sums over transversal ($q$) and stabilizer
ON THE DIRAC-HEISENBERG MODEL

(κ), the equality $z_1z_2z_κ = z_1z_κ$ for $κ ∈ S_N^n$ shows that all the terms are independent of $κ$. Thus:

$$B^n_µ(H_{2n} \otimes I_µ)B^n_µ = \frac{1}{|Z|} \sum_{q,t} \alpha(z_q) d(z_t^{-1} z_κ z_q) \otimes D^{(µ)*}(z_t^{-1} z_κ z_q).$$

Since the element $z_t^{-1} z_κ z_q$ can be written in the form $z_q κ'$ (i.e. it is from the coset represented by $z_q$), multiplication by $S_N^n(d \otimes D^{(µ)*})$ gives:

$$H^{(µ)}_{2n} = \frac{|Z|}{N!} \sum_q \sum_κ \alpha(z_q) d(z_q κ) \otimes D^{(µ)*}(z_q κ),$$

and finally,

$$H^{(µ)}_{2n} = \frac{1}{n_1! \cdots n_{|ο|}!} \sum_π \alpha(π) d(π) \otimes D^{(µ)*}(π). \quad (6)$$

This relation is in fact the most general form of the $µ$-th component of the permutational invariant hamiltonian acting in $H_N^n \otimes H_N^s$, being trivial in $H_N^s$. Note that this operator acts in the space isomorphic to the direct product of $H_N^n$ and the space of the representation $D^{(µ)}(S_N)$. Still, the range of the projector $K(γ^µ) = \frac{1}{n_1! \cdots n_{|ο|}!} \sum_κ γ^µ(κ)$ is the effective part of this space (its orthocomplement is from the kernel of $H^{(µ)}_{2n}$).

Finally, let it be stressed again that the coefficients $α$ can be deliberately chosen only one for each double-coset of $S_N^n$.

Physically relevant are two simplifications. At first, as it has been mentioned already, the irreducible representation $D^{(µ)}(S_N)$ is actually either the symmetric or the antisymmetric one, giving:

$$H^{±}_{2n} = \frac{1}{n_1! \cdots n_{|ο|}!} \sum_π (±)^π \alpha(π) d(π). \quad (7)$$

In these cases, the effective space of $H^{±}_{2n}$ is subspace in the spin space $H^s_N$.

The second one is that only two particle interaction are considered, meaning that only the permutations of at most two particles are involved in (4). With $τ_{kl}$ denoting the transposition of the particles $k$ and $l$, expressions (4) and (7) become

$$H_{2n} = \alpha(e) I + \sum_{l<k} \alpha(τ_{lk}) R_n(τ_{lk}),$$

and

$$H^{±}_{2n} = \frac{1}{n_1! \cdots n_{|ο|}!} \left[ \alpha(e) I ± \sum_{k<l} \alpha(τ_{kl}) d(τ_{kl}) \right]. \quad (8)$$
5. Concluding remarks

Originally, the hamiltonian (8) is derived \[1\] for the case when the orbital occupation numbers \(n_i\) are at most 1, meaning that \(S_N^n\) is the trivial subgroup \(\{e\}\), and therefore \(\Delta_n(S_N)\) is the regular (\(N!\)-dimensional) representation of \(S_N\). In this case the coefficients \(\alpha\) can be chosen arbitrary, since each element of \(S_N\) is itself one double-coset. Further, in this case the group projector \(K(\gamma^\pm)\) is the identity operator in the space \(\mathcal{H}_s^N\), meaning that the whole spin space is efficient.

Of course, for spin \(s = 1/2\) the transposition \(\tau_{ij}\) is in the space \(H_s^N\) represented by the operator \(d(\tau_{ij}) = \frac{1}{2}(I + s_i \cdot s_j)\), and (8) takes the usual form

\[
H_{2n}^- = U + \sum_{k<l} J(\tau_{kl}) s_k \cdot s_l.
\]

Although the same form is frequently used \[2\] with the spin operators for \(s \neq 1/2\), these formal generalizations do not preserve the original physical meaning of the Heisenberg-Dirac hamiltonian: the resulting operator cannot be derived from the pure orbital interaction of the identical particles (for higher spin the transpositions cannot be expressed by the spin matrices in the same form). Even for \(s = 1/2\), the interaction coefficients can be independently chosen for any pair of sites only for the occupation numbers \(n_i \leq 1\); in other cases, they must be same over the same double coset of \(S_N^n\), while the relevant space is only subspace of the total spin space \(\mathcal{H}_s^N\), which can be easily found with help of the subgroup projector \(S_N^n(d \otimes D^{\pm})\). Indeed, using the direct product factorization of the group \(S_N^n\), the projector can be written in the form:

\[
S_N^n(d \otimes D^{\pm}) = \otimes_{i=1}^{[\alpha]} S_{n_i}(d \otimes D^{\pm}).
\]

Each of the factors may be straightforwardly found; moreover, only the generating transpositions may be involved \[3\]. This simple restriction to the relevant space may be used to reduce the time in various numerical calculations.

Finally, let it be emphasized that the general form of the hamiltonian acting in the space of the ground representation of the symmetry group (thus commuting with it), given by the theorem \[4\] is the result important independently of the Dirac-Heisenberg hamiltonian. Indeed, this situation occurs in the context of the single particle approximations \[4\], e.g. when the tight-binding electronic levels, spin waves or normal vibrations modes are calculated: then the symmetry group action can be factorized onto the permutational part \(D^p(G)\) and interior part \(D^{\text{int}}(G)\). The later is related to
the phenomena considered (this is polar and axial vector representation of the group in the case of normal modes and spin waves, and the representation carried by the atomic orbitals from the same site in the electronic tight binding calculations). The former describes the geometry of the system showing how the transformations of the group map one site into another, and this is always the ground representation induced from the site stabilizer. Again the theorem [1] can be used to find the general form of the hamiltonian, restricting possible theoretical models and enabling further exact simplifications along to these presented in the context of the Dirac-Heisenberg problem.
