Abstract

Background: The torsion of pedunculated uterine leiomyoma is a rare complication of uterine leiomyoma.

Case: A 34-years-old woman was admitted at gynecological emergency for acute pelvic pain. The emergency trans-abdominal ultrasound was in favor of a right ovarian twisted cyst associated with leiomyomas. Laparotomy was performed and showed torsion of pedunculated uterine leiomyoma inserted on the fundus which was removed.

Conclusion: Torsion of a pedunculated uterine leiomyoma is a rare surgical emergency. Imaging should not delay emergency surgery that confirms or sometimes rectifies the diagnosis.

Keywords: Pedunculated uterine leiomyoma; Torsion ultrasound laparotomy; Myomectomy

Introduction

Uterine leiomyoma, a benign tumor of the uterine muscle, is a ubiquitous pathology affecting 20 to 25% of women in reproductive period [1]. Its incidence is 70% at the age of 50 years [2]. It is only symptomatic in 20 to 50% of cases and may have several and various characteristics depending on the number, size and the topography of the leiomyomas [2,3]. Among the multiple complications of the uterine leiomyoma, one is an exceptionnel, the torsion of pedunculated uterine leiomyoma. Its incidence is not well known, only few cases have been described in the literature. It is a surgical emergency whose clinical expression can simulate an adnexial torsion. Imaging can guide the diagnosis. However, laparoscopy or even laparotomy performed in an emergency ensures the management. We report a case of twisted pedunculated uterine leiomyoma discovered during the laparotomy.

Case Report

A 34-years-old woman with no medical history (gravida 0, para 0) was admitted at gynecological emergency for acute pelvic pain appeared 5 days ago. She also complained of three-month bleeding and a lack of improvement of the pelvic pain despite analgesics. The general condition was normal. Physical examination revealed a rounded right painful mass measuring about 10 cm.

The emergency trans-abdominal ultrasound was in favor of a right ovarian twisted cyst which measures 110 mm associated with leiomyomas. Laparotomy rectified the diagnosis by highlighting a necrotic pedunculated uterine leiomyoma that had undergone torsion. The twisted fibroma was 15 cm in diameter (Figure 1).

The annexes were healthy. An uncomplicated myomectomy was performed; the twisted fibroma weighed 3700 grams (Figure 2). The surgical follow-up was uneventful and the discharge was authorized 4 days after the surgery.

Discussion

The torsion of pedunculated uterine leiomyoma is one of the most uncommon surgical emergency [3]. Its symptoms are the same with surgical acute abdomen. This disease imitates different pathologies as the ectopic pregnancy and the adnex twist [4,5].

This torsion occurs only on pedunculated uterine leiomyoma especially if the pedicle is long and thin. The size of the leiomyoma is a key factor in the onset of an irreversible twist. Tsai, in 2006 [6], had reported a case of sub-serosal fibroma measuring 8 cm in diameter. Our patient had a leiomyoma bigger than Tsai's with 15 cm of diameter and 3700 grams.

The torsion of pedunculated leiomyoma is a rare surgical emergency. The clinical expression can simulate a twisted adnex. We must mention it in case of acute pelvic pain especially if the patient is treated for uterine leiomyoma. Abdominal myomectomy by laparotomy remains the treatment of reference.
