(Received July 28, 2020; Accepted June 21, 2021)

We performed an expression analysis of flavonoid-related genes such as chalcone synthase (CHS), chalcone isomerase (CHI), flavanone 3-hydroxylase (F3H), flavonoid 3’-hydroxylase (F3’H), and flavonol synthase (FLS) in order to investigate the effects of light exposure on rutin biosynthesis and to determine the rutin content in green and white asparagus spears (Asparagus officinalis). Gene expression levels for the downstream enzymes in the biosynthesis pathway, i.e., F3H and FLS, were significantly higher in green spears than in white spears; however, no significant difference was observed in the expression of upstream genes, such as CHS, CHI, and F3H. Furthermore, the expression of FLS was the lowest among all flavonoid-related genes, which indicates that it might play an important role in rutin regulation. Rutin remained undetected in white asparagus spears, while green asparagus had relatively high amounts present. The results of this study may explain the molecular basis of the relationship between light exposure and rutin biosynthesis in asparagus spears.

Keywords : Asparagus officinalis L., rutin, flavonol synthase (FLS) gene, light exposure

INTRODUCTION

Asparagus (Asparagus officinalis L.) is one of the most widely produced vegetables in the world. Green and white spears originate from the same cultivar but are produced using different cultivation methods in Japan. White spears are shielded from sunlight, i.e., spears that grow in the absence of light, and green and white spears contain different phytochemicals due to these differences (presence vs. absence of light). Green spears contain rutin, while white spears do not have rutin but are rich in saponin (protodioscin) (Maeda et al., 2005, 2008, 2012). Rutin is one of the most significant flavonoids that has been reported to have biological activities, such as hypertension prevention, anti-inflammatory, anti-tumor, anti-bacterial/viral, and potent radical-scavenging properties. Rutin also has protective effects against capillary fragility and arteriosclerotic vascular changes (Griffith Jr. et al., 1944; Hellerstein et al., 1951; Middleton et al., 2000; Calabro et al., 2005; Guo et al., 2007). Consumer interest in functional foods, such as flavonoids, is increasing; and this interest has been stimulated by the potential health benefits that have arisen from the antioxidant activities of these compounds (Maeda et al., 2006). The main genes involved in rutin biosynthetic pathway are chalcone synthase (CHS), chalcone isomerase (CHI), flavanone-3-hydroxylase (F3H), flavonoid-3’-hydroxylase (F3’H), and flavonol synthase (FLS), glucosyltransferase (GT) and rhamnosyltransferase (RT) (Fig. 1). Studies have revealed that light is one of the most important environmental signals regulating flavonoid biosynthesis (Fuglevand et al., 1996; Jenkins, 1997, 2001; Wade et al., 2001; Maeda et al., 2010; Kopsell and Sams, 2013; Carvalho and Folta, 2014). Supplemental lighting is introduced when asparagus is grown using the “Fusekomi” forcing culture technique, which is a unique cropping technique developed in Japan. With this technique, it was found that the amount of rutin increased as the number of lamps and the duration of light exposure increased, while spear color improved (Wambrauw et al., 2016). Nonetheless, the mechanisms behind this rutin enhancement have not been fully clarified. In addition, only a few studies have addressed the molecular basis of flavonoid metabolism regulation in asparagus (Yi et al., 2019), the effect of light on the accumulation of flavonoid-related genes and the role of light-regulated genes in enhancing rutin production. Therefore, we investigated the effects of light on rutin-related expressions of biosynthetic genes (CHS, CHI, F3H, F3’H, FLS) and the amount of rutin in green (light-exposed) and white (light-shielded) spears.

MATERIALS AND METHODS

Plant material

Two sets of green and white asparagus spear samples were collected for analysis. First, samples cultivated using...
the Fusekomi forcing culture system were collected at Hihosaki University during the winter harvest period. One-year-old rootstocks of UC-157 were dug up from an open field at the Iwate Agricultural Research Center on November 19 and planted in heated cultivating beds (length 1.2 m/width 0.8 m/height 0.45 m for each plot) set up in a greenhouse in the University field on December 6, 2013. Thirty to forty rootstocks were planted in each plot and covered with rice hull compost. Each test plot planted with green asparagus was covered with a plastic tunnel to maintain warmth. Furthermore, to artificially reproduce the poor light conditions typical of winter, the greenhouse was covered with a shading net to reduce incidental sunlight.

White asparagus is usually produced using the film-cover method (Maeda et al., 2005, 2012); thus, the test plot was covered with a sun-blocking film (Tokan white silver, Tokankosan Co., Japan). The minimum air temperature was kept >10°C using an oil heater, and the soil temperature was kept at approximately 18°C using heating wires. The trial was conducted from January 14 to February 24, 2014. During the 6-week harvest period, only samples harvested on February 17 and 24, 2014, were used for subsequent analysis. Only spears grown under natural light without supplemental lighting were used for subsequent analysis. Green and white spears were harvested after reaching 27 cm in length and were then cut down to 24 cm.

---

**Fig. 1**  Schematic of flavonoid biosynthesis in asparagus. Two general classes of the end product are found in asparagus: flavonols (rutin: quercetin-3-O-rutinoside) and anthocyanins. Enzymes are indicated in bold. CHS: chalcone synthase (CHS catalyzes the first committed step in this pathway), CHI: chalcone isomerase, F3H: flavanone synthase, F3’H: flavanone 3′-hydroxylase, DFR: dihydroflavonol 4-reductase, FLS: flavonol synthase, GT: glucosyltransferase, RT: rhamnosyl transferase. Genes marked with * were examined in the present study.
for testing. The second set of asparagus samples were collected from Farm Horo, Shin Hidaka-Cho, Hokkaido, Japan. Green and white spears were harvested during the spring harvest season from 4-year-old UC-157 cultivars. The sample spears were harvested from greenhouses during the latter half of June 2016 and were immediately packed and sent to Hirosaki University for analysis. White spears were produced by covering the greenhouse with a sun-blocking film (Tokan white silver, Tokankosan Co., Japan).

Sample preparation for analysis of gene expression and rutin content
Three to four middle- (M; 13–18 g) to large-sized (L; 18–23 g) spears of green and white asparagus were cut into three equal sections (each section 8 cm in length). Only the sections with spearheads were evaluated for gene expression analysis and rutin content because rutin content has been reported to be highest in the spearheads (Chin et al., 2002, Maeda et al., 2008). The samples were then vertically cut in half; one half was used for RNA extraction while the other was immediately frozen and then lyophilized to determine rutin content. Total RNA was extracted from about 50–100 mg of epidermal tissue collected from the samples using an RNAasy Plant Mini Kit (QIAGEN, USA). The cDNA was reverse transcribed from 1 μg of the extracted RNA using a QuantiTech Reverse Transcription Kit (QIAGEN, USA). The cDNA samples were stored at −18°C. HPLC analysis was performed. Rutin was extracted from 20 mg of the freeze-dried powder obtained from each set of samples using 1 mL 80% methanol, and the extraction was conducted for 3 hours at room temperature. Sample solutions were then centrifuged (10,000 rpm, 10 minutes), and the supernatants were used for further analysis.

Determination of rutin content using HPLC
Rutin content was determined using high-performance liquid chromatography (HPLC) as described by Maeda et al. (2012). This analysis was conducted using a Waters Sunfire C18 (4.6×250 mm) column. The mobile phases consisted of 0.1% trifluoroacetic acid (solvent A) and acetonitrile (solvent B). Chromatographic separation was performed by running each sample for 30 minutes at a column temperature of 40°C, using a linear gradient system at a flow rate of 1.0 mL min⁻¹. Each run was monitored at a wavelength of 354 nm via the UV detectors. The gradient was maintained as follows: 0 minutes, 84% solvent A and 16% solvent B; 20 minutes, 60% solvent A and 40% solvent B; 30 minutes, 40% solvent A and 60% solvent B, and the post-running time was 10 minutes. Rutin content was calculated using a standard external method with a calibration curve prepared by analyzing the data from rutin standard solutions with concentrations of 0.100, and 250 ppm (Wako Chemical Co., Japan).

RESULTS AND DISCUSSION
In the present study, a comparative analysis of flavonoid-related genes and rutin content in green and white spears was performed to investigate how light influences the regulation of rutin. In the first set of samples, the relative gene expression of CHS and CHI—from the first and second gene in the flavonoid biosynthetic pathway (Fig. 2), followed by F3H—did not differ significantly between green and white spears (Fig. 3). F3H expression was significantly higher in green spears than in white spears. The relative gene expression of FLS was also significantly higher in green spears than in white spears (Fig. 3). The CHS, CHI, and F3H expression patterns in the second set of samples (harvested from Farm Horo) were found to be similar to the first samples (data not shown). However, the expression of the downstream genes, especially FLS, was significantly higher in green spears than in white spears (Fig. 4). The genes that function in the upstream flavonoid biosynthesis pathway were expressed in unpigmented white spears, and their relative gene expression levels were similar to those in green spears. A similar study reported that all flavonoid-related genes were expressed in unpigmented white grapes (Boss et al., 1996). All these genes are precursors for the next genes in the biosynthesis path-
Fig. 2 Expression levels of the earliest genes in the flavonoid biosynthesis pathway. CHS: chalcone synthase, CHI: chalcone isomerase. Green spears were grown under natural light, while white spears were grown under dark conditions. Both green and white spears were harvested during the winter period using the Fusekomi forcing culture system at Hirosaki University. Bars indicate SD. Statistical analysis of the data was performed using t-tests (n = 3).

Fig. 3 Expression levels of genes that function in the downstream process of the flavonoid biosynthesis pathway. F3H: flavanone 3-hydroxylase, F3'5'H: flavonoid 3',5'-monooxygenase, FLS: flavonol synthase. Green spears were grown under natural light while white spears were grown under dark conditions. Both green and white spears were harvested during the winter period using the Fusekomi forcing culture system at Hirosaki University. Bars indicate SD. Statistical analysis of the data was performed using t-tests. * indicate significant differences (P < 0.05, n = 3).

Fig. 4 Expression levels of the last genes in the flavonoid biosynthesis pathway. F3'5'H: flavonoid 3',5'-monooxygenase, FLS: flavonol synthase. Green spears were grown under natural light, while white spears were grown under dark conditions. Statistical analysis of the data was performed using t-tests. * indicate significant differences (P < 0.05, n = 3).
way, which may explain why the expression of these genes occurs in the absence of rutin in unpigmented white spears (Fig. 5). Although all flavonoid-related genes were detected in white spears, the expression levels of F3'H and FLS were significantly lower in white spears than green spears. The expression of FLS in both the first and second sets of samples was lower than that of F3'H; it was even quite low in green spears. These results indicated that the expression of FLS was reduced to nearly zero with the absence of light, while FLS expression levels significantly increased in the presence of light (green spears). Since we did not measure the activities of each enzyme, we cannot determine which enzyme is the most important for flavonoid biosynthesis in asparagus spears. However, the results of this study suggest that FLS is an important enzyme that strongly responds to light. FLS is known to be a catalyst that converts dihydroquercetin to quercetin, which is the starting point of flavonols and also rutin biosynthesis. Our results indicate that light enhances light exposure and the expression of flavonoid-related genes in asparagus. Our results indicate that light enhances light exposure and the expression of flavonoid-related genes in asparagus. Our results indicate that light enhances light exposure and the expression of flavonoid-related genes in asparagus.

Fig. 5 Rutin content in green and white spears. Green spears were grown under natural light, while white spears were grown under dark conditions. Bars indicate SD (n = 12). ND: not detected.

In this study, we investigated the relationship between light exposure and the expression of flavonoid-related genes in asparagus. Our results indicate that light enhances rutin biosynthesis and that FLS plays an important role in the response of asparagus spears to light.
