ON THE AFFINE SCHÜTZENBERGER INVOLUTION

DONGKWAN KIM

Abstract. We consider an involution on the affine Weyl group of type $A$ induced from the nontrivial automorphism on the (finite) Dynkin diagram. We prove that the number of left cells fixed by this involution in each two-sided cell is given by a certain Green polynomial of type $A$ evaluated at $-1$.

1. Introduction

This paper is motivated by a paper of Lusztig [Lus83a]. Let $W$ be the Weyl group of type $A_{n-1}$ and $\tilde{W}$ be the centralizer of the longest element in $W$. Then $\tilde{W}$ is naturally the Weyl group of type $C_m$ where $m = \lceil n/2 \rceil$. If $L : \tilde{W} \to \mathbb{N}$ is the restriction of the usual length function $l : W \to \mathbb{N}$, then [Lus83a] gives a description of left cells in $\tilde{W}$ with the weight function $L$, and showed that each left cell carries an irreducible representation of $\tilde{W}$.

One of our goals in this paper is to extend his method to an affine setting. Let $W_a$ be the affine Weyl group of type $A_{n-1}$ and let $\omega$ be the involution of $W_a$ which corresponds to the nontrivial automorphism of the (finite) Dynkin diagram of type $A$. Then, the main theorem in this paper states that the number of left cells fixed by $\omega$ in each two-sided cell of $W_a$ is given by a certain Green polynomial of type $A$, originally defined by Green [Gre55], evaluated at $-1$.

This paper is considered as a sibling of [CFKLY]. There exists a bijection defined by Shi [Shi86, Shi91] between left cells of $W_a$ and row-standard Young tableaux, called the generalized Robinson-Schensted correspondence. Under this bijection, the involution $\omega$ corresponds to an affine analogue of the usual Schützenberger involution. The combinatorics of this involution is extensively studied in [CFKLY], and our main theorem also follows from a more general result therein. Here, instead we explain this involution $\omega$ in a representation-theoretic view, and also provide another proof of our main theorem in terms of representation theory.

This paper is organized as follows: in Section 2 we cover basic notations and definitions used in this paper; in Section 3 we define and describe the involution $\omega$, called the affine Schützenberger
involution; in Section 4 we state the main theorem of this paper and remark some related facts; in Section 5 we prove the main theorem modulo some combinatorial reduction; in Section 6 we introduce an combinatorial model associated with our main objects and complete the proof of the main theorem.

Acknowledgement. The author thanks Roman Bezrukavnikov for kindly explaining his theory to him; it would have been impossible to write this paper without his help. The author is indebted to Michael Chmutov, Gabriel Frieden, and Joel Brewster Lewis for discussions about combinatorial descriptions of this subject, including contents in Section 6. He also thanks Sam Hopkins for making such discussions possible. Finally, he is grateful to George Lusztig for his helpful comments.

2. Notations and definitions

2.1. Basic notations. For a set $X$, we define $|X|$ to be the cardinal of $X$. If there is a map $f : X \to X$, we denote by $X^f$ the set of elements in $X$ fixed by $f$. Similarly, if there exists a group $G$ acting on $X$, then we denote by $X^G$ the set of elements in $X$ fixed by the action of $G$.

For a variety $X$, we denote by $H^i_p(X) = H^i_p(X, \mathbb{Q}_l)$ its $i$-th $\ell$-adic cohomology group, and define $H^*(X) := \bigoplus_{i \in \mathbb{Z}} (-1)^i H^i_p(X)$ to be their alternating sum (as a virtual $\mathbb{Q}_l$-vector space).

For an abelian category $C$, we write $D^b_pC$ to be its bounded derived category, and $K^pC := K_pC$ to be the complexified Grothendieck group of $C$. Likewise, for a variety $X$, we write $K^pX := K_pX$ to be the complexified $K$-theory of $X$, i.e. the complexified Grothendieck group of the category of coherent sheaves on $X$. If there is an action of a group $G$ on $X$, then we denote by $K^G_pX := K^p(X)_C$ the complexified $G$-equivariant $K$-theory of $X$.

2.2. General setup. We fix $n \in \mathbb{Z}_{\geq 0}$ throughout this paper. Let $G := GL_n$ be the general linear group of rank $n$ defined over $\mathbb{C}$, $B \subset G$ be the Borel subgroup consisting of upper-triangular matrices, and $T \subset B$ be the maximal torus consisting of diagonal matrices. Also let $\mathfrak{g} := \text{Lie } G$, $\mathfrak{b} := \text{Lie } B$, and $\mathfrak{h} := \text{Lie } T$ be corresponding Lie algebras. Define $B := G/B$ to be the flag variety of $G$. For a nilpotent element $N \in \mathfrak{g}$, let $B_N$ be the Springer fiber of $N$, defined by $B_N := \{ gB \in B \mid \text{Ad}(g)^{-1}(N) \in \mathfrak{b} \}$.

2.3. Weyl groups of $G$. Let $W$ and $\tilde{W}$ be the Weyl group and the extended affine Weyl group of $G$, respectively. They are defined as follows.

$$W := N(G,T)/T, \quad \tilde{W} := N(G_{\mathbb{C}(t)}(t), T_{\mathbb{C}(t)}(t))/T_{\mathbb{C}(t)[t]}.$$ Here, $N(X,Y)$ denotes the normalizer of $Y$ in $X$, and $G_R$ (resp. $T_R$) is the base change of $G$ (resp. $T$) from $\mathbb{C}$ to $R$. Also, we define $W_a \subset \tilde{W}$ to be the subgroup generated by elements in $N(G_{\mathbb{C}(t)}(t), T_{\mathbb{C}(t)}(t))$ whose determinant is contained in $\mathbb{C}[[t]]^*$, called the affine Weyl group of $G$. Then, $W$ is naturally a subgroup of $W_a$. 
We choose \( \{s_1, \ldots, s_{n-1}\} \subset W \) such that \( s_i \) corresponds to swapping \( i \)-th and \( (i+1) \)-th entries of diagonal matrices. Also we let \( s_0, \tau \in \tilde{W} \) be the images of

\[
\begin{pmatrix}
0 & 0 & 0 & \cdots & 0 & 0 & t \\
0 & 1 & 0 & \cdots & 0 & 0 & 0 \\
0 & 0 & 1 & \cdots & 0 & 0 & 0 \\
\cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
0 & 0 & 0 & \cdots & 1 & 0 & 0 \\
0 & 0 & 0 & \cdots & 0 & 1 & 0 \\
\tau^{-1} & 0 & 0 & \cdots & 0 & 0 & 0
\end{pmatrix}
\]

and

\[
\begin{pmatrix}
0 & 0 & 0 & \cdots & 0 & 0 & t \\
1 & 0 & 0 & \cdots & 0 & 0 & 0 \\
0 & 1 & 0 & \cdots & 0 & 0 & 0 \\
\cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
0 & 0 & 0 & \cdots & 1 & 0 & 0 \\
0 & 0 & 0 & \cdots & 0 & 1 & 0 \\
\tau^{-1} & 0 & 0 & \cdots & 0 & 0 & 0
\end{pmatrix}
\]

respectively. Then,

- \( (W, \{s_1, \ldots, s_{n-1}\}) \) and \( (W_a, \{s_0, s_1, \ldots, s_{n-1}\}) \) are Coxeter groups,
- \( \tau s_i \tau^{-1} = s_{i+1} \) for \( 0 \leq i \leq n-2 \) and \( \tau s_{n-1} \tau^{-1} = s_0 \), and
- \( \tilde{W} \cong W_a \rtimes \langle \tau \rangle \), \( \langle \tau \rangle \cong \mathbb{Z} \).

We define \( S := \{s_0, s_1, \ldots, s_{n-1}\} \) to be the set of simple reflections of \( W_a \).

2.4. Involution \( \omega \). Define \( J \in G \) to be the matrix whose anti-diagonal entries are 1 and other entries are 0. We define an involutive automorphism \( \omega \) on \( G \) by

\[
\omega : G \mapsto G : g \mapsto J(g^{-1})J^{-1}.
\]

We abuse notation and write \( \omega \) for an involution on any object which is naturally induced from the above automorphism. Clearly, it induces an involution on \( g \) defined by \( \omega(X) = -\text{Ad}(J)(t^{-1}X) \). Also, it induces involutions on \( W, W_a, \) and \( \tilde{W} \), respectively. Indeed, direct calculation shows that

\[
\omega(s_i) = s_{n-i} \text{ for } 1 \leq i \leq n-1, \quad \omega(s_0) = s_0, \quad \omega(\tau) = \tau^{-1}.
\]

On the other hand, since \( \omega \) fixes \( B \), it defines an action on the flag variety of \( G \). If \( N \in g \) is a nilpotent element fixed by \( \omega \), then \( \omega \) acts on its Springer fiber \( B_N \) and thus acts on the cohomology and the \( K \)-theory of \( B_N \) as well.

2.5. Kazhdan-Lusztig cells. We usually use the symbol \( \underline{c} \) (resp. \( \Gamma, \Gamma^{-1} \)) to denote a two-sided (resp. left, right) cell of \( \tilde{W} \). (The notion of Kazhdan-Lusztig cells is first defined in [KL79] for Coxeter groups, and is generalized to extended affine Weyl groups in [Lus89].) Then each two-sided (resp. left, right) cell of \( W_a \) is of the form \( \underline{c} \cap W_a \) (resp. \( \Gamma \cap W_a, \Gamma^{-1} \cap W_a \)), and this gives a bijection between two-sided (resp. left, right) cells of \( W_a \) and \( \tilde{W} \). Note that each two-sided (resp. left, right) cell of \( \tilde{W} \) is stable under multiplication (resp. left multiplication, right multiplication) by \( \tau \in \tilde{W} \).

In [Lus89], a canonical bijection between two-sided cells of \( \tilde{W} \) and nilpotent orbits in \( g \) is constructed. (Here, we identify \( g \) with its Langlands dual.) We write \( \underline{a} \lambda \) to be the two-sided cell that corresponds to the nilpotent orbit in \( g \) of Jordan type \( \lambda \vdash n \) under this bijection. Then \( a(\underline{a} \lambda) \) is equal to the dimension of the Springer fiber corresponding to this nilpotent orbit, where \( a \) is Lusztig’s \( a \)-function defined in [Lus85].
2.6. Partitions, tableaux, and tabloids. For a partition \( \lambda \), we write \( \lambda = (\lambda_1, \ldots, \lambda_r) \) for \( \lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_r > 0 \) or \( \lambda = (1^{m_1}2^{m_2}\cdots) \) to describe its parts. Let \( l(\lambda) \) be the length of \( \lambda \), and put \( \lambda_i = 0 \) if \( i > l(\lambda) \). Define \( |\lambda| := \sum_{i > 1} \lambda_i = \sum_{i > 1} m_i \). If \( |\lambda| = k \), we also write \( \lambda \vdash k \). We say \( \lambda \) is strict if \( \lambda_1 > \lambda_2 > \cdots > \lambda_r > 0 \), or equivalently each \( m_i \) is either 0 or 1. For another partition \( \mu \), we write \( \lambda \vdash \mu \) to be the partition of \( |\lambda| + |\mu| \) whose parts are the union (as a multiset) of parts of \( \lambda \) and \( \mu \).

For a partition \( \lambda \), define \( SYT(\lambda) \) to be the set of standard Young tableaux of shape \( \lambda \) with entries 1, 2, \ldots, \( |\lambda| \). Similarly, we define \( RSYT(\lambda) \) to be the set of row-standard Young tableaux of shape \( \lambda \) with entries 1, 2, \ldots, \( |\lambda| \), which is defined by dropping the condition from \( SYT(\lambda) \) that each column is strictly increasing. If \( \lambda \) is a finite sequence of positive integers which is not necessarily a partition, we still write \( RSYT(\lambda) \) to denote the set of row-standard Young tabloids of shape \( \lambda \). For a tabloid \( T \), we write \( T \vdash p \) to be the partition \( |T| \) of each part of \( T \).

3. The affine Schützenberger involution

The involution \( \omega \) on \( G \) induces an involution on \( \tilde{W} \), which also permutes Kazhdan-Lusztig cells of \( \tilde{W} \).

Definition 3.1. The affine Schützenberger involution is the involution induced by \( \omega \) on the set of left cells of \( \tilde{W} \), again denoted by \( \omega \).

If we restrict \( \omega \) to the Coxeter group \( (W, S - \{s_0\}) \), then it corresponds to the nontrivial involutive automorphism on the Dynkin diagram of type \( A \), which is the same as conjugation by the longest element of \( W \). This involution clearly permutes the left cells of \( W \), and it is equivalent to the usual Schützenberger involution on standard Young tableaux under the Robinson-Schensted correspondence. This is why we call \( \omega \) the affine Schützenberger involution.

Note that the usual Schützenberger involution preserves the shape of each standard Young tableau. It means that the corresponding involution on \( W \) stabilizes each two-sided cell of \( W \). The same is true for \( \omega \), as the following lemma shows.

Lemma 3.2. Suppose that \( \underline{\xi} \) is a two-sided cell of \( \tilde{W} \). Then \( \omega(\underline{\xi}) = \underline{\xi} \).

Proof. It is clear that \( \omega(\underline{\xi}) \) is also a two-sided cell of \( \tilde{W} \). Recall that \( \underline{\xi} \) is stable under multiplication by \( \tau \), thus in particular under its conjugation. Thus by [Lus89, Theorem 4.8(d)], \( \underline{\xi} \) intersects nontrivially with \( W \). As we observed already that \( \omega \) stabilizes each two-sided cell of \( W \), the result follows. \( \square \)

Therefore, it is possible to restrict \( \omega \) to each two-sided cell of \( \tilde{W} \). We are interested in the number of left cells in each two-sided cell that are fixed by \( \omega \).
4. Main theorem and some remarks

4.1. Statement of the main theorem. For \( k \in \mathbb{N} \), let \( \rho_2(k) \) be the partition \((2, 2, \ldots, 2) \vdash k\) (resp. \((2, 2, \ldots, 2, 1) \vdash k\)) if \( k \) is even (resp. odd). The main result of this paper is as follows.

**Theorem 4.1** (Main theorem). *Suppose that a two-sided cell \( \z \subseteq \widehat{W} \) corresponds to the partition \( \lambda \vdash n \). Then the number of left cells in \( \z \) that are fixed by \( \omega \) is given by \( Q^\lambda_{\rho_2(n)}(-1) \), where \( Q^\lambda_{\rho_2(n)}(t) \) is the Green polynomial (for type A) originally defined in [Gre55].*

It follows from a more general result in [CFKLY] which is proved in terms of combinatorics. In this paper we give another proof of this theorem using representation theory.

4.2. Affine Weyl groups of type \( C \). Let \( \widehat{W}_a \) be the set of elements in \( W_a \) fixed by \( \omega \) and \( L \) be the restriction of \( l : W_a \rightarrow \mathbb{N} \) to \( W_a \). Then \( \widehat{W}_a \) is the affine Weyl group of type \( C \), and the pair \((\widehat{W}_a, L)\) is said to be in the quasisplit case in the sense of [Lus14]. There exists a strong connection between cells in \( W_a \) and \((\widehat{W}_a, L)\) as the following lemma shows.

**Lemma 4.2.** *Suppose that \( \z \) (resp. \( \Gamma \)) is a two-sided (resp. left) cell of \( \widehat{W} \). Thus \( \z \cap W_a \) (resp. \( \Gamma \cap W_a \)) is a two-sided (resp. left) cell of \( W_a \).

1. \( \Gamma \cap \widehat{W}_a \) is nonempty if and only if \( \Gamma \) is stable under \( \omega \).
2. If \( \Gamma \cap \widehat{W}_a \) is nonempty, then it is also a left cell of \((\widehat{W}_a, L)\).
3. \( \z \) is always \( \omega \)-stable, and \( \z \cap \widehat{W}_a \) is a (nonempty) union of two-sided cells of \((\widehat{W}_a, L)\).

*Proof.* For (a), one direction is clear since \((W_a)^\omega = \widehat{W}_a\). For the other direction, first note that there exists \( D \subset W_a \) (the set of Duflo involutions), such that \( \omega(D) = D \) and \( D \cap \Gamma \) consists of only one element for each \( \Gamma \). Therefore, if \( \omega(\Gamma) = \Gamma \) then the unique element \( D \cap \Gamma \) is fixed by \( \omega \), thus \( \Gamma \cap \widehat{W}_a \) is nonempty.

For (b), we rely on the results of [Lus14]. Since \( W_a \) is tame (see [Lus14, 1.11, 1.15]), it is bounded in the sense of [Lus14, 13.2] (also see [Lus14, 13.4] and [Lus85, Theorem 7.2] for its proof). Therefore, the argument in [Lus14, Chapter 16] is applicable and (b) follows from [Lus14, Lemma 16.21].

For (c), the first part is exactly Lemma 4.2. To show that \( \z \cap \widehat{W}_a \) is nonempty, we consider the canonical left cell \( \z \subseteq \widehat{W}_a \) defined in [LX88]. Then clearly \( \Gamma \) is \( \omega \)-stable, thus \( \z \cap \widehat{W}_a \supseteq \Gamma \cap \widehat{W}_a \) is nonempty by (a). Finally, \( \z \cap \widehat{W}_a \) is a union of two-sided cells of \((\widehat{W}_a, L)\) by [Lus14, Lemma 16.20(b)] (and its right analogue). \( \square \)

**Remark.** In general, \( \z \cap \widehat{W}_a \) is not a single two-sided cell. For example, if \( n = 4 \) and \( m = 2 \), there are 6 two-sided cells in \((W_a, L)\), but \( \widehat{W} \) has only 5 two-sided cells. Indeed, the second highest two-sided cell of \( \widehat{W} \) (which contains \( S \)) splits into two two-sided cells \( \{s_0\}, \{s_2\} \) of \( \widehat{W}_a \). (ref. [Gui08, p.40])

Now the following corollary is an immediate consequence.

**Corollary 4.3.** *Let \( \z \) be a two-sided cell of \( \widehat{W} \). Then the number of left cells of \((\widehat{W}_a, L)\) in \( \z \cap \widehat{W}_a \) is equal to the number of left cells of \( \widehat{W} \) in \( \z \) fixed by the involution \( \omega \).*
4.3. Relation to Domino tableaux and Springer theory. Let \( \check{G} \) be \( SO_n \) (resp. \( Sp_n \)) over \( \mathbb{C} \) if \( n \) is odd (resp. even) and \( \mathfrak{g} \) be its Lie algebra. Regard \( \check{W} := W^\omega \) as the Weyl group of \( \check{G} \) in a natural way. For a nilpotent element \( \check{N} \in \mathfrak{g} \), let \( A_{\check{N}} \) be the component group of the stabilizer of \( \check{N} \) in \( \check{G} \). Let \( \check{B} \) be the flag variety of \( \check{G} \) and \( \check{B}_{\check{N}} \) be the Springer fiber of \( \check{N} \).

There exists a canonical bijection between two-sided cells in \( \check{W} \) (with equal parameters) and special nilpotent orbits in \( \mathfrak{g} \). Pick a two-sided cell \( \check{\mathfrak{c}} \subset \check{W} \) and let \( \check{N} \in \mathfrak{g} \) be the nilpotent element in the corresponding special nilpotent orbit. Also let \( \lambda \) be the Jordan type of \( \check{N} \). Then it follows from the results of Barbasch-Vogan [BV82] and Garfinkle [Gar90, Gar92, Gar93] that the number of left cells in \( \check{\mathfrak{c}} \) is equal to that of standard domino tableaux of shape \( \lambda \). It is also the same as the number of \( A_{\check{N}} \)-orbits in the set of irreducible components of \( \check{B}_{\check{N}} \), see [McG99, McG00].

This statement has an “unequal” analogue as follows. If we restrict \( L : \check{W}_a \to \mathbb{N} \) to \( \check{W} \), then again \( (\check{W}, L|_{\check{W}}) \) is in the quasisplit case in the sense of [Lus14]. Thus similarly to the affine case above, the left cells of \( (\check{W}, L|_{\check{W}}) \) are precisely an intersection of \( \check{W} \) and some left cell of \( \check{W} \) fixed by \( \omega \) (see [Lus83a]). For a partition \( \lambda \vdash n \), let \( \check{\mathfrak{c}}_\lambda \subset \check{W} \) be the two-sided cell of \( \check{W} \) parametrized by \( \lambda \). Then the number of left cells of \( (\check{W}, L|_{\check{W}}) \) contained in \( \check{\mathfrak{c}}_\lambda \cap \check{W} \) is equal to the number of standard domino tableaux of shape \( \lambda \). In particular, if \( \lambda \) is the Jordan type of a nilpotent element \( \check{N} \in \mathfrak{g} \) (not necessarily special), then it is again the same as the number of \( A_{\check{N}} \)-orbits in the set of irreducible components of \( \check{B}_{\check{N}} \).

The statement above also has an “affine” analogue. For simplicity, let us assume that \( n \) is odd, thus \( \check{G} = SO_n \) is of type \( B \). Then \( \check{W}_a \) is naturally the affine Weyl group of the Langlands dual of \( \check{G} \). There exists a canonical bijection between nilpotent orbits in \( \mathfrak{g} \) and two-sided cells of \( \check{W}_a \) (with equal parameters) defined in [Lus89]. Pick a two-sided cell \( \check{\mathfrak{c}} \subset \check{W}_a \) and let \( \check{N} \in \mathfrak{g} \) be a nilpotent element in the corresponding nilpotent orbit. Then, a weaker version of [Lus89, Conjecture 10.5], proved in [Bez04, BO04, BFO09], implies that the number of left cells in \( \check{\mathfrak{c}} \) is given by the dimension of \( (H^*(\check{B}_{\check{N}}))^A_{\check{N}} \).

The main theorem in this paper should be considered as an “affine unequal” analogue of the first statement. Again let \( G \) be \( SO_n \) or \( Sp_n \) depending on the parity of \( n \), and let \( \check{N} \in \mathfrak{g} \) be a nilpotent element of Jordan type \( \lambda \vdash n \). Let \( \check{\mathfrak{c}}_\lambda \subset \check{W} \) be the two-sided cell of \( \check{W} \) parametrized by \( \lambda \). Then the result of [Kim17] together with Theorem 4.1 implies that the number of left cells of \( (\check{W}_a, L) \) contained in \( \check{\mathfrak{c}}_\lambda \cap \check{W}_a \) is equal to the Euler characteristic of \( \check{B}_{\check{N}} \), i.e. the dimension of \( H^*(\check{B}_{\check{N}}) \).

5. Proof of the main theorem

5.1. Reduction to strict partitions. First, we claim that in order to prove the main theorem it suffices only to consider the case when a two-sided cell \( \check{\mathfrak{c}} \subset \check{W} \) corresponds to a strict partition. This follows from two propositions below.

Proposition 5.1. Suppose that \( \lambda = (\lambda_1, \ldots, \lambda_r) \vdash n-2k \) is a partition for some \( k \geq 1 \). Let \( \varphi(\lambda \cup (k, k)) \) be the number of left cells in \( \check{\mathfrak{c}}_{\lambda \cup (k, k)} \) fixed by \( \omega \). We define \( \varphi(\lambda) \) similarly (by replacing \( n \) with \( n-2k \), etc.) Then, for \( m = \lfloor n/2 \rfloor \) we have

\[
\varphi(\lambda \cup (k, k)) = \binom{m}{k} 2^k \varphi(\lambda).
\]
Its proof relies on combinatorics, which we postpone until Section 6. We refer readers to \cite{CKLY} for detailed combinatorial descriptions of the affine Schützenberger involution.

**Proposition 5.2.** Suppose that $\lambda = (\lambda_1, \ldots, \lambda_r) \vdash n - 2k$ is a partition for some $k \geq 1$. Then,

$$Q_{\rho_2(n)}^{\lambda \cup (k,k)}(-1) = \binom{m}{k} 2^k Q_{\rho_2(n-2k)}^{\lambda}(1)$$

where $m = \lfloor n/2 \rfloor$ and $Q_{\rho_2(n)}^{\lambda \cup (k,k)}(t)$, $Q_{\rho_2(n-2k)}^\lambda(t)$ are the corresponding Green polynomials.

**Proof.** Let $Q'_\lambda(t)$ be the modified Hall-Littlewood $Q'$-function. (See [Kir98] for its definition and properties.) Note that $Q'_\lambda(t) = t^{b(\lambda)} \sum_{\rho} z_\rho^{-1} Q_\rho^\lambda(t^{-1}) p_\rho$ where $b(\lambda) = \sum_{i \geq 1} (i-1) \lambda_i$, $z_\rho = \prod_{i \geq 1} i^{m_i} m_i$ for $\rho = (1^{m_1} 2^{m_2} \cdots)$, and $p_\rho$ is a power symmetric function. Thus we have

$$\langle Q'_{\lambda \cup (k,k)}(-1), p_{\rho_2(n)} \rangle = (-1)^{b(\lambda \cup (k,k))} Q_{\rho_2(n)}^{\lambda \cup (k,k)}(-1) = (-1)^{b(\lambda) + k} Q_{\rho_2(n)}^{\lambda \cup (k,k)}(-1)$$

where $\langle \ , \ \rangle$ is the usual scalar product on the ring of symmetric functions.

On the other hand, by [LLT94] Theorem 2.1 and 2.2 we have $Q'_\lambda(-1) = (-1)^k Q'_\lambda(-1) s_k[p_2]$, where $s_k$ is the Schur function corresponding to the partition $(k)$, $p_2$ is the power symmetric function corresponding to (2), and $s_k[p_2]$ is their plethysm. Therefore, $\langle Q'_{\lambda \cup (k,k)}(-1), p_{\rho_2(n)} \rangle$ is also equal to (here we use orthogonality of power symmetric functions with respect to $\langle \ , \ \rangle$)

$$(-1)^k \langle Q'_\lambda(-1) s_k[p_2], p_{\rho_2(n)} \rangle = (-1)^{b(\lambda) + k} Q_{\rho_2(n-2k)}^\lambda(-1)$$

$$\frac{z_{\rho_2(n-2k)}^{-1}}{z_{\rho_2(n-2k)}^{-1}} \langle p_{\rho_2(n-2k)} s_k[p_2], p_{\rho_2(n)} \rangle$$

$$= (-1)^{b(\lambda) + k} Q_{\rho_2(n-2k)}^\lambda(-1)$$

$$\frac{z_{\rho_2(n-2k)}^{-1}}{z_{\rho_2(n-2k)}^{-1}} \langle p_{\rho_2(n)} p_{\rho_2(n)} \rangle$$

$$= (-1)^{b(\lambda) + k} Q_{\rho_2(n-2k)}^\lambda(-1)$$

$$\frac{m! 2^k}{(m-k)! k!} Q_{\rho_2(n-2k)}^\lambda(-1).$$

Hence the result follows. \hfill $\square$

Combining two propositions above, we see that if the main theorem is true for $Q'_\lambda$, then it is also true for $Q_{\lambda \cup (k,k)}$. Thus by inductive argument, the main theorem is valid if and only if it is valid for strict partitions.

**Remark.** We believe that this part is not essential to the proof of the main theorem; it is likely that argument in Section 5.2 can be applied to the general cases without assuming that the corresponding partition is strict. However, this assumption is still useful as it simplifies our proof.

### 5.2. Asymptotic Hecke algebra and the canonical basis of $K(\mathcal{B}_\lambda)$. From now on, we fix a two-sided cell $\underline{c} = \underline{c}_\lambda \subset \widehat{W}$ where $\lambda$ is strict. Let $N \in \mathfrak{g}$ be a nilpotent element of Jordan type $\lambda$. By [Car93] p.398, the reductive part of $Z_G(N)$ (the stabilizer of $N$ in $G$) is a torus isomorphic to $(\mathbb{C}^*)^{\ell(\lambda)}$, which we denote by $F_{\underline{c}}$. The idea we pursue here is motivated by the conjecture of Lusztig relating the asymptotic Hecke algebra $\mathcal{H}_\lambda$ attached to $\underline{c}$ and the $F_{\underline{c}}$-equivariant $K$-theory of a certain finite set, see [Lus89], Conjecture 10.5].
We recall some results of [Bez16]. Let $D_{P^{\mu}}$ be the category defined in [Bez16] p.4 and $P_{P^{\mu}}$ be its subcategory of perverse sheaves. Also, define $\mathfrak{g} := \{(X, gB) \in g \times B \mid Ad(g)^{-1}X \in B\}$ equipped with the obvious projection $\mathfrak{g} \to g$. Then we have a natural equivalence of categories [Bez16][Theorem 1]

$$D_{P^{\mu}} \simeq D^b(P_{P^{\mu}}) \simeq D^b(Coh^G_N(\mathfrak{g} \times g \hat{g} \hat{g})),$$

where $Coh^G_N(\mathfrak{g} \times g \hat{g} \hat{g})$ is the category of $G$-equivariant coherent sheaves which are set-theoretically supported on the nilpotent cone $N \subset g$. (Here we identify $G$ with its Langlands dual.) This isomorphism respects the convolution structure on both sides.

Following [Bez16] 11.2, it induces a canonical isomorphism

$$D_{P^{\mu}} \simeq D^b(A \otimes_{\mathcal{O}(g)} A - mod^G_N),$$

where $A \otimes_{\mathcal{O}(g)} A$ is a subcategory of $\mathcal{O}(g)$-$A$-modules that are set-theoretically supported on $N \subset \mathfrak{g}$. Here, $\mathcal{O}(g)$ is the coordinate ring of $\mathfrak{g}$ and $A$ is a non-commutative Grothendieck resolution of $\mathfrak{g}$ with the obvious projection $\mathfrak{g} \to g$. (See also [Bez00].)

Recall the bijection between two-sided cells and nilpotent orbits in $\mathfrak{g}$ in [Lus89]. This bijection is order-preserving [Bez99], and each order induces a filtration on each of two categories above. More precisely, let $D_{P^{\mu}}_{<w}$ (resp. $D_{P^{\mu}} = D_{P^{\mu}}<w \leq \ell$) be the thick subcategory of $D_{P^{\mu}}$ generated by irreducible objects $IC_{w} \in P_{P^{\mu}}$ for $w \in \ell \leq \ell'$ (resp. $w \in \ell < \ell'$), where $IC_{w}$ is defined as in [Bez16][Theorem 55]. Then the quotient $D_{P^{\mu}}_{<w}/D_{P^{\mu}}_{<w}$, denoted $D_{P^{\mu},c}$, is well-defined. Likewise, for a nilpotent orbit $\mathfrak{O} \subset \mathfrak{g}$ let $D^b(A \otimes_{\mathcal{O}(g)} A - mod^G_{\mathcal{O}})$ (resp. $D^b(A \otimes_{\mathcal{O}(g)} A - mod^G_{\mathcal{O}})$) be the full subcategory of $D^b(A \otimes_{\mathcal{O}(g)} A - mod^G_{\mathcal{O}})$ consisting of complexes whose cohomology is set-theoretically supported on $\mathcal{O}$ (resp. $\mathcal{O} - \mathcal{O}$). Then the quotient $D^b(A \otimes_{\mathcal{O}(g)} A - mod^G_{\mathcal{O}})/D^b(A \otimes_{\mathcal{O}(g)} A - mod^G_{\mathcal{O}})$, denoted $D^b(A \otimes_{\mathcal{O}(g)} A - mod^G_{\mathcal{O}})$, is well-defined.

[Bez16][Theorem 55] states that the isomorphism above respects the filtrations on both sides. In particular, if we set $\mathcal{O}$ to be the orbit of $N \in \mathfrak{g}$, then we have a canonical isomorphism

$$D_{P^{\mu}} \simeq D^b(A \otimes_{\mathcal{O}(g)} A - mod^G_{\mathcal{O}}).$$

Also it sends the perverse $t$-structure on the left to the usual $t$-structure on the right shifted by $a(\mathfrak{g}) = \dim B_N$. (See [Lus85] for the definition of Lusztig’s $a$-function.)

Now consider a full subcategory $I_{\mathcal{O}}$ of $D_{P^{\mu}}_{<\ell}$ whose objects are (the images of) direct sums of irreducible perverse sheaves and their shifts in $D_{P^{\mu}}_{<\ell}$ (under the quotient map). Under the isomorphism above, it is transferred to the full subcategory of $D^b(A \otimes_{\mathcal{O}(g)} A - mod^G_{\mathcal{O}})$ whose objects are (the images of) direct sums of irreducible $(A \otimes_{\mathcal{O}(g)} A)$-modules set-theoretically supported on $\mathcal{O}$ and their shifts (under the quotient map), which we denote by $I_{\mathcal{O}}$. Since all the irreducible $(A \otimes_{\mathcal{O}(g)} A)$-modules set-theoretically supported on $\mathcal{O}$ are also scheme-theoretically supported on $\mathcal{O}$, we may also identify $I_{\mathcal{O}}$ with the full subcategory of $D^b(A \otimes A - mod^{Z_{G}(N)}_{\mathcal{O}})$ (the bounded derived category of finitely generated $Z_{G}(N)$-equivariant $(A \otimes A)$-modules) whose objects are direct sums of irreducible objects and their shifts. Here, $A \otimes A$ is the fiber of $A$ at $N \in \mathfrak{g}$.

From this description above, we have canonical isomorphisms

$$K(I_{\mathcal{O}}) \simeq K(D_{P^{\mu}}_{<\ell}) \simeq K(D^b(A \otimes_{\mathcal{O}(g)} A - mod^G_{\mathcal{O}})) \simeq K(I_{\mathcal{O}}) \simeq K(D^b(A \otimes A - mod^{Z_{G}(N)}_{\mathcal{O}})).$$

We impose a $\mathbb{C}$-algebra structure on each term so that they are canonically isomorphic as $\mathbb{C}$-algebras. First, Lusztig [Lus97] defined the truncated convolution on $K(I_{\mathcal{O}}) \simeq K(D_{P^{\mu}}_{<\ell})$, which is the usual
convolution followed by applying $p\mathcal{H}^a$, i.e. taking $a(\zeta)$-th perverse cohomology sheaf. Then $K(\mathfrak{I}_e)$ equipped with this algebra structure is canonically isomorphic to the asymptotic Hecke algebra $\mathcal{J}_e$ attached to $\zeta$ (defined over $\mathbb{C}$). On the other hand, this also induces a truncated convolution on $K(D^b(A\otimes\mathcal{O}(g)\mathcal{A} - \text{mod}_G)) \simeq K(\mathfrak{I}_e)$, which is defined by the usual convolution followed by applying $\mathcal{H}^0$, i.e. taking 0-th cohomology sheaf. (This is clear from the comparison of $t$-structures on $D^b(A\otimes\mathcal{O}(g)\mathcal{A} - \text{mod}_G)$ and $D^b(A\otimes\mathcal{O}(g)\mathcal{A} - \text{mod}_G)$.) Therefore, we have a canonical isomorphism of $\mathbb{C}$-algebras

$$\mathcal{J}_e \simeq K(D^b(A_N \otimes A_N - \text{mod}_G(\mathcal{N}))).$$

It is also isomorphic to $K^F_e(A_N \otimes A_N - \text{mod})$ since $F_e$ is the reductive part of $Z_G(\mathcal{N})$.

There exists a natural morphism (of $\mathbb{C}$-vector spaces)

$$K^F_e(A_N \otimes A_N - \text{mod}) \to K(A_N \otimes A_N - \text{mod})$$

which is induced from the forgetful functor. We claim that this morphism is surjective and its kernel is a two-sided ideal of $K^F_e(A_N \otimes A_N - \text{mod})$ (with respect to the truncated convolution), thus it induces a $\mathbb{C}$-algebra structure on $K(A_N \otimes A_N - \text{mod})$. Indeed, according to [BMT3] 5.2.3, every irreducible $(A_N \otimes A_N)$-module can be lifted to an $F_e$-equivariant one and such two lifts are isomorphic up to characters of $F_e$. (Here we use the assumption that $\lambda$ is strict and thus $F_e$ is a torus.) Also, every irreducible $F_e$-equivariant $A_N \otimes A_N$-module arises in this way. From this, the claim easily follows.

On the other hand, inspired by the conjecture of Lusztig [Lus89], Xi [X102] proved that $\mathcal{J}_e$ is canonically isomorphic to $\text{Mat}_{X \times X}(\mathcal{J}_{\Gamma, \Gamma^{-1}})$, where $\Gamma$ is the canonical left cell in $\zeta$, $\mathcal{J}_{\Gamma, \Gamma^{-1}}$ is the asymptotic Hecke algebra attached to $\Gamma \cap \Gamma^{-1}$, and $\lambda = \frac{n_1}{2} \cdot \lambda_{\psi}$ is the number of left cells in $\zeta$ which is also equal to the Euler characteristic of $B_N$. Furthermore, $\mathcal{J}_{\Gamma, \Gamma^{-1}}$ is canonically isomorphic to $\text{Rep}(F_e)$, which in our case is the $\mathbb{C}$-algebra of Laurent polynomials in $l(\lambda)$ variables. Then the $\mathbb{C}$-algebra structure morphism $\mathbb{C} \to \mathcal{J}_{\Gamma, \Gamma^{-1}}$ induces an embedding $\text{Mat}_{X \times X}(\mathbb{C}) \to \mathcal{J}_e$.

Therefore, we obtain a chain of canonical homomorphisms of $\mathbb{C}$-algebras

$$\text{Mat}_{X \times X}(\mathbb{C}) \hookrightarrow \mathcal{J}_e \twoheadrightarrow K^F_e(A_N \otimes A_N - \text{mod}) \to K(A_N \otimes A_N - \text{mod}).$$

We claim that the composition of these morphisms is an isomorphism. Since these are $\mathbb{C}$-algebra morphisms and $\text{Mat}_{X \times X}(\mathbb{C})$ is simple, $\text{Mat}_{X \times X}(\mathbb{C}) \to K(A_N \otimes A_N - \text{mod})$ is injective. (This map is not zero as it preserves the unit.) Now we recall one of the main results in [BMT3].

**Lemma 5.3.** There exists a canonical isomorphism $K(A_N - \text{mod}) \simeq K(B_N)$. Under this isomorphism, the basis $\text{Irr}(A_N)$ of $K(A_N - \text{mod})$ corresponds to the canonical basis of $K(B_N)$ defined in [Lus99].

In particular, it means that $\dim_\mathbb{C} K(A_N \otimes A_N - \text{mod}) = X^2 = \dim_\mathbb{C} \text{Mat}_{X \times X}(\mathbb{C})$. Thus $\text{Mat}_{X \times X}(\mathbb{C}) \to K(A_N \otimes A_N - \text{mod})$ is also surjective, from which the claim follows. Now using the above lemma again, we obtain a canonical isomorphism (of vector spaces)

$$\text{Mat}_{X \times X}(\mathbb{C}) \simeq K(B_N) \otimes K(B_N).$$

### 5.3. Involution $\omega$.

We recall the involution $\omega$ on $G$. Clearly, it also induces an involution on $\mathcal{J}_e$ and $\text{Mat}_{X \times X}(\mathbb{C})$. It is clear that there exists a basis $\{v_{(\Gamma, \Gamma^{-1})} \mid \Gamma, \Gamma' \text{ are left cells in } \zeta\}$ of $\text{Mat}_{X \times X}(\mathbb{C})$ such that $\omega(v_{(\Gamma', \Gamma^{-1})}) = v_{(\omega(\Gamma), \omega(\Gamma^{-1}))}$. Therefore, we have

$$\text{tr}(\omega, \text{Mat}_{X \times X}(\mathbb{C})) = |\{\text{left cells in } \zeta\}|^2.$$
On the other hand, if \( N \in \mathfrak{g} \) is \( \omega \)-stable, then \( \omega \) also induces an action on \( K(B_N) \), and by [HS77, Lemma 3.2] we have (note that \( \rho_2 \) is the cycle type of the longest element in \( W \))
\[
\text{tr}(\omega, K(B_N) \otimes K(B_N)) = \text{tr}(\omega, H^*(B_N) \otimes H^*(B_N)) = (Q^\lambda_{\rho_2(n)}(-1))^2.
\]

However, this still makes sense even when \( N \) is not \( \omega \)-stable. Indeed, for any \( g \in G \) such that \( \text{Ad}(g)(N) = \omega(N) \), we have an isomorphism \( \text{Ad}(g)^*: H^*(B_{\omega(N)}) \to H^*(B_N) \) which does not depend on the choice of \( g \) since \( Z_G(N) \) is connected. Also we have a commutative diagram
\[
\begin{array}{ccc}
H^*(B) & \xrightarrow{\omega} & H^*(B) \\
\downarrow & & \downarrow \\
H^*(B_N) & \xrightarrow{\omega} & H^*(B_N) \\
\end{array}
\]
\[
\text{Ad}(g)^*: H^*(B_N) \to H^*(B_N)
\]

Thus by identifying \( H^*(B_N) \) with the quotient of \( H^*(B) \), the result above is still valid.

We claim that the isomorphism above (of \( \mathbb{C} \)-vector spaces) \( Mat_{X \times X}(\mathbb{C}) \cong K(B) \otimes K(B) \) is \( \omega \)-equivariant. Indeed, note that the constructions of morphisms in \([5,2]\) are all canonical. Therefore, as \( \omega \) on \( Mat_{X \times X}(\mathbb{C}) \) and \( K(B) \otimes K(B) \) are both induced from the same automorphism \( \omega \) on \( G \), our claim is obvious. \footnote{To be precise, we should check that \( \omega \) acts the same way on the Langlands dual of \( G \) as on \( G \), but it is also true since \( \omega \) is self-dual on the root datum of \( G \).}

Thus in particular, we have
\[
|\{\text{left cells in } c \} \omega^2| = \text{tr}(\omega, Mat_{X \times X}(\mathbb{C})) = \text{tr}(\omega, K(B_N) \otimes K(B_N)) = (Q^\lambda_{\rho_2(n)}(-1))^2.
\]

But since
\[
Q^\lambda_{\rho_2(n)}(-1) = \text{tr}(\omega, H^*(B_N)) = \text{tr}(\omega, K(A_N - \text{mod})) = |\text{Irr}(A_N)^\omega| \geq 0,
\]
we have \(|\{\text{left cells in } c \} \omega| = Q^\lambda_{\rho_2(n)}(-1)\). Thus the main theorem is proved.

Remark. The canonical basis of \( K(B) \) in [Lus99] is a signed basis, i.e. there is ambiguity on the choice of signs. On the other hand, \( \text{Irr}(A_N) \subset K(A_N - \text{mod}) \) is an actual basis, and \( \pm \text{Irr}(A_N) \) is mapped to Lusztig’s canonical basis under the isomorphism \( K(A_N - \text{mod}) \cong K(B_N) \). In our proof, it is crucial that \( \omega \) stabilizes not only the signed basis but also \( \text{Irr}(A_N) \) itself.

6. Proof of Proposition \([5,1]\): some combinatorics

This section is devoted to the proof of Proposition \([5,1]\). The argument in this section is explained in [CFKLY] in more detail and the proposition also follows from the results therein. However, we still provided its proof here for the sake of completeness.

6.1. The generalized Robinson-Schensted algorithm. First, we investigate the connection between left cells in \( \hat{W} \) and row-standard Young tableaux under the generalized Robinson-Schensted algorithm originally defined by Shi [Shi86, Shi91]. Following [Lus83b], we identify \( \hat{W} \) with the subgroup of \( \text{Aut}(\mathbb{Z}) \) defined by
\[
\{w \in \text{Aut}(\mathbb{Z}) | \forall i \in \mathbb{Z}, w(n + i) = w(i) + n\}.
\]
We express each \( w \in \text{Aut}(\mathbb{Z}) \) in terms of the sequence \([w(1), w(2), \ldots, w(n)]\), called the window notation. Then we have
\[
s_i = [1, 2, \ldots, i - 1, i + 1, i, i + 2, \ldots, n], \quad s_0 = [0, 2, \ldots, n - 1, n + 1], \quad \tau = [2, 3, \ldots, n, n + 1].
\]

It is easy to check that they satisfy the defining relations of \( \tilde{W} \).

For the description of the generalized Robinson-Schensted algorithm, it is natural to consider an infinite version of (standard) Young tableaux. To that end, we define the notion of an infinite periodic sequence as follows.

**Definition 6.1.** For each \( i \in \mathbb{Z}_{>0} \), let \( \tilde{r}_i \) be a finite sequence of integers. Let \( \tilde{r}_i(1) \) (resp. \( \tilde{r}_i(0) \)) be the smallest positive (resp. largest nonpositive) integer in \( \tilde{r}_i \) (if exists) and label each element in \( \tilde{r}_i \) by its position relative to \( \tilde{r}_i(1) \) or \( \tilde{r}_i(0) \). Then we call \( \tilde{r} = (\tilde{r}_1, \tilde{r}_2, \ldots) \) an infinite periodic sequence modulo \( n \) (IP sequence mod \( n \) for short) if it satisfies the following properties:

1. each \( \tilde{r}_i \) is strictly increasing, thus in particular \( \tilde{r}_i(k) > 0 \) if and only if \( k > 0 \),
2. \( \lim_{i \to \infty} |\tilde{r}_i| = \infty \),
3. for any \( k \in \mathbb{Z} \), the limit \( \lim_{i \to \infty} (\tilde{r}_i(k)) \) exists,
4. there exists \( M \in \mathbb{N} \) such that for any \( i > 0 \) and \( \tilde{r}_i = (\tilde{r}_i(s), \tilde{r}_i(s + 1), \ldots, \tilde{r}_i(t - 1), \tilde{r}_i(t)) \),
   \[
   \tilde{r}_i(k) = \lim_{j \to \infty} \tilde{r}_i(k) \quad \text{for any } s + M \leq k \leq t - M, \quad \text{and}
   \]
5. there exists \( 1 \leq l \leq n \) and \( 1 \leq a_1 < a_2 < \cdots < a_l \leq n \) such that
   \[
   \lim_{i \to \infty} \tilde{r}_i(kl + r) = kn + a_r \quad \text{for any } k \in \mathbb{Z} \text{ and } 1 \leq r \leq l.
   \]

For any such sequence \( \tilde{r} \), it is clear that \( l, a_1, \ldots, a_l \) in (5) are uniquely determined if they exist. We define \( \Psi_n \) to be the function which sends \( \tilde{r} \) to the finite sequence \((a_1, \ldots, a_l)\).

Likewise, we define an infinite periodic tabloid as follows.

**Definition 6.2.** Let \( \tilde{T} = (\tilde{T}_1, \tilde{T}_2, \ldots) \) be an infinite series of Young tabloids such that the following properties hold.

1. There exists \( M' \in \mathbb{N} \) such that \( \tilde{T}_i \) has \( \leq M' \) rows. We define \( l(\tilde{T}) \) to be the smallest \( M' \) which satisfies this property, called the length of \( \tilde{T} \).
2. For each \( 1 \leq j \leq l(\tilde{T}) \), \( \tilde{T}^{(j)} := \{\tilde{T}_i^{(j)}\}_{i \geq 1} \) is an IP sequence mod \( n \) where \( \tilde{T}_i^{(j)} \) is the \( j \)-th row of \( \tilde{T}_i \).

Then we call \( \tilde{T} \) an infinite periodic tabloid modulo \( n \) (IP tabloid mod \( n \) for short). For such \( \tilde{T} \), we similarly define \( \Psi_n(\tilde{T}) \) to be the Young tabloid whose rows are \( \Psi_n(\tilde{T}^{(1)}), \ldots, \Psi_n(\tilde{T}^{(l(\tilde{T}))}) \). Note that an IP sequence mod \( n \) is an IP tabloid mod \( n \) of length 1. We define \( \text{IP}_n \) to be the set of infinite periodic tabloids modulo \( n \).

For any element \( w \in \tilde{W} \), consider the following sequence that is infinite in both ways:
\[
\ldots, w(-3), w(-2), w(-1), w(0), w(1), w(2), w(3), \ldots
\]
We consider a sequence \(\{(a_i, b_i)\}_{i \geq 1}\) such that \(a_i \leq b_i\), \(a_i\) is decreasing, \(b_i\) is increasing, \(\lim_{i \to \infty} a_i = -\infty\), and \(\lim_{i \to \infty} b_i = \infty\). For each \(i\), we consider the standard Young tableau \(\bar{T}_i\) which is the result of the usual Robinson-Schensted algorithm with input \((w(a_i), w(a_i + 1), \ldots, w(b_i - 1), w(b_i))\). Then we obtain a series of standard Young tableau \(\bar{T} = \{\bar{T}_i\}_{i \geq 1}\). Now we apply the argument in \([\text{CPY18} \text{ Section 7}]\) to obtain the following.

**Proposition 6.3.** \(\hat{T} \in IP_n\) and \(l(\hat{T}) \leq n\). Also, \(\Psi_n(\hat{T})\) is the same as the result of the generalized Robinson-Schensted algorithm defined in \([\text{Shi86}, \text{Shi91}]\) applied to \(w^{-1}\). (In particular, \(\Psi_n(\hat{T})\) does not depend on the choice of the sequence \(\{(a_i, b_i)\}_{i \geq 1}\). Moreover, if \(w\) is an element of \(\hat{W}\), then \(\Psi_n(\hat{T})\) is the same as the output of the usual Robinson-Schensted algorithm applied to \(w^{-1}\).

Here \(w^{-1}\) appears instead of \(w\) since we consider the left action of \(\hat{W}\) on \(\mathbb{Z}\) instead of the right one. We define \(Q(w)\) to be such \(\Psi_n(\hat{T})\) in the theorem and set \(P(w) := Q(w^{-1})\). Then by \([\text{Shi86}, \text{Shi91}]\), \(P(w)\) and \(Q(w)\) have the same shape. For \(w, w' \in \hat{W}\), \(Q(w') = Q(w)\) (resp. \(P(w) = P(w')\)) if and only if they are contained in the same left (resp. right) cell. Likewise, \(Q(w)\) and \(Q(w')\) have the same shape if and only if they lie in the same two-sided cell, which is parametrized by the shape of \(Q(w)\).

6.2. **Affine Schützenberger involution and combinatorial \(R\)-matrix.** Recall the involution \(\omega\) acting on \(\hat{W}\). Under the identification of \(\hat{W}\) with the subset of \(\text{Aut}(\mathbb{Z})\), it corresponds to the conjugation by the element \(k \mapsto 1 - k\) in \(\text{Aut}(\mathbb{Z})\). It permutes left cells in \(\hat{W}\), thus defines an involution on the set of row-standard Young tableaux under the generalized Robinson-Schensted correspondence. Also, since \(\omega\) stabilizes each two-sided cell, it restricts to the involution on \(RSYT(\lambda)\) (the set of row-standard Young tableaux of shape \(\lambda\)) for each \(\lambda \vdash n\).

We claim that this action can be described in terms of combinatorial \(R\)-matrices. (This is originally proved by Chmutov-Lewis-Pylyavskyy.) First we recall the definition of combinatorial \(R\)-matrices on the tensor product of single-row Kirillov-Reshetikhin crystals (KR crystals for short). We refer readers to \([\text{Shi05}]\) for a nice exposition on this subject. For \(a, b \in \mathbb{Z}_{\geq 0}\), we regard \(RSYT((a, b))\) as a subset of the vertices of the crystal graph \(\mathbb{B}^b \otimes \mathbb{B}^a\), where \(\mathbb{B}^s\) is the KR crystal of shape \((s)\) (of \(U_q(\widehat{sl}_k)\) for a suitable choice of \(k\)). Then there exists a unique isomorphism \(\mathbb{B}^b \otimes \mathbb{B}^a \to \mathbb{B}^a \otimes \mathbb{B}^b\), which we call the combinatorial \(R\)-matrix, and it restricts to a bijection \(\mathcal{R} : RSYT((a, b)) \to RSYT((b, a))\).

\([\text{Shi05} \text{ Example 4.10}]\) describes this operation using jeu-de-taquin and sliding process. Here we briefly explain his description with an example.

**Example 6.4.** Let \(a = 4, b = 3\) and \(T = \begin{array}{cccc} & & & \\ & & 4 & \\ & 3 & & \\ 2 & & & \\ 1 & 2 & 5 & \end{array} \in RSYT((a, b))\). To apply \(\mathcal{R}\), we first draw the skew-shaped standard Young tableau \(\begin{array}{cccc} & & & \\ & & 4 & \\ & 3 & & \\ 2 & & & \\ 1 & 2 & 5 & \end{array}\) obtained from sliding the first row to the right, and apply jeu-de-taquin process until each row has the correct number of boxes.

\[
\begin{array}{cccc} & & & \\ & & 4 & \\ & 3 & & \\ 2 & & & \\ 1 & 2 & 5 & \\
\end{array} \rightarrow \begin{array}{cccc} & & & \\ & & 4 & \\ & 3 & & \\ 2 & & & \\ 1 & 2 & 5 & \\
\end{array} \rightarrow \begin{array}{cccc} & & & \\ & & 4 & \\ & 3 & & \\ 2 & & & \\ 1 & 2 & 5 & \\
\end{array} \rightarrow \begin{array}{ccccc} & & & & \\ & & 4 & & \\ & 3 & & & \\ 2 & & & & \\
\end{array}
\]

As a result, we have \(\mathcal{R}(T) = \begin{array}{ccccc} & & & & \\ & & 4 & & \\ & 3 & & & \\ 2 & & & & \\
\end{array}\). Note that both \(\begin{array}{cccc} & & & \\ & & 4 & \\ & 3 & & \\ 2 & & & \\ 1 & 2 & 5 & \end{array}\) and \(\begin{array}{ccccc} & & & & \\ & & 4 & & \\ & 3 & & & \\ 2 & & & & \\
\end{array}\) are jeu-de-taquin equivalent to the standard Young tableau \(\begin{array}{cccc} & & & \\ & & 4 & \\ & 3 & & \\ 2 & & & \\ 1 & 2 & 5 & \end{array}\). In general, the combinatorial \(R\)-matrix does not change the associated jeu-de-taquin equivalent standard Young tableau.
Or, first we again consider \( \begin{bmatrix} 1 & 2 & 8 \\ 3 & 4 & 9 \\ 5 & 6 & 7 \end{bmatrix} \) and slide each box on the second row to the rightest with preserving semi-standard property to get \( \begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 8 \\ 7 & 6 & 9 \end{bmatrix} \). Then, push down the correct number of leftmost boxes (in this case we push down 4 - 3 = 1 box) from the first row to obtain \( \begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{bmatrix} \). Thus we also see that \( \mathcal{R}(T) = \begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{bmatrix} \). If \( a < b \), then we first slide each box in the first row to the leftest with preserving semi-standard property and push up the correct number of rightmost boxes from the second row.

This combinatorial \( R \)-matrix is generalized to any finite tensor product of single-row KR crystals. In particular, for any sequence of positive integers \( \lambda = (\lambda_1, \ldots, \lambda_r) \) (not necessarily a partition) we similarly define

\[
\mathcal{R}_i : \text{RSYT}(\lambda) \to \text{RSYT}((\lambda_1, \ldots, \lambda_{i-1}, \lambda_{i+1}, \lambda_i, \lambda_{i+2}, \ldots, \lambda_r))
\]

to be the corresponding combinatorial \( R \)-matrix. From the theory of crystals, we easily deduce the following properties of \( \mathcal{R} \).

1. \( \mathcal{R}_i^2 = \text{Id} \).
2. \( \mathcal{R}_i \mathcal{R}_{i+1} \mathcal{R}_i = \mathcal{R}_{i+1} \mathcal{R}_i \mathcal{R}_{i+1} \).
3. If \( \lambda_i = \lambda_{i+1} \), then \( \mathcal{R}_i = \text{Id} \).
4. In general, if \( \lambda_1, \ldots, \lambda_r, \mu_1, \ldots, \mu_r \in \mathbb{N} \) such that \( \{\lambda_1, \ldots, \lambda_r\} = \{\mu_1, \ldots, \mu_r\} \), then all the compositions of combinatorial \( R \)-matrices from \( \text{RSYT}((\lambda_1, \ldots, \lambda_r)) \) to \( \text{RSYT}((\mu_1, \ldots, \mu_r)) \) give the same map.

As promised, we illustrate \( \omega \) in terms of combinatorial \( R \)-matrices as follows.

**Proposition 6.5.** Let \( \lambda \vdash n \) be a partition. For a given \( T \in \text{RSYT}(\lambda) \), \( T \mapsto \omega(T) \) is equivalent to the following process:

1. rotate \( T \) by 180° and push each row to the left so that it becomes a Young tabloid,
2. substitute each entry \( i \) by \( n + 1 - i \) to make it row-standard, and
3. apply combinatorial \( R \)-matrices accordingly to retain the original shape \( \lambda \).

First, we restrict our attention to \( W \subset \widehat{W} \) and \( \text{SYT}(\lambda) \subset \text{RSYT}(\lambda) \) (the set of standard Young tableaux of shape \( \lambda \)). Then for any \( w \in W \), \( \omega(w) = w_0 w w_0 \) where \( w_0 \in W \) is the longest element in \( W \). Under the Robinson-Schensted algorithm, this corresponds to the usual Schützenberger involution. Also, it follows from [Stan09, Appendix A] that this involution is the same as the one described in Proposition 6.5. Therefore, this proposition is true for elements in \( \text{SYT}(\lambda) \).

In general, let \( \bar{T} \) be an IP tabloid mod \( n \) such that \( \Psi_n(\bar{T}) \) is a row-standard Young tabloid. We claim that combinatorial \( R \)-matrices and the function \( \Psi_n \) behave well together as follows.

**Lemma 6.6.** For \( 1 \leq i \leq l(\bar{T}) - 1 \), let \( \mathcal{R}_i(\bar{T}) \) be the series \( (\mathcal{R}_i(\bar{T}_1), \mathcal{R}_i(\bar{T}_2), \ldots) \). Then \( \mathcal{R}_i(\bar{T}) \) is again an IP tabloid mod \( n \) and we have \( \Psi_n(\mathcal{R}_i(\bar{T})) = \mathcal{R}_i(\Psi_n(\bar{T})) \).

**Proof.** It suffices to assume that \( l(\bar{T}) = 2 \) and \( i = 1 \). In this case, it is an easy combinatorial exercise using the description of \( \mathcal{R} \) in terms of sliding process in [Shi05, Example 4.10]. \( \square \)
Example 6.7. Suppose $\tilde{T}$ is an IP tabloid mod 7 such that $\Psi_7(\tilde{T}) = \begin{array}{cccccccc} 1 & 4 & 6 & 7 & 10 & 11 & 13 & 14 \\ 2 & 3 & 5 & 8 & 9 & 12 & 15 & 16 \\ 0 & 1 & 2 & 4 & 6 & 8 & 10 & 12 \end{array}$ Then (the limit of) each row of $\tilde{T}$ looks like

\[
\begin{array}{cccccccccc}
\cdots & -13 & -12 & -9 & -6 & -5 & -2 & 1 & 2 & 5 & 8 & 9 & 12 & 15 & 16 & 19 & \cdots \\
\cdots & -13 & -10 & -8 & -7 & -4 & -3 & -1 & 0 & 3 & 4 & 6 & 7 & 10 & 11 & 13 & 14 & 17 & 18 & 20 & 21 & \cdots 
\end{array}
\]

and

\[
\begin{array}{cccccccccc}
\cdots & -13 & -12 & -9 & -6 & -5 & -2 & 1 & 2 & 5 & 8 & 9 & 12 & 15 & 16 & 19 & \cdots \\
\cdots & -13 & -10 & -8 & -7 & -4 & -3 & -1 & 0 & 3 & 4 & 6 & 7 & 10 & 11 & 13 & 14 & 17 & 18 & 20 & 21 & \cdots 
\end{array}
\]

Now we put each box in the second row to the rightest with keeping semi-standard property. Then it looks like

\[
\begin{array}{cccccccccc}
\cdots & -13 & -12 & -9 & -6 & -5 & -2 & 1 & 2 & 5 & 8 & 9 & 12 & 15 & 16 & 19 & \cdots \\
\cdots & -13 & -10 & -8 & -7 & -4 & -3 & -1 & 0 & 3 & 4 & 6 & 7 & 10 & 11 & 13 & 14 & 17 & 18 & 20 & 21 & \cdots 
\end{array}
\]

But this is a concatenation of \begin{array}{cccccccc}
\begin{array}{cccccccc}
1 & 4 & 6 & 7 & 10 & 11 & 13 & 14 \\
2 & 3 & 5 & 8 & 9 & 12 & 15 & 16 \\
0 & 1 & 2 & 4 & 6 & 8 & 10 & 12 \end{array}
\end{array} and its shifts by a multiple of 7. Note that \begin{array}{cccccccc}
\begin{array}{cccccccc}
1 & 4 & 6 & 7 & 10 & 11 & 13 & 14 \\
2 & 3 & 5 & 8 & 9 & 12 & 15 & 16 \\
0 & 1 & 2 & 4 & 6 & 8 & 10 & 12 \end{array}
\end{array} appears in the usual combinatorial $R$-matrix calculation on $\Psi_7(\tilde{T}) = \begin{array}{cccccccc} 1 & 4 & 6 & 7 & 10 & 11 & 13 & 14 \\ 2 & 3 & 5 & 8 & 9 & 12 & 15 & 16 \\ 0 & 1 & 2 & 4 & 6 & 8 & 10 & 12 \end{array}$ (cf. Example 6.4). Also, if one pushes down boxes from the first row, then it corresponds to pushing down the box of entry 3 in \begin{array}{cccccccc}
\begin{array}{cccccccc}
1 & 4 & 6 & 7 & 10 & 11 & 13 & 14 \\
2 & 3 & 5 & 8 & 9 & 12 & 15 & 16 \\
0 & 1 & 2 & 4 & 6 & 8 & 10 & 12 \end{array}
\end{array}. Therefore, in this case we get $\Psi_7(R(\tilde{T})) = R(\Psi_7(\tilde{T}))$.

Indeed, it is not hard to show that the image of $\Psi_n \circ R$ only depends on $\Psi_n(\tilde{T})$; if $\tilde{T}, \tilde{T}'$ are two IP tabloids mod $n$ such that $\Psi_n(\tilde{T}) = \Psi_n(\tilde{T}')$, then indeed we have $\Psi_n(R(\tilde{T})) = \Psi_n(R(\tilde{T}'))$. In other words, one may simply ignore “finite noise” part in both ends of IP sequences mod $n$ because of the condition (4) in Definition 6.1.

Proof of Proposition 6.3 Suppose $w \in \tilde{W}$ is given and $\tilde{T} = (T_1, T_2, \ldots)$ is an IP tabloid mod $n$ constructed in Proposition 6.3. Here we choose $(a_i, b_i)_{i \geq 1}$ such that $a_i + b_i = 1$. (This assumption is not necessary but it simplifies the proof.) In other words, each $T_i$ is the output of the usual Robinson-Schensted algorithm applied to the sequence $w(a_1), w(a_1 + 1), \ldots, w(b_i - 1), w(b_i)$. If we apply $\omega$, then it corresponds to replacing the sequence $w(a_1), w(a_1 + 1), \ldots, w(b_i - 1), w(b_i)$ with $\omega(w)(a_i), \omega(w)(a_i + 1), \ldots, \omega(w)(b_i - 1), \omega(w)(b_i)$, i.e.

$$1 - w(1 - a_i), 1 - w(-a_i), \ldots, 1 - w(2 - b_i), 1 - w(1 - b_i)$$

which is equal to

$$1 - w(b_i), 1 - w(b_i - 1), \ldots, 1 - w(1 + a_i), 1 - w(a_i)$$

since $a_i + b_i = 1$. According to [Sta86] Appendix A], this is similar to the usual Schützenberger involution. Indeed, the output of usual Robinson-Schensted algorithm applied to $1 - w(b_i), 1 - w(b_i - 1), \ldots, 1 - w(1 + a_i), 1 - w(a_i)$ can also be obtained from $T_i$ by the following process.

(1) Rotate $\tilde{T}_i$ by $180^\circ$ and push each row to the left so that it becomes a Young tabloid,

(2) substitute each entry $i$ by $1 - i$, and

(3) find a standard Young tableau which is jeu-de-taquin equivalent to the result of (2) with the same shape as $\tilde{T}_i$.

From the properties of combinatorial $R$-matrices, step (3) is also equivalent to the following.

(3') apply combinatorial $R$-matrices accordingly to retain the original shape of $\tilde{T}_i$. 

Now we apply $\Psi_n$ on the output of each $\tilde{T}_i$ under this process. Step (1) obviously commutes with $\Psi_n$, and so does step (2) modulo $n$. Also, step (3) commutes with $\Psi_n$ by Lemma 6.6. Therefore, $\omega(\Psi_n(\tilde{T}))$ is obtained from $T = \Psi_n(\tilde{T})$ by applying the process below:

1. Rotate $T$ by $180^\circ$ and push each row to the left so that it becomes a Young tabloid, 
2. substitute each entry $i$ by $1 - i$ modulo $n$, say $n + 1 - i$, and
3. apply combinatorial $R$-matrices accordingly to retain the original shape of $T$.

But this is what we want to prove. 

The description of $\omega$ in terms of combinatorial $R$-matrices has an advantage that it can be generalized to any row-standard Young tabloid, say $RSYT(\lambda)$ where $\lambda$ is a finite sequence of positive integers which is not necessarily a partition, since the method described in Proposition 6.5 does not rely on the condition that $\lambda$ is a partition. If we write such a generalization again by $\omega$, then the following lemma is easily proved.

**Lemma 6.8.** Let $\lambda = (\lambda_1, \ldots, \lambda_r)$ be a finite sequence of positive integers. Then for $1 \leq i \leq r - 1$, the two maps

$$\omega \circ \mathcal{R}_i, \mathcal{R}_i \circ \omega : RSYT(\lambda) \to RSYT((\lambda_1, \ldots, \lambda_{i-1}, \lambda_{i+1}, \lambda_i, \lambda_{i+2}, \ldots, \lambda_r))$$

coincide. In other words, $\mathcal{R}_i$ and $\omega$ “commute”.

**6.3. Proof of Proposition 6.1.** By Proposition 6.3 and Lemma 6.8, we may illustrate $T \mapsto \omega(T)$ for $T \in RSYT(\lambda \cup (k, k))$ by the following process.

1. Apply $\mathcal{R}$ accordingly to obtain a row-standard Young tabloid of shape $(k, \lambda_1, \ldots, \lambda_r, k)$.
2. Apply (the generalized version of) $\omega$ which is an involution on $RSYT((k, \lambda_1, \ldots, \lambda_r, k))$.
3. Apply $\mathcal{R}$ accordingly to obtain a row-standard Young tableau of shape $\lambda \cup (k, k)$.

Note that step (1) and (3) are inverse to each other. Therefore by Lemma 6.8 we have

$$|RSYT(\lambda \cup (k, k))^{\omega}| = |RSYT((k, \lambda_1, \ldots, \lambda_r, k))^{\omega}|.$$

Now, we consider the surjection

$$\Phi : RSYT((k, \lambda_1, \ldots, \lambda_r, k)) \to RSYT(\lambda)$$

which sends $T = (T^{(1)}, T^{(2)}, \ldots, T^{(r)}, T^{(r+1)}, T^{(r+2)})$ to the renormalization of $(T^{(2)}, \ldots, T^{(r)}, T^{(r+1)})$, i.e. removes the first and the last row (of length $k$) of $T$ and renormalizes the result so that the entries are $1, 2, \ldots, |\lambda|$. For example,

If $k = 2, \lambda = (4, 3)$, and $T = \begin{bmatrix}
1 & 2 & 3 & 4 \\
1 & 2 \\
2 & 3 & 4
\end{bmatrix}$

then $\Phi(T) = \begin{bmatrix}
1 & 2 & 3 & 4 \\
1 & 2 & 4
\end{bmatrix}$.

Now, from the description of $\omega$ (Proposition 6.5), $T$ is $\omega$-stable if and only if

1. there exists $a_1, a_2, \ldots, a_k \in \{1, 2, \ldots, n\}$ such that $a_1 < a_2 < \cdots < a_k$ and $\{a_1, \ldots, a_k\} \cap \{n - a_1, \ldots, n - a_k\} = \emptyset$, and the first (resp. last) row of $T$ is $(a_1, a_2, \ldots, a_k)$ (resp. $(n - a_k, n - a_{k-1}, \ldots, n - a_1)$),
2. $\Phi(T)$ is $\omega$-stable.
Thus, $\varphi(\lambda \cup (k,k))$ equals $\varphi(\lambda)$ multiplied by the number of choices of such $\{a_1, a_2, \ldots, a_k\}$, which is equal to $\binom{n}{k} 2^k$ where $m = \lfloor n/2 \rfloor$. But this is what we want to prove.
