Abstract

We propose a deformation of $\mathcal{N} = 4$ SYM theory induced by nonanticommutative star product. The deformation introduces new bosonic terms which we identify with the corresponding Myers terms of a stack of D3-branes in the presence of a five-form RR flux. We take this as an indication that the deformed lagrangian describes D3-branes in such a background. The vacuum states of the theory are also examined. In a specific case where the $U(1)$ part of the gauge field is nonvanishing the (anti)holomorphic transverse coordinates of the brane sit on a fuzzy two-sphere. For a supersymmetric vacuum the antiholomorphic coordinates must necessarily commute. However, we also encounter non-supersymmetric vacua for which the antiholomorphic coordinates do not commute.
1 Introduction

The study of supersymmetric D-branes in the background of a RR flux has revealed new structures on the corresponding superspace. In particular, it turns out that in this background the coordinates of the superspace on the brane do not (anti)commute with each other [1, 2]. Interestingly, this is the sole effect of the background, and hence, as far as the dynamics of D-branes is concerned, one can basically ignore the background fields and in effect assume that the coordinates in superspace do not (anti)commute. The nice thing is that even with such nonanticommuting coordinates one can still construct a super Yang-Mills theory preserving half the $\mathcal{N} = 1$ supersymmetry [2]. If, however, one insists on preserving the whole supersymmetry, then as shown by Ooguri and Vafa [1], one further needs to deform the anticommutation relation between the spinor fields on the worldvolume of the brane. The resulting $\mathcal{N} = 1/2$ SYM theory and its generalizations have been extensively studied, see [9]-[36], for instance.

In the present work we provide a setting for the study of D3-branes in a graviphoton background. As said above, the graviphoton background introduces a new structure on the superspace coordinates. Accordingly, one needs to refine the superfields definitions, and in writing the lagrangian use star products instead of ordinary products. Explicitly, to write an effective lagrangian for D3-branes we proceed as follows. First, we write the $\mathcal{N} = 4$ lagrangian in terms of $\mathcal{N} = 1$ superfields. The superfields are adapted according to the nonanticommutative nature of the superspace. And finally we use the corresponding nonanticommutative star product in between the superfields.

There exists, however, a direct way of writing the effective lagrangian and checking whether the above construction is consistent. In so doing, we first note that the graviphoton flux $C_{\mu\nu}$ is coming from a ten-dimensional five-form RR flux $C_{\mu\nuijkl}$ upon compactification to four dimensions. On the other hand, it is known that how D3-branes respond to this flux; it is through the Chern-Simons action and the Myers terms. For a particular choice of a five-form flux with a zero energy momentum tensor this term has been calculated in [38]. Here, upon a nonanticommutative deformation of $\mathcal{N} = 4$ SYM theory, we show that the same Myers terms are reproduced. Though, the fermionic terms as well as the supersymmetry transformations will be different than the ones in [38]. Having derived the lagrangian, we examine the vacuum states of the theory. In the absence of the fermionic fields the vacuum states are the same as those in ordinary $\mathcal{N} = 4$ theory. In particular, since the theory is defined on Euclidean space, we can have new configurations where the holomorphic scalars, $\phi_i$'s, obey an $SU(2)$ algebra forming a fuzzy two-sphere. Being a vacuum state, the whole configuration will have a zero action. However, in the

---

1 For earlier works on nonanticommutative superspace see [3]-[8].

2 As the $\mathcal{N} = 4$ supercharges carry internal $SU(4)$ indices, one can think of some more general deformations of the supersymmetry algebra. For instance, in the case of $\mathcal{N} = 2$ supersymmetry, variant deformations have been considered in [37].
deformed theory it is also possible to have supersymmetric vacua where a fermionic field \( \bar{\lambda} \) and the gauge field \( A_\mu \) are nonzero. Furthermore, we will see that there are vacuum configurations which break supersymmetry. These are characterized by nonzero \( U(1) \) connections together with noncommuting \textit{antiholomorphic} constant scalar fields.

The organization of this paper is as follows. In the next section, we begin with the preliminaries of the nonanticommutative superspace, and adapt the superfield definitions accordingly. We then write the \( \mathcal{N} = 4 \) lagrangian in terms of the \( \mathcal{N} = 1 \) superfield language, and use the star product to multiply the superfields. This defines a nonanticommutative deformation of \( \mathcal{N} = 4 \) theory. In section 3, we discuss the bosonic terms of the lagrangian which linearly depend on the deformation parameter. These terms are precisely the Myers terms appearing in the effective lagrangian of multiple D3-branes in the background of a five-form RR flux. In section 4, we discuss the vacuum states of the deformed theory. When the self-dual part of the gauge field strength is nonzero, we will argue how the commutation relation of (anti)holomorphic scalars are deformed to that of coordinates of a fuzzy two-sphere. The summary and conclusions are brought in the last section.

2 Nonanticommutative Deformation of \( \mathcal{N} = 4 \) SYM

As mentioned in the Introduction, there are two approaches to study the dynamics of D-branes in the graviphoton background field. Either one can take care of the background by adding appropriate Chern-Simons terms to the DBI action using the Myers prescription [39, 38]. Or alternatively, write the \( \mathcal{N} = 4 \) theory in terms of \( \mathcal{N} = 1 \) superfields and use the nonanticommmutative star product. In this section we follow the latter approach, and show that it leads to the correct Myers terms for a stack of D3-branes in a five-form flux. In this way, we propose a lagrangian which describes D3-branes in the corresponding graviphoton background. Note that a similar equivalence in the description of D-branes in a Kalb-Ramond \( B \) background occurs; one can either introduce the \( B \) field directly into the DBI action, or instead, introduce it through an appropriate star product between the fields [40].

2.1 Preliminaries

To begin with, let us recall the construction of the nonanticommutative superspace in [2] where the \( \theta \) coordinates satisfy the following anticommutation relation

\[
\{ \theta^\alpha, \theta^\beta \} = C^{\alpha\beta},
\]

for \( C^{\alpha\beta} \) a constant symmetric matrix. This, however, requires an ordering for the product of functions of \( \theta \). We choose then to define

\[
f(\theta) \ast g(\theta) = f(\theta) \exp \left(-\frac{C^{\alpha\beta}}{2} \frac{\partial}{\partial \theta^\alpha} \frac{\partial}{\partial \theta^\beta} \right) g(\theta).
\]
For the chiral multiplet we have
\[ \Phi(y, \theta) = \phi(y) + \sqrt{2} \theta \psi(y) + \theta \theta F(y). \] (3)

However, for the antichiral multiplet and \( V \) we choose
\[ \bar{\Phi}(\bar{y}, \bar{\theta}) = \bar{\phi}(\bar{y}) + \sqrt{2} \bar{\theta} \bar{\psi}(\bar{y}) \]
\[ + \bar{\theta} \bar{\theta} \left( F(\bar{y}) + \frac{i}{2} C^{\mu \nu} \{ F_{\mu \nu}, \phi \} + i C^{\mu \nu} \left\{ A_\mu, D_\mu \bar{\phi} - \frac{i}{4} [A_\mu, \bar{\phi}] \right\} (\bar{y}) \right) \]
\[ V(y, \theta, \bar{\theta}) = -\theta \sigma^\mu \bar{\theta} A_\mu(y) + i \theta \bar{\theta} \bar{\lambda}(y) - i \bar{\theta} \bar{\theta} \theta^a \left( \lambda_a(y) + \frac{1}{4} \epsilon_{\alpha \beta} C^{\beta \gamma} \sigma_\gamma^\mu \{ \bar{\lambda}^\gamma, A^\mu \} \right) \]
\[ + \frac{1}{2} \theta \bar{\theta} \bar{\theta} \bar{\theta} \left( D(y) - i \partial_\mu A_\mu(y) \right), \] (4)

where
\[ C^{\mu \nu} \equiv C^{\alpha_\beta} \epsilon_{\beta_\gamma} (\sigma^{\mu \nu})_\alpha^\gamma. \] (5)

Also note that \( y \) and \( \bar{y} \) are related through
\[ \bar{y}^\mu = y^\mu - 2i \theta \sigma^\mu \bar{\theta}, \] (6)

together with
\[ [y^\mu, y^\nu] = [y^\mu, \theta^\alpha] = [y^\mu, \bar{\theta}^\dot{\alpha}] = 0 \] (7)

and thus
\[ [\bar{y}^\mu, \bar{y}^\nu] = 4 \bar{\theta} \bar{\theta} C^{\mu \nu}. \] (8)

Since \( \bar{y} \) coordinates do not commute, for the antichiral superfields we define the following star product:
\[ \bar{\Phi}_1(\bar{y}, \bar{\theta}) \ast \bar{\Phi}_2(\bar{y}, \bar{\theta}) = \bar{\Phi}_1(\bar{y}, \bar{\theta}) \exp \left( 2 \bar{\theta} \bar{\theta} C^{\mu \nu} \frac{\partial \bar{\theta}}{\partial \bar{y}^\mu} \frac{\partial \bar{\theta}}{\partial \bar{y}^\nu} \right) \bar{\Phi}_2(\bar{y}, \bar{\theta}) \]
\[ = \bar{\Phi}_1(\bar{y}, \bar{\theta}) \bar{\Phi}_2(\bar{y}, \bar{\theta}) + 2 \bar{\theta} \bar{\theta} C^{\mu \nu} \frac{\partial \bar{\Phi}_1(\bar{y}, \bar{\theta})}{\partial \bar{y}^\mu} \frac{\partial \bar{\Phi}_2(\bar{y}, \bar{\theta})}{\partial \bar{y}^\nu}. \] (9)

Notice that the choice of \( \Phi \) and \( V \) in (4) ensures that the gauge transformations take the canonical form [2, 41]. The chiral and antichiral field strength superfields are
\[ W_\alpha = -\frac{1}{4} D \bar{D} e^{-V} D_\alpha e^V, \]
\[ \bar{W}_\dot{\alpha} = \frac{1}{4} D e^V \bar{D}_\dot{\alpha} e^{-V}. \] (10)
2.2 The $C$-deformed Lagrangian

With these preliminaries on the $C$-deformed superspace, we are now ready to set
the stage for a particular nonanticommutative version of $\mathcal{N} = 4$ SYM. A simple
prescription for writing the corresponding lagrangian is to express the
lagrangian in terms of $\mathcal{N} = 4$ superfields and then use the above star products in
between the superfields. In so doing, we recall that the field content of
"grangian in terms of $N = 4$ is manifestly invariant under the following gauge transforma-
tions

\begin{align*}
L &= \int d^2 \theta \; \text{tr} \left( W^\alpha \star W_\alpha \right) + \int d^2 \bar{\theta} \; \text{tr} \left( \overline{W}_\dot{\alpha} \star \overline{W}^{\dot{\alpha}} \right) \\
&\quad + \int d^2 \theta d^2 \bar{\theta} \; \text{tr} \sum_{i=1}^{3} \left( \bar{\Phi}_i \star e^V \star \Phi_i \star e^{-V} \right) \\
&\quad + \frac{\sqrt{2}}{2} \int d^2 \theta \; \text{tr} \left( \Phi_1 \star [\Phi_2 \star \Phi_3] \right) - \frac{\sqrt{2}}{2} \int d^2 \bar{\theta} \; \text{tr} \left( \bar{\Phi}_1 \star [\bar{\Phi}_2 \star \bar{\Phi}_3] \right). \tag{11}
\end{align*}

The above lagrangian is manifestly invariant under the following gauge transformations

\begin{align*}
e^V &\rightarrow e^{-i\Lambda} \ast e^V \ast e^{i\Lambda} \\
W^\alpha &\rightarrow e^{-i\Lambda} \ast W^\alpha \ast e^{i\Lambda} \\
\overline{W}_{\dot{\alpha}} &\rightarrow e^{-i\overline{\Lambda}} \ast \overline{W}_{\dot{\alpha}} \ast e^{i\overline{\Lambda}} \\
\Phi_i &\rightarrow e^{-i\Lambda} \ast \Phi_i \ast e^{i\Lambda} \\
\bar{\Phi}_i &\rightarrow e^{-i\overline{\Lambda}} \ast \bar{\Phi}_i \ast e^{i\overline{\Lambda}}.
\end{align*}

Here $\Lambda$ and $\overline{\Lambda}$ are the chiral and antichiral superfields, respectively. Also note
that the superpotential in (11) breaks the original $SO(6)$ R-symmetry to an $SO(3)$ subgroup.

Let us now apply the star product rules (2) and (9) in (11) and do the integrals
over the odd coordinates of superspace and write down the lagrangian in terms of
the component fields

\begin{align*}
L &= \text{tr} \left( -\frac{1}{4} F^{\mu\nu} F_{\mu\nu} + i\chi_\mu \sigma^\mu D_\mu \chi + \frac{1}{2} D^2 - D^\mu \tilde{\phi}_i D_\mu \phi_i + i \tilde{\psi}_i \sigma^\mu D_\mu \psi_i + \bar{F}_i F_i \\
&\quad - \frac{i\sqrt{2}}{2} [\tilde{\phi}_i, \psi_i] \lambda + \frac{i\sqrt{2}}{2} [\phi_i, \tilde{\psi}_i] \tilde{\lambda} + \frac{D}{2} [\phi_i, \tilde{\phi}_j] - \frac{i}{2} C^{\mu\nu} F_{\mu\nu} \lambda \tilde{\lambda} + \frac{|C|^2}{8} (\lambda \tilde{\lambda})^2 \\
&\quad + \frac{i}{2} C^{\mu\nu} F_{\mu\nu} \{ \tilde{\phi}_i, F_i \} - \frac{\sqrt{2}}{2} C^{\alpha\beta} \{ D_\mu \tilde{\phi}_i, (\sigma^\mu \lambda)_\alpha \} \psi_i - \frac{|C|^2}{16} [\tilde{\phi}_i, \lambda] [\tilde{\lambda}, F_i] \\
&\quad + \frac{\sqrt{2}}{2} \epsilon_{ijk} \left( F_i \tilde{\phi}_j \tilde{\phi}_k - \tilde{\phi}_j \psi_i \tilde{\phi}_k - \frac{1}{12} |C|^2 F_i F_j F_k \right) \tag{12} \\
&\quad - \frac{\sqrt{2}}{2} \epsilon_{ijk} \left( \bar{F}_i \tilde{\phi}_j \tilde{\phi}_k - \tilde{\phi}_j \psi_i \tilde{\phi}_k + \frac{2i}{3} C^{\mu\nu} D_\mu \tilde{\phi}_i \tilde{\phi}_j \tilde{\phi}_k + \frac{2}{3} C^{\mu\nu} D_\mu \tilde{\phi}_i D_\nu \tilde{\phi}_j \tilde{\phi}_k \right) \right)
\end{align*}
where \(|C|^2 = C^{\mu\nu}C_{\mu\nu}\), and \(i, j, \ldots = 1, 2, 3\). Note that terms in the last two lines are coming from the deformed superpotential. The covariant derivatives in the last term appear exactly because of the antichiral superfield definition we used in (4).

### 3 Myers terms

In this section we are going to examine the bosonic terms of the superpotential. In particular, we will see that the bosonic terms which are linear in \(C\) can be identified with the Myers terms. Consider a stack of D3-branes in the presence of a five-form RR flux \(C_{\mu\nu\alpha\beta\gamma}\). We choose an RR flux which has a zero energy-momentum tensor and thus it has no back reaction on the metric. The RR flux affects the effective action of the D3-branes through the Chern-Simons term, and Myers provides the way one has to calculate this term for multiple branes [39]. For our particular choice of RR flux, this term has been worked out in [38]. Adapting to our conventions in here this term reads

\[
S_{CS} = \frac{\alpha'}{24g_s^2} \epsilon^{\mu\nu\rho\sigma} \int C_{\mu\nu\alpha\beta\gamma} \text{tr} \left( -i \bar{\psi}^i \bar{\phi}^j \bar{\phi}^k F_{\rho\sigma} + 2 \bar{\phi}^i D_\rho \bar{\phi}^j D_\sigma \bar{\phi}^k \right) d^4x. \tag{13}
\]

In the following we show that if we solve for the auxiliary fields in (12) and take \(C_{\mu\nu} \epsilon_{ijk} \sim C_{\mu\nu\alpha\beta\gamma}\), then we reproduce the Myers term in (13). So let us first solve for the auxiliary fields, \(D, F_i\) and \(\bar{F}_i\), using their equations of motion. This yields

\[
D = -\frac{1}{2} [\bar{\phi}_i, \bar{\phi}_i] \\
F_i = \frac{\sqrt{2}}{2} \epsilon_{ijk} \bar{\phi}^j \bar{\phi}^k \\
\bar{F}_i = -\frac{i}{2} C^{\mu\nu} \{ F_{\mu\nu}, \bar{\phi}_i \} + \frac{|C|^2}{16} \{ [\bar{\phi}_i, \bar{\lambda}], \bar{\lambda} \} - \frac{\sqrt{2}}{2} \epsilon_{ijk} \left( \bar{\phi}^j \bar{\phi}^k - \frac{|C|^2}{4} F^{ij} F^k \right) \tag{14}
\]

Plugging back the auxiliary fields (14) into (12) the lagrangian reads

\[
\mathcal{L} = \text{tr} \left( -\frac{1}{4} F^{\mu\nu} F_{\mu\nu} + i \bar{\lambda} \sigma^\mu D_\mu \lambda - D^\mu \bar{\phi}_i D_\mu \phi_i + i \bar{\psi}_i \sigma^\mu D_\mu \psi_i \\
- \frac{1}{8} [\phi_i, \bar{\phi}_i]^2 + \frac{1}{4} [\phi_j, \phi_k] [\bar{\phi}^j, \bar{\phi}^k] + \frac{\sqrt{2}}{2} \epsilon_{ijk} \left( \bar{\psi}^j \bar{\psi}^k - \phi^i \psi^i \psi^j \right) \\
- \frac{i \sqrt{2}}{2} [\bar{\phi}_i, \psi_i] \lambda + \frac{i \sqrt{2}}{2} [\phi_i, \bar{\psi}_i] \bar{\lambda} \\
- \frac{i}{2} C^{\mu\nu} F_{\mu\nu} \bar{\lambda} \lambda + \frac{1}{8} |C|^2 (\bar{\lambda} \lambda)^2 - \frac{\sqrt{2}}{2} C^{\alpha\beta} \{ D_\mu \bar{\phi}_i, (\sigma^\nu \bar{\lambda})_\alpha \} \psi_{\beta i} \\
- \frac{\sqrt{2}}{32} |C|^2 \epsilon_{ijk} [\bar{\phi}^i, \lambda] [\bar{\lambda}, \bar{\phi}^j \bar{\phi}^k] - \frac{1}{48} |C|^2 \epsilon_{imn} \epsilon_{jkl} \bar{\phi}^m \bar{\phi}^n \bar{\phi}^k [\bar{\phi}^i, \bar{\phi}^j] \\
- \frac{\sqrt{2}}{6} \epsilon_{ijk} \left( -i C^{\mu\nu} F_{\mu\nu} \bar{\phi}^j \bar{\phi}^k + 2 C^{\mu\nu} D_\mu \bar{\phi}^j D_\nu \bar{\phi}^k \right) \right), \tag{15}
\]
which is invariant under the so-called $N = 1/2$ supersymmetry transformations:

\[
\delta A_\mu = -i \bar{\lambda} \sigma_\mu \xi \\
\delta \lambda = -\frac{i}{2} \xi [\phi_i, \bar{\phi}_i] + (F_{\mu\nu} + \frac{i}{2} C_{\mu\nu} \bar{\lambda} \lambda) \sigma^{\mu\nu} \xi, \quad \delta \bar{\lambda} = 0 \\
\delta \phi_i = \sqrt{2} \xi \psi_i, \quad \delta \bar{\phi}_i = 0 \\
\delta \psi_i = \xi \epsilon_{ijk} \phi^j \bar{\phi}^k, \quad \delta \bar{\psi}_{\dot{a}i} = -i \sqrt{2} \xi \epsilon^{\dot{a}a} \sigma^{\mu}_{\dot{a}a} D_\mu \bar{\phi}_i. \tag{16}
\]

We observe that upon the identification

\[
C_{\mu\nu} \epsilon_{ijk} = -\frac{\alpha'}{2\sqrt{2}} C_{\mu\nu ijk}, \tag{17}
\]

the bosonic terms linear in $C_{\mu\nu}$ of (15) match exactly to the Myers terms in (13). The conclusion is that the deformation of $N = 4$ SYM theory induced by the nonanticommutative star product correctly reproduces the Myers terms. This is a further support for taking (15) as the lagrangian of a stack of D3-branes in the five-form flux background.

It is interesting to compare the supersymmetric lagrangian (15) with the one constructed in [38]. In [38], a term quadratic in $C$ was added by hand just for supersymmetric completion. Although the quadratic $C$-terms in these two lagrangians look different, they are both supersymmetric by themselves. Except for this, the two lagrangians have the same bosonic part. The $C$-dependent fermionic parts and the supersymmetry transformations are totally different. For the supersymmetry transformations, in [38] a deformation of the kind $C_{\mu\nu ijk} \bar{\phi}^i \phi^j \bar{\phi}^k$ was introduced in $\delta \lambda$, whereas in (16) $\delta \lambda$ is deformed through the term $C_{\mu\nu} \bar{\lambda} \lambda$. So we conclude that the supersymmetric extension of the system is not unique. As for the supersymmetry transformations, the fixed points of the super charges are not the same. For the model constructed in [38], the fixed points do not change after the deformation with the RR flux. However, as we discuss in the next section, the fixed points of the supersymmetry transformations in (16) will be different.

To see which lagrangian originates from string theory, one needs to generalize and extend the Myers method to calculate the quadratic terms in the RR fields as well as the fermionic terms. However, as Seiberg, Ooguri and Vafa [2, 1] have pointed out, the nonanticommutativity arises if we turn on a graviphoton background (which in turn comes from a five-form flux upon compactification to four dimensions). Therefore, we expect a string theory calculations would yield (15) as the effective lagrangian of D3-branes in this RR background.

4 Vacuum States

In this section we will examine the vacuum states of the model. We first argue that the partition function of the model is independent of the deformation parameter $C$. 

This happens because the undeformed $\mathcal{N} = 4$ SYM theory has an exact $R$-symmetry. On the other hand, all the $C$-dependent terms which appear after the deformation have a positive $R$ charge, and hence they will have a zero expectation value in the undeformed theory. So we conclude that the partition function is invariant under the deformation. This further implies that the vacuum energy remains to be zero. This is similar to what happens in the Wess-Zumino model [42] and pure $\mathcal{N} = 1/2$ SYM theory [43]. Apart from ordinary vacuum states of $\mathcal{N} = 4$ SYM theory, in the following, we will see that the deformed theory admits more vacuum states. First we discuss a set of vacua which are invariant under the supersymmetry transformations. Besides such BPS vacua we also encounter zero energy configurations in which supersymmetry is spontaneously broken.

### 4.1 Supersymmetric vacua

To discuss the BPS states of the model, let us first set the fermions to zero and look at the bosonic configurations for which the variations of the fermionic fields vanish. So requiring $\delta \lambda, \delta \psi_i$, and $\delta \bar{\psi}_i$ to be zero we obtain

$$F_{\mu\nu}^+ = 0, \quad D_\mu \bar{\phi}_i = 0,$$

$$[\phi_i, \bar{\phi}_j] = 0, \quad [\bar{\phi}_j, \bar{\phi}_k] = 0,$$  

for the BPS configurations. These are the ordinary BPS states of $\mathcal{N} = 4$ theory, however, note that here $\phi_i$ and $\bar{\phi}_i$ are independent and the commutator $[\phi_i, \phi_j]$ has not been fixed by the supersymmetry transformations. Therefore, one can think of BPS states where $\phi_i$’s (satisfying equations of motion) are not commuting.

An interesting case where vacuum solutions of this kind can appear is when $F_{\mu\nu}^+$ is a nonvanishing constant. This is only possible if the instanton number vanishes and the fermionic field $\bar{\lambda}$ is turned on. To see this, first let us take $\bar{\lambda} \neq 0, \delta \lambda = 0$, which requires

$$F_{\mu\nu}^+ + \frac{i}{2} C_{\mu\nu} \bar{l} \bar{\lambda} = 0,$$  

(19)

for the BPS configuration. Here, however, we would like to discuss the zero action constant solutions of this equation. In the undeformed $\mathcal{N} = 4$ theory ($C = 0$), for a vacuum state we require both the action and the instanton number to vanish implying that $F_{\mu\nu}$ must be zero. But in the deformed theory, the extra $C$-dependent term in the instanton equation allows to have vacua where $F_{\mu\nu}$ is nonvanishing. In contrast with the instantons, however, these are not localized solutions.

For simplicity, let us take the $U(1)$ part of the gauge field and $\bar{l}$ to be the only nonzero components. A solution to Eq. (19) then is a constant $\bar{\lambda}$ and a constant field strength. As this is a vacuum state we further require its instanton number to be zero (for example, one can choose $F_{12}$ to be the only nonzero component of
the field strength). For this choice, though, we can take $\phi_i$ to be a constant too, $D_\mu \phi_i = \partial_\mu \phi_i = 0$, such that its equation of motion reduces to

$$[\phi_i, \phi_k, \bar{\phi}^j] = \frac{\sqrt{2}}{16} |C|^2 \epsilon_{ijk} \left( \frac{7}{3} \bar{\phi}^j \lambda^\alpha \bar{\phi}^i - \bar{\lambda}_a \bar{\phi}^i \bar{\lambda}^a \bar{\phi}^j + \bar{\phi}^j \lambda_a \bar{\phi}^i \bar{\lambda}^a \right), \quad (20)$$

where, in deriving the above equation we have used (19) and the fact that $[\bar{\phi}^j, \bar{\phi}^k] = 0$.

Further, since only the $U(1)$ part of the $\bar{\lambda}$ is nonzero and $\bar{\phi}_i$'s commute Eq. (20) simplifies to

$$[\phi_i, \phi_k, \bar{\phi}^j] = 0. \quad (21)$$

For this to be consistent with the Jacobi identity, we need in addition to require that

$$[\phi_i, \bar{\phi}_j] = 0. \quad (22)$$

One solution to (21) is of course $[\phi_i, \phi_j] = 0$. However, we can also have the following new solution:

$$[\phi_i, \phi_j] = i \alpha \epsilon_{ijk} \phi_k, \quad (23)$$

preserving the $SO(3)$ symmetry of the action. In general, we expect that the equations of motion fix the parameter $\alpha$. However, here $\alpha$ remains an arbitrary constant parameter of mass dimension one; it is a moduli parameter in the space of supersymmetric vacua.

Eq. (23) implies that the holomorphic coordinates $\phi_i$'s satisfy an $SU(2)$ algebra and hence take value on a fuzzy two-sphere. To summarize, turning on a graviphton background $C_{\mu \nu}$ gives rise to a new supersymmetric vacuum state characterized as follows:

$$F_{\mu \nu} + \frac{i}{2} C_{\mu \nu} \bar{\lambda}^4 \bar{\lambda} = 0,$$

$$[\phi_i, \phi_j] = 0, \quad [\bar{\phi}_i, \phi_j] = 0, \quad [\phi_i, \bar{\phi}_j] = i \alpha \epsilon_{ijk} \phi_k, \quad (24)$$

where the index 4 refers to the $U(1)$ part of the gauge group. As a typical solution one might take $\bar{\phi}_i$ to lie in the $U(1)$ subalgebra of $U(N)$, and the $\phi_i$ take value in the $SU(2)$ subalgebra of $SU(N)$. An interesting aspect of the above solution is that although it contains a constant nonvanishing field strength and noncommuting scalars it does have a zero action. Also note that this state is supersymmetric by construction, and one might expect that it is a direct consequence of the condition $S = 0$. However, notice that the action is not hermitian and therefore supersymmetry is not necessarily followed from the vanishing of the action. In the next subsection we will provide such an example where the vacuum state breaks the supersymmetry.

The above configuration of $\phi_i$'s is reminiscent of a BPS vacuum state in $\mathcal{N} = 1^*$ model. There the deformation is through the mass term, and one interprets the
configuration as a collection of $N$ D3-branes sitting on a fuzzy two-sphere [45]. From the supergravity side, the mass deformation is equivalent to turning on a 3-form flux in the bulk. The D3-branes, on the other hand, couple magnetically to this 3-form through the Chern-Simons term, and hence it resembles a 5-brane wrapped on a two-sphere with $N$ units of RR flux flowing out.

### 4.2 Non-Supersymmetric Vacuum States

There are yet more constant vacuum solutions which look like a fuzzy sphere and can be constructed if $F^4_{\mu\nu}$ is a nonvanishing constant. Although, these states have a zero action, surprisingly they turn out to break the supersymmetry. This is mainly because of the extra $C$-dependent terms in the action and the fact that the theory is defined on Euclidean space where the scalars $\phi_i$ and $\bar{\phi}_i$ are treated independently.

To start with, consider the simple case of constant bosonic fields with fermions set to zero. Let us first look at the $\phi_r$ equation of motion, it reads

$$[\phi_j, \phi_r], \bar{\phi}^j = i \sqrt{2} \epsilon_{ijk} C^\mu{}_{\nu} F^4_{\mu\nu} \bar{\phi}^i \bar{\phi}^j + \frac{|C|^2}{24} \epsilon_{imn} \epsilon_{rkl} \left\{ \bar{\phi}^m \bar{\phi}^k \bar{\phi}^l \bar{\phi}^i - \bar{\phi}^k \bar{\phi}^l \bar{\phi}^m \bar{\phi}^i + \bar{\phi}^l \bar{\phi}^m \bar{\phi}^n \bar{\phi}^i + \bar{\phi}^m \bar{\phi}^n \bar{\phi}^k \bar{\phi}^i - \bar{\phi}^i \bar{\phi}^m \bar{\phi}^n \bar{\phi}^k \right\}.$$  

Now choose the following ansatz for $\bar{\phi}_i$ and $\phi_i$

$$[\bar{\phi}_i, \bar{\phi}_j] = i \alpha \epsilon_{ijk} \bar{\phi}_k$$
$$[\phi_i, \phi_j] = 0,$$  

where $\alpha$ is a constant parameter to be fixed by the equation of motion. If we plug (26) into (25) we obtain

$$\alpha^3 = -4 \sqrt{2} \frac{C \cdot F}{|C|^2},$$

where $F_{\mu\nu}$ is a constant $U(1)$ field strength, and $C \cdot F \equiv C_{\mu\nu} F^{\mu\nu}$. Notice that $[C] = -1$, so that $\alpha$ has a mass dimension 1.

Since $\bar{\phi}_i$'s are $N \times N$ representations of the $SU(2)$ algebra (26), it follows that

$$\sum_i \bar{\phi}_i \phi_i = \frac{\alpha^2}{4} (N^2 - 1).$$

Using this we can calculate the lagrangian density for this classical configuration, where only $\bar{\phi}_i$ and the $U(1)$ connection are nonzero,

$$\mathcal{L} = -\frac{1}{4} \text{tr} F_{\mu\nu} F^{\mu\nu} + \frac{1}{6} N (N^2 - 1) \frac{(C \cdot F)^2}{|C|^2}.$$  

9
We now show that there are $U(1)$ connections for which this lagrangian density vanishes and thus the configuration represents a vacuum state. Setting (29) to zero, we get
\[
\frac{(C \cdot F)^2}{|F|^2|C|^2} = \frac{3}{2(N^2 - 1)},
\]
which has always a solution for $N \geq 2$. Of course, for a vacuum state we must further require $F_{\mu \nu}$ to have a zero instanton number. For example, let $F_{12}$ and $F_{13}$ be the only nonvanishing components of $F_{\mu \nu}$. For $C_{\mu \nu}$, take the nonzero components to be $C_{12} = C_{34}$, therefore the lagrangian (29) becomes
\[
\mathcal{L} = -\frac{N}{2} (F_{12}^2 + F_{13}^2) + \frac{1}{6} N(N^2 - 1) F_{12}^2.
\]
which vanishes for
\[
F_{13} = k F_{12},
\]
with
\[
k = \pm \sqrt{\frac{N^2 - 4}{3}}.
\]

In contrast to the ordinary $\mathcal{N} = 4$ SYM theory in which we must restrict to zero gauge field strength to discuss the vacua, here we can have vacuum configurations of constant $F_{\mu \nu}$ and $\bar{\phi}$. The $C$-dependent terms allow a cancellation between the contributions of these two fields so that we get a zero action. As $\bar{\phi}$'s are not commuting, this vacuum is not supersymmetric, though.

## 5 Conclusions

In this work we studied a deformation of $\mathcal{N} = 4$ SYM theory induced by nonanticommutative star product. We worked out the $C$-dependent terms and showed that the bosonic linear terms in $C$ can be identified with the Myers terms of a stack of D3-branes in a five-form RR flux. This provided a further support that a graviphoton background induces a nonanticommutativity on the worldvolume of the brane. So the dynamics can be described either directly by taking into account the Myers terms, or the background effects on the dynamics can be captured through the nonanticommutative star product. We also discussed classical vacuum states of the theory. In addition to the ordinary vacua of $\mathcal{N} = 4$ theory, the theory admits vacua where (anti)holomorphic scalars do not commute. This happened mainly because the $\phi$ and $\bar{\phi}$ in Euclidean space are treated as independent fields, and the fact that we were interested in preserving only the $Q$ supersymmetry. Furthermore, as the action is not hermitian, we can also have vacua which break supersymmetry.
