Abstract
In this paper, the behavior of precious metals and oil is examined using a fractionally integrated and cointegrated modeling approach. Using daily data from January 2015 to December 2020 and using both endogenous and exogenous structural breaks, we examine the behavior of the related series before and during the COVID-19 pandemic with the aim of investigating whether the degree of persistence has changed since the onset of COVID-19. We found that precious metals and oil exhibit long memory and are mean reverting regardless of the sample considered as the fractional parameter \( d < 0.5 \). However, when structural breaks are taken into consideration, an increase in persistence is found during the COVID-19 as compared to the period before it. In addition, the fractionally cointegrated vector autoregressive (FCVAR) model of Johansen and Nielsen (2010, 2012) is used to examine the existence of long-run relationship among precious metals and oil price. We find the integrated parameters at \( d < 0.5 \) for all samples except for the pre-COVID-19 sample. This highlights that the FCVAR is a better fit for the full sample and the COVID-19 and the COVID-19 pandemic period sub-samples, as the fractional parameter is \( d < 0.5 \) while the CVAR model is better fit for the pre-COVID-19 period where \( d > 0.5 \). Both cointegration techniques alongside the parameter stability tests lend support to the existence of a persistence and stable long-run relationships among the series irrespective of the sample period considered. Attendant policy recommendations for investors and policymakers are recommended.

Introduction
Initially, the COVID-19 pandemic emerged as a health epidemic in China, but the highly contagious virus quickly metamorphosed into an unparalleled global pandemic within 3 months. Governments employed aggressive steps to curb its spread. These include, among other measures, travel restrictions and the complete lockdown of industries and companies across the globe. Economies have been impacted by these disturbances, arising primarily from supply chain disruptions, declining demand, and with attendant effects on the financial sector. While the real effect of the outbreak is yet to be quantified, the COVID-19 pandemic has created a new economy that has produced a large amount of data that will allow practitioners and scholars to validate whether established relationships that held in the past are still valid considering the increase uncertainty generated by the pandemic Salisu et al. (2020).

Precious metals have always been considered leading indicators of inflation and key variables that transmit the outlook for monetary policy in an economy (Greenspan 1993). Consequently, the pro-cyclical behavior of the price of precious metals has highlighted their functions as stores of value and safe heavens that provide critical information on the direction of an economy. In addition, Balcilar et al. (2021) and Balcilar and Usman (2021) emphasize that the important role oil price plays in formulating an optimal monetary policy
especially in resource rich economies. The traditional view of precious metals is that they act as a haven against inflation and provide diversification benefits to investors during periods of high uncertainty1 (see Baur and Lucey 2010; Batten et al. 2010; Arouri et al. 2012; Gil-Alana et al. 2015a; Gil-Alana et al. 2015b). Thus, the motivation behind this study is to examine the behavior of precious metals and oil. This current study seeks to evaluate the persistence of the time series data under investigation. It is pertinent to state here that the persistence2 feature in a time series data measures how short-term shocks lead to permanent future changes (Gil-Alana et al. 2013). Understanding the past developments in the behavior of precious metals and oil is critical to anticipate future price changes.3 The movements in the price of precious metal and oil have implications in gauging the trends of the whole commodity market (Bildirici and Turkmen 2015). Furthermore, precious metals and oil have become vital source of revenue for a lot of countries especially resource-rich economies. Consequently, examining the behavior during the COVID-19 pandemic as compared to the period before it will help provide information on forecasting the respective series and their potential effects on commodity markets and world economic development. In addition, the persistence nature of a series may be transmitted to other macroeconomic indicators where the impact of shocks could be permanent or transitory.

Several papers have empirically examined the persistence of precious metals. Gil-Alana et al. (2015a) examine the persistence of five major precious metals (gold, silver, rhodium, palladium, and platinum) using a parametric and semi-parametric fractional integration framework that considers structural breaks in the series. They find an increase in the degree of persistence of precious metals. Arouri et al. (2012) also use parametric and semi-parametric techniques while using the AFRIMA-FIGARCH model to examine if the returns of gold, silver, platinum, and palladium prices exhibit long memory and consequently find strong evidence of long memory. Using a similar technique as Arouri et al. (2012), Kirkulak and Lkhamazhapov (2014) find evidence of dual long memory in spot series and a lack of long memory characteristic in future returns.

The COVID-19 pandemic has brought attention to the behavior of financial markets (e.g., Corbet et al. 2020; Ashraf 2020; Phan and Narayan 2020; Akhtaruzzaman et al. 2021, 2020; Al-Awadhi et al. 2020; Mishra et al. 2020; Salisu and Sikiru 2020; Salisu et al. 2020; Salisu and Vo 2020; Topcu and Gulal 2020; Zhang et al. 2020, among others). Salisu et al. (2020) and Salisu and Vo (2020) contend that the pandemic has increased the degree of uncertainty in financial markets. Ji et al. (2020) evaluate the haven properties of commodities, cryptocurrencies, foreign exchange, and gold against movements in equity prices finding soybean futures and gold remain robust as safe haven assets during the pandemic. Mensi et al. (2020) used an asymmetric multifractal detrended fluctuation approach and find that gold and oil markets have become inefficient during the pandemic and that the efficiency is sensitive to scales and market trends. Finally, Gil-Alana and Monge (2020) examine the persistence of oil price using a fractionally integrated approach in response to the COVID-194 pandemic. They find evidence of market efficiency prior to the crisis, with the oil market becoming inefficient when incorporating the data covering the crisis.

The goal of this paper is to examine the persistence of three major precious metals (gold, silver, and platinum) and oil using a fractional integration technique with the aim of investigating whether the degree of persistence has changed since the onset of COVID-19. We believe that studying the nature of the persistence of precious metals and oil prices at a time, where the world is facing the pandemic, would provide valuable information to investors, academic scholars, interested individuals, and most importantly the policymakers. If precious metals and oil exhibit long memory, this suggests that any shock will require a long horizon for the impact to dissipate, while the opposite holds for the case of short memory. Thus, an outcome of this paper will help specifically investors and policymakers to assess the risk associated with investment in precious metals and oil markets and possible strategies to take in presence of shocks, having understood the nature of the potential shocks facing these markets.5 Second, a test is carried out to determine whether precious metals and oil are fractionally cointegrated using the Fractionally Cointegrating VAR model proposed by Johansen and Nielsen (2012) using a time series daily frequency data between the periods 1st January 2015 and 24th December 2020 for gold, silver, platinum, and oil price (Brent) respectively. The benefit of the fractionally cointegrated vector autoregressive (FCVAR) model is that it allows for the possibility of fractional integration when testing cointegration among relationships as compared to the traditional cointegrating vector autoregressive (CVAR) model of Johansen (1996).

The contribution of this study is of twofold: empirical and methodological. Methodologically, results obtained show that

---

1 The financialization of commodities has exposed commodity prices to market-wide shock (see Cai et al. 2001; Tang and Xiong 2012).
2 Persistence can be measured using traditional unit root tests (e.g., Phillips and Perron 1988); however, unit root tests have low power when the degree of persistence is high and consequently leads to over-accepting the null hypothesis Caporale and Pittis (1999). In addition, traditional unit root tests have low power when the series are characterized by a fractional process (Diebold and Rudebusch 1991; Robinson 1994; and Ben Nasr et al., 2014).
3 The persistence of a series has implications for consumers, producers, policymakers, and portfolio managers.
4 For more literature on oil price and the COVID-19 pandemic, see Narayan (2020), Devpura and Narayan (2020), Akhtaruzzaman et al. (2020a, b), and Mugaloglu et al. (2021).
5 The nature of the shocks includes whether the series exhibits long or short memory and if the shocks to the series are transitory or permanent.
the integrated parameters \((d < 0.5)\) is less than 0.5 for all samples except for the pre-COVID-19 sample. Correspondingly, the LR statistics is significant for all samples with exception of the pre-COVID-19 sample. This highlights that the FCVAR is better fit for the full sample and the COVID-19 and the COVID-19 pandemic period sub-samples, as the fractional parameter is \(d < 0.5\) while the CVAR model is better fit for the pre-COVID-19 period where \(d > 0.5\). Both cointegration techniques alongside the parameter stability tests lend support to the existence of a persistence and stable long-run relationships among the series irrespective of the sample period considered. Empirically, we found a direct relationship between precious metals and oil prices; thus, precious metals respond and are sensitive to shocks to oil prices irrespective of the economic situations.

This study is organized as follows: “Introduction” presents the introduction, followed by research methodology in “Methodology.” “Data and preliminary analyses” presents and discusses the descriptive and empirical results, while “Conclusion and policy implications” concludes the study with attendant policy suggestions.

Methodology

The study applies a fractional integration technique, which suggests that the number of differences required to make a series stationary \(l(0)\) may be by order in a fractional form and may not necessarily take an integer value. Consequently, given a time series \(x_t\), the fractionally integrated model can be specified as follows:

\[
(1-L)^d x_t = \alpha + \gamma \text{Trend} + \varepsilon_t; \tag{1}
\]

\(d\) is any real value, and \(L\) is the lag operator \((Lx_t = x)\). \(x_t\) is the log return of the series in question that is integrated of order \(d\) and is represented by \(x_t \approx l(d)\) and \(\varepsilon_t \sim N(0, \sigma^2)\).

For all real \(d\), premised on its binomial expansion, the polynomial \((1-L)^d\) in Eq. (1) can be presented as follows:

\[
(1-L)^d = \sum_{j=0}^{\infty} \binom{d}{j} L^j = \sum_{j=0}^{\infty} \left( \frac{d}{j} \right) (-1)^j L^j
\]

\[
= 1 - dL + \frac{d(d-1)}{2} L^2 - \ldots\]

\[
\text{therefore,}
\]

\[
(1-L)^d \pi_t = x_t - dx_{t-1} + \frac{d(d-1)}{2} x_{t-2} - \ldots \tag{3}
\]

Hence, Eq. (1) can be presented as follows:

\[
x_t = \alpha + \gamma \text{Trend} + dx_{t-1} + \frac{d(d-1)}{2} Z_{t-2} - \ldots + \varepsilon_t \tag{4}
\]

Equation (4) is built to underscore the key role \(d\) also plays in the calculation of the degree of persistence in the series as it describes the amount of dependence of the series (Gil-Alana and Carcel 2020). Consequently, the higher the value \(d\), the higher will be the level of dependence between observations in the series and consequently a higher degree of persistence.

Based on the specification in Eq. (4), three results are possible depending on the value of \(d\). Firstly, if \(d = 0\), then \(x_t\) displays low-level persistence (i.e., “short memory”) and the autocorrelations decay in an exponentially fast manner with the series being termed \(l(0)\) or covariance stationary and validates the efficient market hypothesis (EMH). Secondly, if \(d\) falls within the range of \((0,0.5)\), then \(x_t\) is termed as long memory due to the high degree of associations between observations that are distant in time. However, this process is stationary and mean reverting. Thirdly, if \(d \geq 0.5\), then \(x_t\) is presumed to be non-stationary but mean reverting, and the EMH does not hold. In the long memory scenario, \(x_t\) can exhibit properties of mean or non-mean reversion processes based on the value of \(d\). If \(0.5 < d < 1\), then \(x_t\) is mean reverting, and any policy will have a temporary influence on the series. Finally, if \(d \geq 1\), then \(x_t\) is non-mean reverting, and any policy shock on the series will have a permanent effect on the series. The parametric method Sowell (1992), which involves a maximum likelihood estimator, is used for estimating the fractional differencing parameter \(d\).

In addition, using the FCVAR model of Johansen and Nielsen (2010, 2012), the long-run properties of precious metals and oil are considered in a multivariate setting. The FCVAR allows for a fractional process of order \(d\) that cointegrates to order \(d-b\). The model is a constructed based on Johansen’s (1995) CVAR model. From a policy viewpoint, if precious metals and oil prices are cointegrated, this will be that, any policy action aimed at a specific variable will also influence other series. Additionally, if the cointegration is fractional, the impact of policy on these variables will only disperse after long horizons. Using the CVAR model as baseline, suppose that \(x_t\) is a vector of \(l(1)\) time series of element \(p\), the error correction form of the CVAR model is presented as follows:

\[
\Delta x_t = \alpha \beta x_{t-1} + \sum_{i=1}^{k} \Gamma_i \Delta x_{t-i} + \varepsilon_t
\]

\[
= \alpha \beta L x_t + \sum_{i=1}^{k} \Gamma_i \Delta L^i x_t + \varepsilon_t \tag{5}
\]

The FCVAR being a derivative of the CVAR is arrived at by interchanging the \(\Delta\) and \(L\) in Eq. (5) with their fractional equivalents in Eq. (6):

\[
\Delta^d Z_t = \alpha \beta^d \Delta^{d-b} L_b Z_t + \sum_{i=1}^{k} \Gamma_i \Delta^d L^i_b Z_t + \varepsilon_t \tag{6}
\]

\[6\] For more detailed analyses of the different methods used to analyze fractional integration, see Robinson (1994) and Robinson (1995).
given that $\Delta^d$ is the term indicating fractional difference and $L_b = 1 - \Delta^b$ is the fractional lag operator. $\alpha$ and $\beta$ are the long-run parameters that are the most relevant for the study and are $p \times r$ matrices with $0 \leq r \leq p$. The rank $r$ is the co-fractional rank. Columns of $\beta$ comprise the $r$ co-fractional vectors, and $\beta'x_t$ are the cointegrating combinations. $\alpha$ represents the speed of adjustment towards equilibrium for each of the variables. $\Gamma = (\Gamma_1, \ldots, \Gamma_k)$ captures the short-run dynamics of the variables in the autoregressive augmentation (Nielsen and Popiel 2018). Given that CVAR is a distinct case of the FCVAR, the FCVAR model condenses to the CVAR variant if $d = b = 1$.

Data and preliminary analyses

The time series data used for analysis in this paper is of daily structure from 1st January 2015 to 24th December 2020 for gold, silver, platinum, and oil price (Brent). The data was sourced from Bloomberg. The results of the unit root test indicate that all the series are non-stationary. Table 1 contains the descriptive statistics for the data of the study. The full sample was split into the period before the occurrence of COVID-19 and after wave 1 of the occurrence of the pandemic. In addition to the exogenously determined breaks in the data, the presence of an endogenous structural break in the data is tested using the multivariate framework of Bai et al. (1998). A common break date in March 2020 is observed.

As revealed in Table 1, gold, silver, and platinum recorded higher mean values for the period during COVID-19 as compared to oil where it recorded lower mean values. In addition, the three categories of precious metals and oil were more volatile in the COVID-19 sample than in the pre-COVID-19 sample as can be seen from the higher standard deviation in the data. Following the descriptive analysis, Figure 1 reveals the graphical plots of the precious metals and oil prices with their returns respectively.

Results

Are precious metals and oil fractionally integrated?

For the EMH of Fama (1965) to hold, the series must be integrated of order zero (i.e., $d = 0$) and consequently follow a random walk process. However, for the strong form of EMH to be violated, it requires that the fractional integrated parameter ranges within $(0,0.5)$, where the series exhibits long memory (stationary) and shocks to the series dies out within a short

---

time frame for the weak form of EMH to hold. In the other scenario when the fractional parameter lies within the range of $0.5 < d < 1$ where the series exhibits long memory (non-stationary) with mean reversion, market inefficiency holds with the impact of shocks taking a long period to fizzle out, provided that the level of persistence is not permanent $d \geq 1$.

Table 2 presents the results of the fractionally integrated approach for the full sample under two scenarios: (i) an intercept and (ii) an intercept with a linear time trend. The results indicate the presence of long memory in the data as estimates of $d$ lie within the $(0,0.5)$ range and validate the presence of weak form efficient market hypothesis in the precious metals.

Fig. 1  Price and returns for gold, silver, platinum, and oil. Returns are computed as $\ln x_t - \ln x_{t-1} \times 100$. 
and oil markets. In addition, to strengthen the analysis, a Wald test is performed to check if shocks to series are transitionary or permanent. It was found that the impact that is similar across samples is temporary, fading over long horizons.

### Has COVID-19 changed the persistence of precious metals and oil?

Following the segmentation of data periods before the emergence of COVID-19, during COVID-19, and when COVID-19 was more pronounced as a pandemic (wave 1), an examination was carried out to see if the findings using the full sample were not biased by the option of sample periods used.

In a comparable routine to the full sample approach earlier, the persistence of the returns of precious metals and oil markets are examined using the fractionally integrated approach with an intercept and with intercept and a linear time trend in Table 3.

As with the full sample, precious metal and oil returns are found to be stationary and exhibiting long memory and mean reversion characteristics. However, of particular interest is how the degree of persistence has been increasing during the COVID-19 pandemic compared to the period before it. This could be attributed to an increase in uncertainty in financial markets because of the pandemic. As before, a Wald test was conducted to check if shocks to series are transitionary or permanent. It was found that the impact that is similar across samples is temporary, fading over long horizons.

### Are precious metals and oil fractionally cointegrated?

Having confirmed that precious metals and oil are fractionally integrated and exhibit long memory, the FCVAR model of Johansen and Nielsen (2010, 2012) was used to examine if cointegrating relationships are better formed in a fractional setting or using the conventional CVAR of Johansen (1995). To do this, the integrated parameter and corresponding Likelihood Ratio (LR) Static were checked to corroborate whether long-run relationships are better formed in the FCVAR than the CVAR. As a prelude, the optimal lag is determined under two scenarios: (i) a model with deterministic trend and (ii) a model without a deterministic trend with the maximum lag set at 5.

### Table 2: Estimates of $d$ using the full sample

| Metals     | Intercept | Intercept & trend | Intercept | Intercept & trend | Intercept | Intercept & trend |
|------------|-----------|------------------|-----------|------------------|-----------|------------------|

Note: Values in parentheses are standard errors of the associated $d$ coefficients, while values in the square brackets are the $p$-values. *** , ** , * represent 1%, 5%, and 10% levels of significance, respectively

The optimum lag was selected based on the Akaike information criterion (AIC) across the full sample and the remaining sub-samples as reported in Table 4. For the models excluding a deterministic trend, the AIC picks a lag of 2, 0, 3, and 0 for the full sample and the pre-COVID-19, COVID-19, and COVID-19 pandemic sub-samples, respectively. For the model including a deterministic trend, the AIC selects lags of 3, 3, 3, and 2 for the full sample and the pre-COVID-19, COVID-19, and COVID-19 pandemic sub-samples, respectively. The corresponding cointegration results are presented in Table 5. At different levels of significance for the model excluding deterministic trends, the null of no cointegration is rejected, for one cointegrating vector of the full sample and other sub-samples, respectively. For the model including a deterministic trend, the null of no cointegrating vectors for a maximum of 1, 2, 2, and 1 lag(s) for the full sample and the pre-COVID-19, COVID-19, and COVID-19 pandemic sub-samples, respectively. Consequently, this shows that precious metals and oil price returns are cointegrated irrespective of the sample period considered.

Note: $d$ represents the fractional parameter; the Likelihood Ratio is signified by $LR$. 

Table 6 presents the option between either the FCVAR or the conventional CVAR. The results obtained show the integrated parameters at $d < 0.5$ for all samples except for the pre-COVID-19 sample. Correspondingly, the LR statistics are significant for all samples with exception of the pre-COVID-19 sample. This highlights that the cointegrating relationships are better fit, using the fractional integration framework for the full sample and the COVID-19 and the COVID-19 pandemic.
period sub-samples, as the fractional parameter is $d < 0.5$ while the CVAR model is better fit for the pre-COVID-19 period where $d > 0.5$. To check for parameter stability, the roots of the characteristic polynomial are presented in Figs. 2, 3, 4, and 5, which clearly lend credence to the validity of the results, as it confirms that the parameters are stable.

**Conclusion and policy implications**

The behavior of precious metals and oil is examined using a fractionally integrated and cointegrated modeling approach. Using daily data from January 2015 to December 2020 and using both endogenous and exogenous structural breaks, it is found that precious metals and oil exhibit long memory and are mean reverting regardless of the sample considered as the fractional parameter $d < 0.5$. However, when structural breaks are taken into consideration, an increase in persistence is found during the COVID-19 as compared to the period before it. In addition, using the FCVAR model as advanced by Johansen and Nielsen (2010, 2012) to examine the existence of long-run relationship among precious metals and oil price, we find the integrated parameters at $d < 0.5$ for all samples except for the pre-COVID-19 sample. Correspondingly, the

| Period                  | Excluding deterministic trend | Including deterministic trend |
|------------------------|------------------------------|------------------------------|
|                        | $d$  | $LR$            | $d$  | $LR$            |
| Full sample            | 0.010 (0.000) | 768.935 [0.000] | 0.010 (0.000) | 292.401 [0.000] |
| Pre-COVID-19           | 1.282 (0.013) | 2.687 [0.174]   | 1.286 (0.012) | 1.896 [0.164]   |
| COVID-19               | 0.010 (0.041) | 120.24 [0.000]  | 0.010 (0.000) | 53.073 [0.000]  |
| COVID-19 pandemic      | 0.010 (0.031) | 549.937 [0.000] | 0.093 (0.020) | 112.238 [0.000] |

Note: $d$ represents the fractional parameter; the Likelihood Ratio is signified by $LR$.
LR statistics was found significant for all samples with exception of the pre-COVID-19 sample. This highlights that the fractional integration is better fit for the full sample and the COVID-19 and the COVID-19 pandemic period sub-samples, as the fractional parameter is $d < 0.5$ while the CVAR model is better fit for the pre-COVID-19 period where $d > 0.5$. Both cointegration techniques alongside the parameter stability tests lend support to the existence of a persistence and stable long-run relationships among the series irrespective of the sample period considered.

The persistence and stable long-run relationships confirmed between precious metals and oil prices irrespective of the sample periods considered have enormous empirical implications for nations that are endowed with precious metals and oil. Results show that precious metals respond to shocks to oil prices either positively or negatively. Hence, precious metals are sensitive to shocks to oil prices irrespective of the economic situations. The persistence and stable long-run relationships is an indication of a direct relationship between precious metals and oil prices. An increase in oil price stimulates...
inflation. As inflation increases, precious metals become a preferred and better-fit hedge against rising inflation. Comparatively, the prices of precious metal rise as general price level begin to rise, and vice versa. This finding resonates the study of Charlot and Marimoutou (2014) for the United States.

Understanding the relationship between precious metals and oil prices is significant for decision-making process, most especially when it comes to risk, production, and portfolio management. As oil prices increases, investment in precious metals becomes beneficial in terms of high returns to investors in the long run (Jain and Ghosh 2013). This implies that investment in precious metals can make an efficient portfolio, which diversifies risk and facilitates desirable risk adjust returns (Arif et al. 2019). It is paramount to mention that the direct relationships between oil and precious metals would out behind growth in manufacturing sectors, specifically when it comes to cost of purchasing precious metals and oil (Arif et al. 2019).

Conclusively, from a policy standpoint, we believe that investors should put their ears to the ground and eyes on the variations (fluctuations) noticeable with these commodities prices in terms of pattern and trend. Governments and investors should diversify their portfolio and invest more in precious metals to minimize future shocks to oil prices and capital loss due to fluctuation in oil price changes, thus guaranteeing maximum returns for investors and increase in foreign exchange earnings for the government. Policymakers on the other hand should enhance the share of previous metals as an asset reserve away from oil dependence. This policy should be put in place to halt domestic currency from losing its value and at the same depletion of nation foreign reserves.
