**Abstract.** New sensitive VLA observations confirm the existence of halo and relic sources in 6 Abell clusters where a diffuse emission was found in the NVSS.

We find evidence that the frequency of clusters with halos and relics is larger in clusters with high X-ray luminosity. The evidence that the occurrence of a halo source is larger at high redshifts is marginal.

1. **VLA observations**

In a recent paper, Giovannini, Tordi, & Feretti (1999) presented a sample of halo and relic cluster radio sources found in the NRAO VLA Sky Survey (NVSS, Condon et al., 1998). They used as cluster sample the X-Ray-brightest Abell-type clusters (XBACs) presented by Ebeling et al. (1996). The complete sample contains 177 clusters; some more clusters are present but do not belong to the complete sample because of their too low galactic latitude or too high redshift (larger than 0.2; see Giovannini, Tordi, & Feretti (1999) for a detailed discussion).

Six clusters where a central halo and/or a peripheral relic source was found for the first time, were observed by us with ~ 5 hrs long observations each, with the VLA in the C and D configurations. They are: A115, A520, A773, A1664, A2254 and A2744.

In all clusters the presence of the extended source was confirmed. The new results are in good agreement with NVSS data, confirming the very high reliability of the NVSS survey also for low brightness extended sources. The size of diffuse sources is larger in the new maps, as expected because of the better sensitivity reached in pointed observations.

Adding to the list given by Giovannini, Tordi, & Feretti (1999) all clusters where the presence of a halo and/or a relic source was reported in literature, we have a sample of ~ 40 cluster of galaxies with a diffuse source.
2. Frequency of halos and relics with the X-Ray luminosity

The number of new diffuse halos detected in the NVSS is rather high, especially considering that these sources are characterized by a steep spectrum and therefore that they are better imaged at frequencies lower than 1.4 GHz and also taking into account the limited surface brightness sensitivity.

We used these data to derive the occurrence of a diffuse source in clusters of galaxies of different X-ray luminosity. In Table 1 we report the results obtained for the complete sample (Col. 4) and the total sample (Col. 5). The X-ray luminosity is computed in the Rosat band (0.1 - 2.4 Kev).

| $L_x$ range (erg s$^{-1}$) | Cluster number | Source number | % | % adding the not complete sample |
|---------------------------|----------------|---------------|---|-------------------------------|
| $L_x \leq 3 \times 10^{44}$ | 79             | 2             | 3 | 2                             |
| $3 \times 10^{44} < L_x \leq 5 \times 10^{44}$ | 34             | 2             | 6 | 6                             |
| $5 \times 10^{44} < L_x \leq 7 \times 10^{44}$ | 22             | 2             | 9 | 9                             |
| $7 \times 10^{44} < L_x \leq 10^{45}$ | 31             | 9             | 29 | 27                           |
| $L_x > 10^{45}$ | 11             | 4             | 36 | 44                           |

The percentage of clusters with halos and relics increases with X-Ray luminosity. There is evidence that this increase is more relevant for central halo sources than for peripheral relic sources. The clusters hosting radio halos and/or relics have an X-Ray luminosity significantly higher than the other clusters (confidence level > 99.9% estimated with a Kolmogorov-Smirnov test).

3. Frequency of halos and relics with the redshift

To investigate if the frequency of diffuse sources depends on the redshift, we have considered only the 19 clusters with an X-ray luminosity $> 9 \times 10^{44}$ erg s$^{-1}$ which are always visible in the complete sample ($z \leq 0.2$). We find that 55% of clusters with $0.15 < z \leq 0.2$ have a diffuse source, to be compared with 33% of clusters with $0.044 \leq z \leq 0.1$. The difference is not statistically significant because the too small number of clusters; a deeper and larger sample is necessary to investigate this point.
