Introduction

Borderline ovarian tumors (BOTs) comprise 10-20% of ovarian malignancies (1). Although they are similar to malignant epithelial ovarian tumors in some of the histologic characteristics, these types of tumors do not have destructive stromal invasion (2). Their prognosis is much better than that of carcinoma (3). BOTs can be divided into serous, mucinous, endometrioid, clear cell, and Brenner types (4). Median age at diagnosis is 10-20 years younger than that of invasive ovarian cancer, and BOTs are usually diagnosed at an early stage (4, 5). Up to 30-50% of BOTs are mucinous (4). Mucinous BOTs (mBOTs) were classified into “intestinal” or “Mullerian” (endocervical) types. However, according to a new classification, endocervical mBOT is a part of seromucinous tumors and intestinal mBOT is accepted as mBOT (6). mBOTs are rarely associated with pseudomyxoma peritonei. However, 75% of tumors associated with pseudomyxoma peritonei have an appendiceal origin (7). In the past, guidelines often recommended removal of the appendix in patients with mBOT. However, appendectomy is controversial today, and some authors suggest appendectomy only if the appendix appears macroscopically abnormal (4). More than 90% of patients with mBOT have stage I disease, and fewer than 10% are bilateral (7).

The purpose of this study was to analyze the clinicopathologic features, recurrence and survival rates, reproductive history, and treatment of patients with mucinous borderline ovarian tumors (mBOTs).

Material and Methods

Patients with a diagnosis of mBOT were evaluated retrospectively. Patients with borderline ovarian tumors other than mucinous type and concomitant invasive cancer were excluded. A total of 75 patients were identified. Median age was 38 years. The most common symptom was pain (42.7%). Median CA-125 level was 23.5 IU/mL (range, 1–809 IU/mL). Median tumor size was 200 mm (range, 40-400 mm), and 6.7% of mBOTs were bilateral. Thirty-six (48%) patients underwent staging surgery. Two patients (5.9%) had nodal involvement. One patient received platinum-based adjuvant chemotherapy. One (1.3%) patient had recurrence. None of the patients died because of the ovarian tumor. A total of 43 patients had conservative surgery. Prognosis of mBOTs is excellent, and fertility-sparing surgery should be considered in the reproductive age group. Furthermore, the necessity of staging surgery is controversial. (J Turk Ger Gynecol Assoc 2016; 17: 96-100)
The treatment of patients with these tumors was altered during the period of research. The staging surgery was decided according to the time of the diagnosis of the tumor (intraoperatively vs postoperatively) and the opinion of the surgeon. For the premenopausal women who desire pregnancy, fertility-sparing surgery (conservative surgery) was preferred. Radical surgery (total abdominal hysterectomy and bilateral salpingooophorectomy) was done for women who are not willing to be pregnant again. Preservation of the uterus and minimum one ovary was performed for the fertility-sparing surgery. This description contains unilateral adnexectomy (UA), unilateral cystectomy (UC), UA with contralateral cystectomy (UA+CC), and bilateral cystectomy (BC), with or without staging surgery. All of the patients had laparotomy for surgery. Samples gained from surgery were assessed by pathologists who are skilled in gynecologic pathology. Seventy-five patients with mBOT were included in the study; 14 of these 75 patients were sent to our institution from other hospitals because of having mBOT. After the pathologic specimens were confirmed as BOT by our pathologists, we finalized the diagnosis of patients as BOT. For identification of BOT, World Health Organization (WHO) diagnostic norms were utilized. The criterion for being BOT is showing uncharacteristic epithelial proliferation lacking stromal invasion. Staging surgery was performed by using 1988 International Federation of Gynecology and Obstetrics (FIGO) staging system for ovarian carcinoma.

Patients were taken to abdominal ultrasonography, performed pelvic examination, CA-125 levels, blood biochemistry, and complete blood count every 3 months for 2 years, every 6 months till the fifth year, and once a year subsequently. If required, thoracic, abdominal, or pelvic computed tomography was performed. The time between the surgical treatment and the patients’ last visit was assessed as follow-up time. Time to recurrence was defined as the period between surgery and relapse.

Statistics
Data assessment was made by using the SPSS 11.5 for windows (SPSS Inc.; IL, USA). P values <0.05 were accepted as statistically significant.

Results
Clinicopathologic factors
A total of 250 patients having a final diagnosis of BOT between January 1990 and April 2014 in our institution were identified, of whom 175 with cell types other than mucinous were excluded. The remaining 75 patients had mBOT. Median age at diagnosis was 38 years (range, 16-77 years). Sixty percent of the patients were premenopausal, and 4% had a history of infertility. The most common symptom before diagnosis was pain (42.7%), and 25.3% of patients had sensation of bloating. The characteristics of the patients are shown in Table 1.

Preoperative CA-125 levels of 46 patients were known. Median CA-125 level was 23.5 IU/mL (range, 1-809 IU/mL). Eighteen patients had a CA-125 level above 35 IU/mL. Median tumor size was 200 mm (range, 40-400 mm). Only 6.7% of mBOTs were bilateral.

Stage I disease was observed in 45% and stage III only in 3% of patients. Among 75 patients, 43 (57%) had conservative surgery. Among these 43 patients, 34 had UA, 5 had UA+UC, 3 had UC, and 1 had BC. Staging surgery was not performed in 39 (52%) patients. Thirty-six (48%) patients underwent staging surgery. Eleven of these 36 patients had staging surgery at the second operation (re-staging). Among these 36 patients, 34 had lymphadenectomy. Median number of harvested lymph nodes was 52 (range, 21-105). These numbers were 36 (range, 21-67) and 19 (range, 0-38) for pelvic and para-aortic regions, respectively. Among the 34 patients, two (5.9%) had nodal involvement. One patient had pelvic and one had para-aortic involvement. Omentectomy was performed in 53% of patients, and omental metastasis was not detected in any of these patients. Appendectomy was performed in 44 (58.7%) patients, and none of the patients had involvement of the appendix. No other pathologic finding was detected in the appendectomy specimens. Abdominal cytology was reported in 47 patients of which five (6.7%) had positive cytology, reported as atypical cells. No patient was reported to have microinvasion or micro-papillary growth pattern. Only one patient received platinum-based adjuvant chemotherapy (Carboplatin flacon, 450 mg/45 mL; Eczacıbaşı, Turkey). Reason of adjuvant therapy was nodal involvement in this patient. None of the patients had adjuvant radiotherapy. Median follow-up time was 51 months (range, 1-222 months). The clinical features and the type of the operations are shown in Table 2.

Recurrence and survival
Median follow-up time was 51 months (range, 1-222 months). Only one (1.3%) patient had recurrence. None of the patients died because of the ovarian tumor. The patient with recurrent
Table 2. The pathologic and surgical characteristics of patients, n=75

| Characteristics                  | Median (range), n (%) |
|----------------------------------|-----------------------|
| Mean tumor size (mm)             | 200 (40-400)          |

UA: unilateral adnexectomy; UA+CC: unilateral adnexectomy+contralateral cystectomy; UC: unilateral cystectomy; BC: bilateral cystectomy; TAH+BSO: total abdominal hysterectomy+bilateral salpingo-oophorectomy; BA: bilateral adnexectomy

mBOT had recurrence twice: her first recurrence was after 61 months following the first surgery and the second recurrence was 91 months after first surgery. She had right unilateral salpingo-oophorectomy (USO) in the first operation conducted in another institution. Preoperative CA-125 level was unknown. Resurgery for staging had not been performed. She had left ovarian cystectomy after both the first and second recurrences. Both pathology results revealed mBOT. She has been free of disease for 116 months after the second recurrence, and she had a term pregnancy after her second recurrence.

Reproductive history
A total of 43 patients had conservative surgery in the first operation. Median age of these patients was 29 years (range, 16-40 years). Among these patients, desire for pregnancy was reported in the files of 14 patients. In all, 12 patients got 14 pregnancies. Eleven pregnancies went to term, 1 pregnancy terminated with abortion, and the pregnancy outcomes of 2 patients were not known.

Discussion
BOTs constitute 10-20% of ovarian malignancies (1), and 30-50% of BOTs are mucinous (4). In the literature, there is limited data evaluating only mBOTs. We retrospectively analyzed patients with mBOT.
the ovary did not have lymph node metastases. A review from Italy, which was about early stage BOTs, included 15 studies—a total of 948 cases—and showed that 69 (6%) patients had stage I disease, 10.3% had stage II, 19.2% had stage III, and 0.6% had stage IV (17). However, this study included patients with all types of BOT, not only mBOTs. These ratios were for both serious BOTs and mBOTs. Romagnolo et al. (18) compared the laparoscopic and laparotomic approach in patients with BOT. They found that in 35 patients with mBOT, 34 patients had stage I disease. Brown and Frumovitz (14) reported that in three series that included 146 patients with mBOT, none had lymphatic metastases. Kleppe et al. (4) investigated the incidence of mucinous neoplasm in the appendix in patients with mBOT and found that appendices of 13 patients with mBOT were removed and all of them were microscopically normal. Our findings were similar to the literature. Our results showed that staging surgery was performed in 48% of patients and that only 3% of patients had stage III disease. Among 34 patients who had lymphadenectomy, only 2 had nodal involvement. Omental metastases, peritoneal implants, involvement of the appendix, microinvasion, or micropapillary growth pattern were not seen in any of these patients.

One patient received platinum-based adjuvant chemotherapy (Carboplatin-flacon, 450 mg/45 mL; Eczacıbaşı, Turkey). The reason of adjuvant therapy was nodal involvement in this patient. None of the patients had adjuvant radiotherapy. Only one (1.3%) patient had recurrence. None of the patients died due to the ovarian tumor. Our results showed that the prognosis of patients with mBOT was excellent. We did not compare the survival and recurrence rate between staged and unstaged patients, as no patients died because of mBOT and only one patient had recurrence. Winter et al. (19) compared the survival and recurrence rate between staged and unstaged patients with all types of BOT. They showed that there was no difference between staged and unstaged patients. In a retrospective study that aimed to show the prognostic importance of each step of the surgical staging in patients with serious BOT reported that by each skipping step of the surgical staging the recurrence risk of the patient increased (20). Trillsch et al. (21) analyzed the age-dependent differences in patients with all types of BOT and point out that younger patients had higher disease recurrence risk. It is known that BOTs are usually seen in young women, and these patients may have desire for pregnancy. In the present study, median age of patients who had conservative surgery was 29 years. In many other studies, it was said that conservatively treated patients may have desire for pregnancy. In the present study, the median age of patients who had desire for pregnancy was 29 years. In our series, desire for pregnancy was reported in the files of 14 patients. We did not calculate the pregnancy rate, since we did not know whether the remaining 61 patients had desire for pregnancy. Our study is a retrospective study. Furthermore, it does not compare survival and recurrence rates, and not calculate the pregnancy rates. One should consider these limitations in assessing our findings.

In conclusion, as prognosis of patients with mBOT is excellent, fertility-sparing surgery should be considered in the reproductive age group. Furthermore, the necessity of staging surgery is controversial, since mBOT is a clinically benign tumor.
