Presynaptic N-type voltage-gated Ca\(^{2+}\) channels (Cav2.2) form part of an extensive macromolecular complex in the presynaptic terminal. Regulation of Cav2.2 is achieved via protein-protein interactions within the terminal and can directly impact transmitter release which is dependent on Ca\(^{2+}\) influx via these Cav2.2. We recently identified a novel Cav2.2 interacting partner—the collapsin response mediator protein (CRMP). CRMPs are a family of five proteins implicated in signal transduction of neurite outgrowth and axonal guidance. We showed that CRMP-2, a well-studied member of this family, interacted with Cav2.2 via direct binding to cytoplasmic loops of Cav2.2. Depolarization enhanced the interaction. Further studies revealed that CRMP-2 facilitated an increase in Cav2.2 current density by inserting more Cav2.2 at the cell surface. As a consequence of CRMP-2-mediated increase in Ca\(^{2+}\) influx, release of the excitatory neurotransmitter glutamate was also increased. CRMP-2 localized to synapses where, surprisingly, its overexpression increased synapse size. We hypothesize that the CRMP-2-calcium channel interaction represents a novel mechanism for modulation of Ca\(^{2+}\) influx into nerve terminals and, hence, of synaptic strength. In this addendum, we further discuss the significance of this study and the possible implications to the field.

Key words: axonal outgrowth, CRMP-2, growth cone, presynaptic calcium channels, surface trafficking, Cav2.2, synaptic transmission

Cav2.2 within hippocampal neurons. Traditional in vitro binding experiments and isothermal titration calorimetric analyses (Khanna M, Brittain JM and Khanna R, unpublished data) mapped the site interaction to two domains within the cytoplasmic loops of Cav2.2. The CRMP-2-Cav2.2 interaction is dynamic as KCl-induced depolarization led to an increase in the interaction. Functionally, these interactions led to an increased cell-surface expression of Cav2.2 and subsequent increase in Cav2.2 current density in hippocampal neurons. The CRMP-2-Cav2.2 interaction also resulted in an increase in the release of the excitatory neurotransmitter glutamate presumably through the increase in Ca\textsuperscript{2+} influx as toxin block of Cav2.2 eliminated this increase. As summarized in Figure 1, these results suggest CRMP-2 is a novel regulator of Ca\textsuperscript{2+} channel function and of transmitter release.

While our findings extend the biological functions of CRMP-2 past axon dynamics to include regulation of channel function and modulation of downstream transmitter release, they also raise important points for further discussion including the unexplored role(s) of related CRMPs in Ca\textsuperscript{2+} channel regulation, the nature of the oligomeric state of CRMPs to which Cav2.2 binds, whether post-translational modifications like phosphorylation can regulate the interaction and downstream effects, and the role CRMP-2-Cav2.2 interaction may play at the presynapse (i.e., growth cone). We consider these points in the following sections:

**Do other CRMPs (i.e., besides CRMP-2) influence Ca\textsuperscript{2+} channel function?** The five members of the CRMP family share ~65% sequence homology. High resolution crystal structures of CRMP-1 and -2 have been solved, and homology modeling of CRMP-3 and -4 reveals a very high degree of structural conservation. Based on the high sequence similarity between CRMP-2 and -4, their similar pattern of expression during development, and the reported interaction between CRMP-4 and proteins involved in synaptic vesicle recycling, we hypothesized that CRMP-4 may regulate Ca\textsuperscript{2+} channels. To test this hypothesis, we expressed CRMP-4a—a
Biochemical studies have demonstrated Ca²⁺ channel density. Whether this regulation results from altered channel biogenesis, trafficking, or stabilization remains to be investigated.

Oligomerization status of CRMP-2's interaction with Cav2.2. Structural and biochemical studies have demonstrated that CRMPs exist as tetramers. Tetramer formation is stabilized by the presence of divalent cations, whereas in the presence of cation chelating agents almost half of CRMP-2 exists in a monomeric state. While we have not directly tested whether Cav2.2 binds to a tetrameric or monomeric form of CRMP-2, the latter is a more likely possibility given the presence of chelators in our binding assay buffers. If, however, CRMP tetramers bind Cav2.2, then the subunit composition of the tetramer will be an important determinant of its effect on Cav2.2. The composition of CRMP tetramers will vary due to the differential spatial and developmental patterns of CRMPs expression within the nervous system. Thus, CRMPs, by virtue of their ability to heteromultimerize in multiple combinations, may help in ‘fine tuning’ the effects on Ca²⁺ channel density, thereby adding another level of complexity in transmitter release regulation. This oligomeric assembly of CRMPs may also serve as the building blocks upon which presynaptic signaling complexes are erected.

Does CRMP phosphorylation affect interaction with and regulation of Ca²⁺ channels? CRMP-2 is a multi-phosphorylated protein in neurons. CRMP-2 phosphorylation is regulated by several kinases, such as GSK-3β, Cdk5 and Rho kinase. Phosphorylation by GSK-3β and/or Rho kinase lowers the ability of CRMP-2 to interact with tubulin which leads to arrest of axonal growth and collapse of growth cones. While we have not directly tested whether Cav2.2 binds to the phosphorylated or non-phosphorylated state of CRMP-2, it is likely that, like tubulin, Cav2.2 binds to the non-phosphorylated but active form of CRMP-2. Cav2.2 and tubulin binding to the active form of CRMP-2 in the growth cone are entirely consistent with the roles served by these proteins at these locations—Ca²⁺ influx/synaptic transmission and axon growth, respectively. A recent study demonstrated that the CRMP-2 priming kinase Cdk5 also phosphorylates the adaptor protein Ca²⁺/calmodulin-dependent serine protein kinase (CASK). CASK binds to voltage-gated Ca²⁺ channels; it was recently shown that Cdk5 phosphorylation of CASK frees it to interact with presynaptic proteins including Cav2.2. As Cdk5-mediated phosphorylation of CASK increased Ca²⁺ currents via Cav2.2 channels, it is possible that Cdk5 affects Cav2.2 indirectly by modulating CRMP-2 phosphorylation and thus Cav2.2 activity. Besides these reports, the issues of phosphorylation-dependent effects of CRMPs on Ca²⁺ channel function are still largely unknown.

**Possible roles of the CRMP-2-Cav2.2 interaction at the pre-synapse (i.e., the growth cone).** Our study points to a novel role of CRMP-2 in regulating trafficking of Ca²⁺ channels and surprisingly, to synapse size. The latter results suggest a putative involvement of CRMPs in synapse formation and maintenance. Whereas the role of intracellular Ca²⁺ in growth cone activity and behavior have been well established, the involvement of the CRMP-2-Cav2.2 interaction in these events is unknown. One could speculate that the CRMPs may be responsible for transporting Cav2.2 into growth cones especially during synaptogenesis. In support of this idea, we observed robust colocalization between CRMP-2 and Cav2.2 co-localize within growth cones in dorsal root ganglion neurons. In another study, it was reported that the auxiliary Cavβ subunit was absent from the periphery of growth cones and filopodia in immature neurons. This is surprising given that Cavβ subunits are considered to be an obligatory component of the Ca²⁺ channel complex and are believed to associate with Cavα subunits very early during their biogenesis. Therefore, it is possible that CRMP-2, not Cavβ, is important for supplying nascent growth cones with a complement of highly motile Ca²⁺ channel α subunits. The CRMP-2-Cav2.2 complex is also likely to contribute to axon growth as well as to growth cone dynamics.
In summary, we have shown that the CRMP-2-Ca\(^{2+}\) channel complex may serve multiple purposes in neurotransmitter release: (1) to sustain Ca\(^{2+}\) influx through functional regulation of Ca\(^{2+}\) channels; (2) to target the N-type Ca\(^{2+}\) channel to immature synapses during synaptogenesis; (3) to provide a scaffold for the Ca\(^{2+}\) channel macromolecular complex; and (4) to recruit synaptic vesicles to Ca\(^{2+}\) channels. Thus, our results identify CRMP-2 as a novel ‘neuromodulator’ of Ca\(^{2+}\) channels and of synaptic strength. It will be interesting to examine if dysregulation of CRMP-2 expression and the CRMP-2-Cav2.2 interaction may contribute to diseases of synaptic function or ‘synaptopathies’.

Acknowledgements

CRMP4\(\alpha\) cDNA was a gift of Dr. Alyson Fournier (Montreal Neurological Institute, Montreal, Canada). We thank Drs. Gerry Oxford and May Khanna and Lisa D. King and Brian W. Jarecki for critically reading the manuscript.
