A NOTE ON SPACES OF ASYMPTOTIC DIMENSION ONE

KOJI FUJIWARA AND KEVIN WHYTE

Abstract. Let $X$ be a geodesic metric space with $H_1(X)$ uniformly generated. If $X$ has asymptotic dimension one then $X$ is quasi-isometric to an unbounded tree. As a corollary, we show that the asymptotic dimension of the curve graph of a compact, oriented surface with genus $g \geq 2$ and one boundary component is at least two.

Introduction

Our main results show that, under fairly weak restrictions, a geodesic metric space of asymptotic dimension one is quasi-isometric to a tree. Before stating precise results we review some definitions.

If $X$ is a set and $X = \bigcup_i O_i$ a covering, we say that the multiplicity of the covering is at most $n$ if any point $x \in X$ is contained in at most $n$ elements of $\{O_i\}_i$.

Recall that the covering dimension of a topological space $X$ is the minimal $d$ such that every open covering has a refinement with multiplicity at most $d + 1$. The notion of asymptotic dimension is a coarse analogue introduced by Gromov in [Gr93]:

Let $X$ be a metric space, and $X = \bigcup_i O_i$ a covering. For $D \geq 0$, we say that the $D$-multiplicity of the covering is at most $n$ if for any $x \in X$, the closed $D$-ball centered at $x$ intersects at most $n$ elements of $\{O_i\}_i$. The multiplicity is exactly the $0$-multiplicity.

The asymptotic dimension of the metric space $X$ is at most $n$ if for any $D \geq 0$, there exists a covering $X = \bigcup_i O_i$ such that the diameter of $O_i$ is uniformly bounded (i.e. there exists $C$ such that for all $i$, $\text{diam} O_i \leq C$), and the $D$-multiplicity of the covering is at most $n + 1$. We say that the asymptotic dimension of $X$, $\text{asdim } X$, is $n$ if the asymptotic dimension of $X$ is at most $n$, but it is not at most $n - 1$. If such $n$ does not exist, then we define the asymptotic dimension of $X$ to be infinite.

It is easy to see that if two metric spaces are quasi-isometric, then they have the same asymptotic dimension. A geodesic metric space has asymptotic dimension zero if and only if it is bounded. Since unbounded trees

have asymptotic dimension one, all spaces quasi-isometric to unbounded trees also have asymptotic dimension one, [Gr93].

Let $X$ be a geodesic metric space. We say $H_1(X)$ is \textit{uniformly generated} if there is an $L > 0$ so that $H_1(X)$ is generated by loops of length at most $L$.

**Theorem 0.1.** Let $X$ be a geodesic metric space with $H_1(X)$ uniformly generated. If $X$ has asymptotic dimension one then $X$ is quasi-isometric to an unbounded tree.

**Remark:** This theorem relies on a result of Manning ([Man]) characterizing spaces quasi-isometric to trees, see Theorem 1.2. The restriction on $H_1(X)$ is essential, see example 1.4.

Let $G$ be a finitely generated group, and $\Gamma$ the Cayley graph with respect to a finite generating set. Since the asymptotic dimension is invariant by quasi-isometry, the asymptotic dimension of $G$, $\text{asdim} G$, is defined to be the asymptotic dimension of $\Gamma$.

**Corollary 0.2.** Let $G$ be a finitely presented group. The asymptotic dimension of $G$ is one if and only if $G$ contains a non-trivial free group as a subgroup of finite index.

We are informed by Dranishnikov that this has been known [JS] (cf. [Ge], [D]). The assumption that $G$ is finitely presented is necessary. The following example is due to Osin.

**Example 0.3.** Let $G = A \wr \mathbb{Z}$ be the wreath product such that $A$ is a non-trivial finite group. Then, $\text{asdim} G = 1$ but $G$ does not contain a free group as a subgroup of finite index. $G$ is finitely generated, but not finitely presented.

By definition, $G$ is the semidirect product of $A^\mathbb{Z}$ and $\mathbb{Z}$, $A^\mathbb{Z} \rtimes \mathbb{Z}$, such that the action of $\mathbb{Z}$ is the obvious action of shifting the indexes of the direct product, $N = A^\mathbb{Z}$, of countable copies of $A$. There is an exact sequence $1 \to N \to G \to \mathbb{Z} \to 0$. Note that $N$ is a locally finite (i.e. any finitely generated subgroup is finite) countable group, which is not finitely generated. Therefore $G$ does not contain a free group as a subgroup of finite index. We want to show that $\text{asdim} G = 1$. Indeed, the notion of asymptotic dimension is extended to a countable group, and it is shown that $\text{asdim} G = \sup \text{asdim} F$, where sup is taken over all finitely generated subgroups $F < G$. [DS]. Since $N$ is locally finite, $\text{asdim} N = 0$. The Hurewicz type formula for asymptotic dimension is also extended, [DS], and we get $\text{asdim} G \leq \text{asdim} N + \text{asdim} \mathbb{Z} = 1$. Also, since $\mathbb{Z} < G$, $1 \leq \text{asdim} G$. It is easy to see that if $K$ and $L$ are finitely generated, then the wreath product $K \wr L$ is finitely generated. If both $K, L$ are finitely presented, $K \wr L$ is finitely presented if and only if $K$ is trivial or $L$ is finite, [Ba]. Therefore, $G$ is finitely generated, but not finitely presented.

It is natural to ask the following question:

**Question 0.4.** Suppose $G$ is a finitely generated group which is torsion free. If $\text{asdim} G = 1$, then is $G$ a free group?
Corollary 0.5. Let $X$ be geodesic metric space which is Gromov hyperbolic. If $X$ has asymptotic dimension one then $X$ is quasi-isometric to an unbounded tree.

This result does not require that $X$ be proper. One important class of examples which are not proper are curve complexes. Let $S = S_{g,p}$ be a compact, orientable surface such that $g$ is the genus and $p$ is the number of the connected components of the boundary of $S$. We assume that $3g−4+p >0$. The curve complex of $S$, defined by Harvey [Ha], are the flag complexes with 1-skeleton the curve graph of $S$, $C(S)$. The curve graph is the graph whose vertices are isotopy classes of essential, nonperipheral, simple closed curves in $S$, with two distinct vertices joined by an edge if the corresponding curves can be realized by disjoint curves. We remark that the curve complex of $S$ is quasi-isometric to the curve graph of $S$, so that they have same asymptotic dimension.

Masur and Minsky [MaMi] show the remarkable result that $C(S)$ is Gromov hyperbolic.

It is known that $C(S)$ has finite asymptotic dimension ([BeF]). Since $C(S)$ is unbounded it cannot have asymptotic dimension zero. No upper bound or non-trivial lower bound is known in general. In the case $p = 1$, Schleimer shows in [Sch] that $C(S)$ is one-ended, from which it follows that it is not quasi-isometric to a tree. Thus we can improve the lower bound on asymptotic dimension here:

Corollary 0.6. Let $S$ be a compact, oriented surface with genus $g \geq 2$ and one boundary component. Let $C(S)$ be the curve graph of $S$. Then the asymptotic dimension of $C(S)$ is at least two.

Acknowledgements. The first author would like to thank Greg Bell for discussion. We appreciate comments and information by Alexander Dranishnikov. We are grateful to Denis Osin, who shared his ideas with us.

1. Proofs

Theorem 0.1 follows from two key ingredients. The first is the classical argument that surfaces have covering dimension two (see, for instance, [Mu], section 55). The fact we need is the following:

Lemma 1.1. Let $S$ be a compact surface with boundary $S^1$. Let $A, B,$ and $C$ be points on $\partial S$, dividing it into arcs $AB$, $AC$, and $BC$. If $\{O_i\}_i$ is an open cover of $S$ with multiplicity two then there is some $i$ for which $O_i$ intersects all three segments $AB$, $AC$, and $BC$.

The second ingredient is a characterization of spaces quasi-isometric to trees due to Manning:

Theorem 1.2 (Th 4.6 [Man]). Let $Y$ be a geodesic space. Suppose that there exists a constant $K$ with the following property:
let $a, b$ be points in $Y$, $\gamma$ a geodesic from $a$ to $b$, and $\alpha$ a path from $a$ to $b$. Then the $K$-ball at the midpoint $m$ of the geodesic $\gamma$ has non-empty intersection with $\alpha$.

Then $Y$ is quasi-isometric to a simplicial tree.

We now prove Theorem 0.1:

**Proof.** The following lemma, essentially contained in [BW], explains the role of the uniform generation assumption:

**Lemma 1.3.** Let $X$ be a complete geodesic metric space. The following are equivalent:

- $X$ has uniformly generated $H_1$.
- $X$ is quasi-isometric to a complete geodesic metric space, $Y$, with $H_1(Y) = 0$.

(These are also equivalent to the condition $H_1^{uf}(X) = 0$ which is the form which appears in [BW].)

**Proof.** Let $Y$ be a complete geodesic metric space with $H_1(Y) = 0$, and let $f : X \to Y$ be a $(K, C)$-quasi-isometry. Suppose $l$ is any loop in $X$. Divide $l$ into segments $[a_0, a_1], [a_1, a_2], \ldots, [a_{n-1}, a_n]$, where $a_0 = a_n$ and the length of each segment is at most 1.

Let $b_i = f(a_i)$. We have $d(b_i, b_{i+1}) \leq K + C$. For each $i$ choose a geodesic segment in $Y$ connecting $b_i$ to $b_{i+1}$. Call the resulting loop $l'$. By assumption, $l'$ bounds, so we have $l' = \partial S$ for some surface $S$ mapping to $Y$. Triangulate $S$ so that the image of each simplex has diameter at most 1 in $Y$. For each vertex $v$ in $S$ let $\alpha(v)$ be a point of $X$ which maps close to the image of $v$ in $Y$. For each edge $e$ of $S$ with endpoints $u$ and $v$, choose a geodesic segment, $\alpha(e)$, in $X$ connecting $\alpha(u)$ to $\alpha(v)$.

Thus we have $\alpha$ mapping the one-skeleton of $S$ to $X$. For each simplex $\sigma$ of $S$ we have a loop in $X$ of length at most $D$ (depending only on $K$ and $C$). The boundary component of $S$ is mapped to a loop $l''$ which is within Hausdorff distance $D$ of $l$. The map $\alpha$ exhibits that $l''$ is a sum of classes of length at most $D$, and the condition on Hausdorff distance implies the same for $l - l''$. Thus $l$ is a sum of loops of length at most $D$, proving that $H_1(X)$ is uniformly generated.

Conversely, suppose $H_1(X)$ is generated by loops of length at most $D$. Let $A$ be a maximal collection of points in $X$ with $d(a, a') \geq D$ for all $a \neq a'$. Let $R = 3D$, and let $Y$ be the space:

$$X \cup_{a \in A} cone(B(a, R))$$

In words, $Y$ is $X$ with each $R$-ball centered at $a \in A$ coned to a point. We give $Y$ the induced path metric where each cone line has length $R$. The inclusion of $X$ is then isometric, and has coarsely dense image, and so is a quasi-isometry. By construction, any loop $l$ in $X$ of length at most $D$ is
Theorem 0.1 does not hold without the assumption on $H$ and $n$

Example 1.4. Let $X$ be a graph with vertex set $\mathbb{N}$ and two edges connecting $n$ and $n+1$, both of length $2^n$. Thus $X$ is a string of circles of increasing radii, each touching the next at a single point. It is clear that $H_1(X)$ is
not uniformly generated and in particular that $X$ is not quasi-isometric to a tree.

For any $D > 0$, choose $n$ such that $2^n \gg D$. Let $U$ be the union of the vertices $\{1, 2, \ldots, n\}$ of $X$ and all adjacent edges except for the $\frac{1}{2}D$-ball around the vertex $n + 1$. For $i > 0$ let $A_i$ be the ball of radius $D$ around the vertex $n + i$, let $B_i$ and $C_i$ be the subsets of the two edges from $n + i$ to $n + i + 1$ not within $\frac{1}{2}D$ of a vertex. It is easy to see that collection $\{U, A_i, B_i, C_i\}$ is a covering of $X$ with $D$-multiplicity two. By subdividing the $B_i$ and $C_i$ to a collection of intervals of length $2D$ covering each, one gets a covering with $D$-multiplicity by sets of diameter at most $2^n$. Thus $X$ has asymptotic dimension one.

Proof of Cor 0.2. A well known corollary of work of Stallings (Sta68) and Dunwoody (Dun85) is that a group quasi-isometric to a tree is virtually free. Thus corollary 0.2 follows immediately from Theorem 0.1 since the fundamental group of the Cayley graph is generated by translates of the relators, and so is generated by loops of length at most the length of the longest relator.

Remark: In fact, we get something a priori stronger: if $\Gamma = \langle F | R \rangle$ where $R_{ab}$ is a finitely generated $\Gamma$-module and $\Gamma$ has asymptotic dimension one then $\Gamma$ is virtually free. However, since every virtually free group is finitely presented, this does not include any new examples.

Proof of Cor 0.5. To prove Corollary 0.5 we need to check that $H_1(X)$ is uniformly generated. For any graph $G$ we have that $H_1(G)$, and, indeed, $\pi_1(G)$, are generated by isometrically embedded loops. If we divide such a loop into three equal pieces we get a geodesic triangle whose sides come close only at the corners. If $G$ is $\delta$-hyperbolic, this implies any such loop can have length at most $6\delta$, which proves the corollary.
