Abstract

AIM: This prospective study was designed to evaluate the changes in left ventricular (LV) systolic function after coronary artery bypass grafting (CABG) in patients with both normal and abnormal pre-operative systolic function.

METHODS: During the period from October 2017 to October 2018, forty-seven consecutive patients undergoing CABG were enrolled in this prospective study. Thoracic echocardiography was performed within 1 week before CABG as well as 4 to 6 months after surgery. All measurements were made by a single experienced investigator.

RESULTS: While the mean LV ejection fraction (LVEF) showed neither improvement nor significant reduction in the whole group of patients following CABG (from 54.21 ± 15.36 to 53.66 ± 11.56%, p = 0.677), significant improvement in LVEF was detected in the subgroup of patients with pre-operative LV dysfunction (from 40.05 ± 8.65 to 45.85 ± 9.04%, p = 0.008). On the other hand, there was a significant decline in LVEF in the subgroup of patients with normal pre-operative LVEF (from 64.70 ± 9.72 to 59.44 ± 9.75%, p = 0.008). As for the other parameters of systolic function, significant decrease in LV end-diastolic volume index (LVEDVI) (p = 0.001), LV end-systolic volume index (LVESVI) (p = 0.0001), wall motion score index (WMSI) (p = 0.013) and LV mass index in male patients (p = 0.011) was shown only in patients with decreased LVEF after CABG. Patients with improved postoperative LVEF (53.2% of all patients) had significantly lower baseline LVEF (p = 0.0001), higher LVEDVI (0.009) and higher WMSI (p = 0.006) vs patients with worsened postoperative LVEF (38.3% of all patients).

CONCLUSION: Our study showed that LVEF, internal basal diameters and indexed volumes of LV in diastole and systole are important determinants of postoperative change in LVEF. In patients with preoperative depressed myocardial function, there is an improvement in systolic function, whereas in patients with preserved preoperative myocardial function, the decline in postoperative LVEF was detected.

Introduction

Patients with multivessel coronary artery disease (CAD), especially those with stenosis of the left main (LM) coronary artery and suitable coronary anatomy benefit from coronary artery bypass grafting (CABG) [1], [2], [3]. The goal of CABG is not only to allay symptoms and improve survival [4] but also to optimise cardiovascular function and prevent progressive remodelling. Coronary artery disease (CAD) lead’s to left ventricular (LV) dysfunction as a result of myocardial scarring, stunning, or hibernation [5]. The impact of CABG on regional and global LV systolic function has been studied but with conflicting results, most probably because of patient selection. Most of the studies that evaluated the effect of CABG in patients with severe LV dysfunction showed significant improvement in LV ejection fraction (LVEF) and LV systolic parameters after revascularisation [3], [6], [7].

Moreover, those patients with ischemic symptoms and the most severe LV dysfunction appear to benefit most from surgical revascularisation. On the other hand, only a few retrospective studies evaluate the changes in LV systolic function after CABG in patients with preserved baseline LVEF. In these patients despite the apparent improvement in
cardiac function conventional echocardiography did not change significantly even showed a decline in baseline LVEF [8], [9]. Despite advances in cardiac imaging, we believe that 2-dimensional (2D) echocardiography is still most suitable for detection of myocardial function recovery after CABG to highlight the controversies. This prospective study was designed to evaluate the changes in LV systolic parameters after CABG in patients with both normal and abnormal pre-operative systolic function.

Methods

Study patients

During the period from October 2017 to October 2018, forty-seven consecutive patients undergoing CABG were enrolled in this prospective study. All procedures were done on-pump with cardiopulmonary bypass (CPB). In every case, the left internal thoracic artery (LITA) was used to bypass the left anterior descending artery (LAD). None of the patients had associated surgical procedures such as valve replacement or surgery of the ascending aorta. This study was approved by the Medical Ethics Committee of Medical School, University Ss. “Cyril and Methodius”, Skopje, and all patients provided informed consent.

2-D Echocardiography parameters

Transsthoracic echocardiography was performed within 1 week before CABG as well as 4 to 6 months after surgery. All measurements were made by a single experienced investigator. Standard assessments of LV dimensions, wall thickness, LV mass, LV volumes as well as LV systolic function were performed in standard views using 2D echocardiography and Tissue Doppler imaging (TDI) on commercially available equipment (Vivid 7; GE, USA) according to the professional association recommendations [10].

Statistical analysis

Categorical parameters were summarised as percentages and continuous parameters as mean ± SD. Comparisons of preoperative vs postoperative data were performed using a Wilcoxon Signed Rank test for related samples. Continuous variables were compared using the nonparametric Mann-Whitney test for independent samples and categorical parameters were compared using Pearson’s chi-square test. Assessment of correlations was done using Pearson’s correlation analysis. Stepwise regression analysis was performed to define the independent significant predictive variable of postoperative LV ejection fraction. All data analysis was performed using SPSS version 25.0 (IBM SPSS, Inc., Chicago, Illinois), and p-value ≤ 0.05 was considered significant.

Results

Patient characteristics

The patients were divided into two subgroups: those with normal preoperative LVEF (LVEF > 50% n = 27) and those with abnormal LVEF (LVEF ≤ 50% n = 20). The baseline demographic and clinical characteristics of the patients as a whole and divided in subgroups, including coronary anatomy, and the postoperative course are shown in Table 1 and were similar in both subgroups.

Forty-three percent of patients had decreased LVEF (≤ 50%) at baseline. These patients had significantly lower body mass index, higher Euro SCORE 2 and more likely to have chronic kidney disease. There was no statistically significant difference in age, gender, prior myocardial infarction, SINTAX score and other comorbidities between the groups. Distribution of 3-vessel CAD and significant LM stenosis was also similar between the two groups. The number of bypass vessels was not significantly different between the subgroup of patients with normal, and abnormal LVEF. The majority of patients received three bypass grafts (median 3, range 2–5), and in all patient, a left internal thoracic artery to the left anterior descending coronary artery bypass graft was used (Table 1).

Table 1: Baseline characteristics in the study population as a whole and comparison of demographic, clinical and operative characteristics of 47 patients divided according to the preoperative LVEF

| Parameter | All patients | LVEF > 50% | LVEF ≤ 50% | p |

CABG = coronary artery bypass graft surgery; MI = body mass index; AF = atrial fibrillation; COPD = chronic obstructive pulmonary disease; PCI = percutaneous coronary intervention; COPD = Chronic obstructive pulmonary disease; PVD = peripheral vascular disease; CKD = chronic kidney disease; SINTAX = SYNTAX score; PAD = peripheral arterial disease; TPB = Transplant patient background; LAD = Left Anterior Descending.
Left ventricular myocardial function before and after CABG

Echocardiographic systolic parameters in the study group as a whole and in the subgroups of patients with normal and decreased LVEF before and after CABG are shown in Table 2.

In the study group as a whole there was statistically significant reduction in LVEDVI (p = 0.001), LVESVI (p = 0.003), IVSd (p = 0.037) and WMSI (p = 0.016). There was a significant improvement in MAPSE (p = 0.001). Mean LVEF showed neither improvement nor significant reduction in the whole group of patients (from 54.21 ± 15.36 to 53.66 ± 11.56%, p = 0.677). There were no postoperative changes in other LV measurements including LVIDd, LVIDs, posterior and septal wall thickness, and LVmass index (Table 2).

When we divided our cohort according to the LVEF, significant improvement in LVEF was detected in the subgroup of patients with pre-operative LV dysfunction (from 40.05 ± 8.65 to 45.85 ± 9.04%, p = 0.008), resulting in a mean change in LVEF of 5.80%. On the other hand, there was a statistically significant decline in LVEF in the subgroup of patients with normal pre-operative LVEF (from 64.70 ± 9.72 to 59.44 ± 9.75%, p = 0.008), resulting in a meaningful change in LVEF of −5.26%.

As for the other parameters of systolic function, statistically significant decrease in LVEDVI (p = 0.001), LVESVI (p = 0.0001), WMSI (p = 0.013) and LVmass index in male patients (p = 0.011) was shown only in patients with decreased LVEF after CABG (Table 2).

### Table 2: Comparison of echocardiographic parameters of LV systolic function before and after CABG in patients divided according to the preoperative LEFT

| Parameters | All patients | p | p | p |
| --- | --- | --- | --- | --- |
| LVEF (%) | Before CABG | After CABG | Before CABG | After CABG |
| LVEDVI (ml/m²) | 54.21 ± 15.36 | 53.66 ± 11.36 | 0.677 | 0.008 | 45.85 ± 9.04 |
| LVESVI (ml/m²) | 54.21 ± 15.36 | 53.66 ± 11.36 | 0.677 | 0.008 | 45.85 ± 9.04 |
| IVSd (mm) | 0.016 | 0.001 | 0.001 | 0.001 | 0.001 |
| MAPSE peak (cm/s) | 0.016 | 0.001 | 0.001 | 0.001 | 0.001 |

The only parameter that significantly improved in both groups after CABG was MAPSE (p = 0.035, and p = 0.008 in patients with preserved and reduced LVEF respectively). Except for MAPSE, none of the systolic echocardiographic parameters improved in the subgroup of patients with preserved LVEF (Table 2).

### Parameters related to LVEF change post CABG surgery

In our study, out of 47 patients, 4 patients (8.5%) had unchanged LVEF (+ / -5%) after successful CABG operation, 25 patients (53.2%) had increased LVEF (> 5%) and 18 patients (38.3%) had decreased in the postoperative LVEF (> 5%). Comparison of the three groups (Table 3) showed an only significant difference between patients with improved and decreased postoperative LVEF. Thus, patients with improved postoperative LVEF had significantly lower baseline LVEF (p = 0.0001), higher LVESVI (0.009) and higher WMSI (p = 0.006) vs patients with worsened postoperative LEFT.

### Table 3: Baseline echocardiographic parameters of all patients about perioperative change in left ventricular ejection fraction

| Parameter | Unchanged EF | Improved EF | Worsened EF | p |
| --- | --- | --- | --- | --- |
| LVEDVI (ml/m²) | 48.0 ± 3.9 | 53.7 ± 9.3 | 49.8 ± 8.3 | 0.243 |
| LVESVI (ml/m²) | 29.0 ± 4.2 | 37.1 ± 11.6 | 30.7 ± 8.6 | 0.089 |
| IVSd (mm) | 13.2 ± 2.9 | 12.9 ± 2.4 | 13.1 ± 1.8 | 0.945 |
| PWd (mm) | 10.2 ± 1.5 | 10.8 ± 2.3 | 11.9 ± 1.5 | 0.173 |
| LVEDVI (ml/m²) | 64.1 ± 34.1 | 74.0 ± 33.6 | 51.4 ± 24.7 | 0.069 |
| LVESVI (ml/m²) | 25.7 ± 11.3 | 44.9 ± 30.9 | 20.3 ± 15.5 | 0.0001 |
| LVEF (%) | 56.7 ± 5.1 | 46.6 ± 14.9 | 64.1 ± 11.2 | 0.930 |
| SVI (ml/m²) | 36.5 ± 6.0 | 37.9 ± 10.2 | 38.6 ± 10.7 | 0.386 |
| CI (L/m²/min) | 2.7 ± 0.8 | 2.5 ± 0.7 | 2.6 ± 0.7 | 0.886 |
| MAPSE/average (mm) | 14.1 ± 2.6 | 12.4 ± 1.9 | 13.2 ± 2.5 | 0.277 |
| s'TDI (cm/s) | 5.4 ± 0.9 | 5.9 ± 1.5 | 6.2 ± 1.4 | 0.544 |
| WMSI | 1.3 ± 0.2 | 1.4 ± 0.4 | 1.3 ± 0.3 | 0.006 |

### Postoperative improvement of LVEF

LVEF was correlated with stable angina, lack of perioperative myocardial infarction and angina, higher baseline LV internal diameters and indexed volumes in diastole and systole and lower baseline LVEF (Table 4).

### Table 4: Correlation between the change of LVEF and perioperative parameters

| Parameters | r | p |
| --- | --- | --- |
| Angina (%) | 0.325 | 0.007 |
| Previous MI (%) | 0.388 | 0.049 |
| Smoking (%) | 0.319 | 0.029 |
| LVWI (mm) | -0.294 | 0.045 |
| LVESVI (ml/m²) | -0.404 | 0.005 |
| LVEDVI (ml/m²) | 0.467 | 0.001 |
| WMSI | -0.557 | 0.0001 |
| WMSI | 0.485 | 0.001 |
To determine the independent predictors of improvement of LVEF after CABG, we performed multiple stepwise linear regression analysis with covariates that showed a significant relation to it. The results demonstrated that the value of baseline LVEF appeared as an independent predictor of improved LVEF after CABG (Table 5, Figure 1).

Table 5: Stepwise regression analysis of LVEF after CABG as the dependent variable and clinical and echocardiographic parameters as independent variables in cases for which LVEF improved

| Model | Unstandardized Coefficients | Standardized Coefficients | t | Sig. | 95.0% Confidence Interval for B | Lower Bound | Upper Bound |
|-------|-----------------------------|----------------------------|---|------|--------------------------------|-------------|-------------|
| 0     | Intercept                   | -14.624                    | 4.234 | 3.446 | .002                          | 5.198      | 23.476      |
| 1     | LVEF before CABG            | -8.36                      | .080  | 0.034 | 5.545                          | .000        | .655        |
| 2     | Preoperative systolic       | .00                        | 0.029 | 0.976 | 1.017                          | 0.998       | 1.017       |

a. Dependent variable: LVEF post-CABG

Thus, for every 1% absolute decrease in preoperative LVEF, there is postoperative improvement of LVEF of 0.836% (95% CI 0.655-1.017; p = 0.0001).

Figure 1: Graphical presentation of regression standardised predicted value for LVEF after CABG as the dependent variable in cases for which LVEF improved

Discussion

CABG surgery can improve the myocardial blood supply in the hibernating regions of the heart. This results in increased contractility and better performance of the myocardium [11], [12]. The 2D biplane echocardiography is a widely used method to obtain pre and postoperative systolic parameters of the right and left ventricle in patients undergoing CABG surgery.

In this study, the parameters of LV ejection fraction, LV internal dimensions and LV indexed volumes in systole and diastole, cardiac index, mitral annular plane systolic excursion, wall motion score index and LV mass index obtained with conventional 2D echocardiography were used to assess the global systolic function in patients with CAD undergoing CABG.

We showed deterioration in LVEF after CABG in patients with normal baseline LVEF. Except for MAPSE, other systolic parameters did not change significantly even after successful CABG treatment in patients with preserved baseline LVEF. On the other hand, an improvement in LV systolic function was observed in patients with decreased pre-operative LVEF. There were significant improvement in LVEF, LV systolic and diastolic indexed volumes, WMSI and LV mass index in this subgroup of patients.

Prior studies have similarly found an improvement in LVEF and other systolic parameters in patients with pre-operative LV systolic dysfunction. In the largest prospective, randomised, controlled trial, the STICH trial, Michler et al., [13] in a post hoc subgroup analysis showed a significant improvement in LV size and function in the subgroup of patients with higher baseline LV end-systolic dimensions. Our study also showed improvement in LVEF in the subgroup of patients with preoperative LV systolic dysfunction and higher baseline internal diameters as well as indexed volumes of LV in diastole and systole.

While many studies evaluate changes of perioperative systolic parameters in patients with reduced LVEF, only a few studies examine changes in LV systolic function in patients with preserved baseline LVEF. In a small prospective study, Diller et al. demonstrated improvement in LV diastolic function and did not find a significant reduction in LVEF immediately after CABG [14]. In the largest study to assess pre and post-operative echocardiograms in a population including both normal and reduced pre-operative LV function, Koene et al., [8] showed a decrease in LVEF with CABG in patients with normal baseline LV systolic function. In this study, the magnitude of decrease in LVEF was 3% mean and ranged from -33% to 15%. Our study is in agreement with these findings demonstrating a decrease in LVEF in patients with preserved baseline LVEF resulting in a mean decrease in LVEF of 5.26%. This postoperative decrease in LVEF might result from myocardial stunning [15], reperfusion injury [16] and early postoperative graft failure [17].

In our study, a total of 18 patients (38.3%) had decreased in the postoperative LVEF (> 5%). This suggests that CABG itself contributes to postoperative myocardial dysfunction. Although these patients were angina free 4-6 mounts after CABG, the relative decline in LVEF suggests that myocardial recovery might take longer time. We strongly believe that these results are worthy of further investigation to understand the effect of CABG on myocardial function. Another issue that should be investigated is whether the lack of improvement of LVEF post-CABG portends a worse outcome.

The major limitations in our study are that we used only conventional 2-D echocardiography imaging to assess pre and postoperative systolic LV function. Other technologies such as magnetic resonance imaging...
imaging, positron emission tomography and speckle tracking imaging might have yielded other results, but 2-D echocardiography is a widely used method for quantifying perioperative LV function. This study has the advantage of being prospective and all consecutive patients that met inclusion criteria were enrolled in the study but we believe that their number is too small and is thus hypothesis-generating rather than definitive. Another disadvantage is that paired echocardiograms were done a maximum of 6 months after surgery, time that might be too short for complete myocardial recovery after surgery. In our study, all patients were done on the pump with crystalloid cardioplegia and this might affect postoperative LV function in a certain percentage of patients.

In conclusion, our study showed that LVEF, internal baseline diameters and indexed volumes of LV in diastole and systole are important determinants of postoperative change in LVEF. In patients with the preoperative depressed myocardial function, we should expect improvement in systolic function, whereas in patients with preserved myocardial function, decline in postoperative LVEF should be anticipated, despite successful CABG. The present study suggests further investigations in order to understand the effect of CABG on myocardial function.
