Abstract

Background

Enterovirus 71 (EV71) vaccine, which was put into market in China in 2016, has been viewed as a promising prevention measure against severe and fatal hand, foot and mouth disease (HFMD). This study aimed to investigate the knowledge of HFMD and acceptability of EV71 vaccine among parents of under-five in Chongqing, China.

Methodology /Principal findings

A cross-sectional survey was conducted in 2017. A validated questionnaire consisting of three sections including demographic information, knowledge of HFMD, acceptability and reasons for declining vaccination was developed based on literature review. Factors associated with unwillingness to receive EV71 vaccine were explored using multivariate logistic regression. A total of 992 parents finished the questionnaire with a response rate of 91.9%. Awareness of HFMD and EV71 vaccine were reported by 823 (83.0%) parents and 386 (38.9%) parents respectively. Knowledge about HFMD was with a mean score of 5.0 (standard deviation = 3.5) out of a total score of 12. Only 369 (37.2%) participants were classified as with good knowledge level about HFMD. 279 (28.1%) participants had their children received EV71 vaccine and 271 (27.3%) expressed willingness to vaccinate their children after a short-time education about EV71 vaccine. Acceptability of EV71 vaccine increased along with parents’ education level (p = 0.008) and HFMD knowledge level (p<0.001). Parents of scattered children had higher acceptability than those of preschool children (p = 0.002). 442 (44.6%) of participants were unwilling to have their children vaccinated with EV71 vaccine. The most common reasons for declining EV71 vaccine were doubts about its safety (56.6%) and efficacy (48.3%), and the necessity of vaccination (38.3%). Physicians and vaccination certificate were the parents’ most trusted sources of vaccine information.
Conclusions
Parents’ knowledge about HFMD was not sufficient, and nearly half of the parents expressed unwillingness to vaccinate their children with EV71 vaccine. Our findings stress that more efforts by health authorities in Chongqing are needed to increase the acceptability of EV71 vaccine, especially among parents of preschool children with lower education level.

Introduction
Hand, foot and mouth disease (HFMD) is an infectious disease caused by a group of enteroviruses [1]. Most HFMD cases are mild and self-limited; however, some cases rapidly develop serious complications such as meningitis and encephalitis, which can be fatal [2]. Infection with enterovirus 71 (EV71) is of particular concern as it is responsible for most of the severe and fatal HFMD cases, particularly in the Asia-Pacific region [3]. In China, EV71 accounted for more than 90% of laboratory-confirmed fatal HFMD cases between 2008 and 2013 [4]. Moreover, EV71 is also associated with many severe diseases in young children (aged < 5 years), including aseptic meningitis and encephalitis [5, 6]. To date, there is no effective antiviral medications to protect against EV71-associated diseases [7, 8]. The preventive measures suggested by World Health Organization are good hygiene, frequent hand washing and social distancing, which seem to have a limited effect on EV71-associated HFMD control and prevention [7, 9]. EV71 vaccine has been viewed as a promising prevention measure against severe and fatal HFMD [10]. Three inactivated EV71 vaccines were licensed by the Chinese Food and Drug Administration (FDA) in December 2015 and recommended for children [11–13]. However, limited data have been collected on the acceptability of EV71 vaccine among parents since the approval of the vaccine by Chinese government.

Chongqing, the largest municipality under direct control of the national government in China, is located in the southwestern China, which is one of the most seriously affected areas by HFMD in China [14]. EV71 vaccine has been put into market in Chongqing since 2016. The aim of this study was to assess parents’ knowledge, attitudes and practices regarding HFMD and EV71 vaccination in Chongqing and to identify potential factors influencing EV71-vaccine uptake.

Materials and methods
From July 17 to August 14 in 2017, we conducted a cross-sectional survey in 18 primary health centers in Chongqing. A total of 1,080 parents were selected via a three-stage sampling method. At stage 1, nine districts/counties were randomly selected from 39 districts/counties of Chongqing. At stage 2, two primary health centers (PHCs) were randomly selected from each of the sampled district/county, resulting in 18 selected PHCs. At the final stage, 60 parents of children under 5 who attended the PHCs to have their children vaccinated with EV71 vaccine or other vaccines, were selected and invited to participate in a face-to-face interview in each PHC during the proposed study period. The first parent was selected randomly and then the subsequent parents were selected contiguously till the completion of the required sample size. We excluded those parents whose children had a history of suffering HFMD.

The questionnaire was developed by the research team based on literature review [15–16] and tested in a pilot study. The questionnaire included three parts: (1) demographic characteristics, such as age, gender, education level, number of children, and monthly family income;
(2) awareness and knowledge of HFMD and EV71 vaccine; (3) acceptability and reasons for not accepting EV71 vaccination.

Awareness of HFMD and EV71 were assessed with the questions “Before today, had you heard of HFMD?” and “Before today, had you heard of EV71 vaccine?”. Parents who answered “yes” to the question were considered to be aware of HFMD and EV71 vaccine. Those who were not aware of EV71 vaccine were given basic information on EV71 vaccine by the interviewer prior to continuing the interview.

Knowledge of HFMD was collectively assessed with 12 single choice question with items of “yes”, “no”, and “don’t know”. Each correct answer was given one point, and each incorrect answer or “don’t know” was given zero point. The total knowledge score ranged from 0 to 12. Finally, all respondents were divided into two groups based on their total knowledge score: good (≥ 8 correct out of 12) and poor (< 8 correct out of 12). The questions “have you already vaccinated your children with EV71 vaccine?” and “are you willing to vaccinate your children with EV71 vaccine?” were used to assess the acceptability of EV71 vaccine. Parents who answered yes to either of the two questions were considered to have good willingness to take EV71 vaccine. For parents who answered “no” to both questions were further asked to give their reasons for not accepting vaccine with a multiple choice question with 5 specified reasons and one open choice (“Others, please specify”).

We conducted a pilot survey with a small sample of participants (n = 50) to test the acceptability and feasibility of the questionnaire. Based on the results of the pilot survey, some minor wording changes were made in the revised version, which was then used in this study.

### Statistical analysis

Descriptive statistics were obtained for all survey items. The Chi-square tests were used for comparisons between categorical variables. Univariate analysis was conducted to compare factors influencing acceptability of EV71 vaccinations, for those factors with statistical significance (p < 0.05) were included in multivariate logistic regression analysis. SPSS Statistics software (Release 25.0, SPSS Inc, and IBM Company, Chicago, IL, USA) was used for all of the statistical analyses.

### Ethical approval

The study protocol and the verbal informed consent process were approved by the Ethic Committee of Chongqing Center for Disease Control and Prevention. Verbal consent was obtained from all participants-parents. All data analyzed anonymously.

### Results

#### Demographics

A total of 1,080 parents were invited to participate in the survey. Of them, 992 (91.9%) parents completed the questionnaires and were included in the analysis, while 88 parents refused. Demographic characteristics of participants were summarized in Table 1.

Of the 992 participants, 67.8% (673/992) were mothers and 32.2% (319/992) were fathers with the mean age of 28.5 (range: 20–44 years). Most commonly reported education level was high school or above (58.1%, 576/992). Of the 992 children who were vaccinated on the survey days, 50.3% (499/992) were boys and 49.7% (493/992) were girls with mean age of 1.6 (range: 1 month–5 years old). Majority of them (81.2%, 806/992) were scattered children and 18.8% (186/992) were preschool children.
Awareness and knowledge of HFMD

Most (83.0%, 823/992) of the participants had heard of HFMD before the investigation. However, their knowledge regarding the characteristic symptoms, infectiousness, prevention measures and transmission routes of HFMD varied significantly (Table 2). Indeed, 75.1% of them knew HFMD is infectious and characterized by non-itchy red rash with blisters on the hands and feet and painful mouth ulcers (60.4%), whereas the awareness of other aspects was poor. Particularly, less than one third of participants knew the transmission routes of HFMD.

The mean score of HFMD knowledge was 5.0 (SD = 3.5) out of 12. A total of 369 (37.2%) participants were classified as with good knowledge related to HFMD, 454 (62.8%) were classified as having poor knowledge (Table 3).

Table 1. Demographic characteristics of participants in the study of knowledge of HFMD and acceptability of EV71 vaccine among parents of under-five in Chongqing, China.

| Characteristics               | Number | Percentage (%) |
|-------------------------------|--------|----------------|
| Total number                  | 992    |                |

| High                          | 444    | 44.8           |
| Refuse to answer              | 33     | 3.3            |
| Children’s gender             |        |                |
| Boy                           | 499    | 50.3           |
| Girl                          | 493    | 49.7           |
| Children’s category           |        |                |
| Scattered children            | 806    | 81.2           |
| Preschool children            | 186    | 18.8           |
| Number of children in the family |      |                |
| One                           | 714    | 72.0           |
| ≥ Two                         | 278    | 28.0           |
| Parents’ age                  |        |                |
| 20–29 years old               | 522    | 52.6           |
| 30–39 years old               | 411    | 44.5           |
| 40 years old and above        | 29     | 2.9            |
| Children’s age                |        |                |
| Less than 1 years old         | 408    | 41.1           |
| 1– years old                  | 235    | 23.7           |
| 2– years old                  | 163    | 16.4           |
| 3– years old                  | 100    | 10.1           |
| 4–5 years old                 | 86     | 8.7            |

*Note: Scattered children are defined as children whose cares were given by their family members and generally younger than 3 years old. Preschool children are classified as those children who are enrolled in the kindergarten or the nursery, who are usually older than 3 and younger than 5 in this study.

Awareness and knowledge of HFMD

Most (83.0%, 823/992) of the participants had heard of HFMD before the investigation. However, their knowledge regarding the characteristic symptoms, infectiousness, prevention measures and transmission routes of HFMD varied significantly (Table 2). Indeed, 75.1% of them knew HFMD is infectious and characterized by non-itchy red rash with blisters on the hands and feet and painful mouth ulcers (60.4%), whereas the awareness of other aspects was poor. Particularly, less than one third of participants knew the transmission routes of HFMD.

The mean score of HFMD knowledge was 5.0 (SD = 3.5) out of 12. A total of 369 (37.2%) participants were classified as with good knowledge related to HFMD, 454 (62.8%) were classified as having poor knowledge (Table 3).
Information about EV71 vaccine

Only 386 (38.9%) participants had heard of the EV71 vaccine before, and most got the information about EV71 vaccine from their physicians (Fig 1).

Regarding their most trusted vaccine information source, the majority of participants preferred physicians (94.4%, 936/992) and vaccination certificate (93.1%, 924/992), followed by friends (57.1%, 566/992) and lectures (50.4%, 500/992), while other information channels were considered as less credible (Fig 2).

Acceptability of EV71 vaccine

A total of 279 participants (28.1%) had already vaccinated their children with EV71 vaccine by the survey time and 271 (27.3%) expressed willingness to vaccinate their children after a short-time education about EV71 vaccine during the investigation. However, 442 (44.6%) participants declined vaccination. There were a few of possible reasons for unwillingness to vaccinate their children with EV71 vaccine: 56.6% (250/442) respondents concerned about the safety of the vaccine, and 48.3% (213/442) concerned about its efficacy. In addition, 38.3% (169/442) doubted its necessity. 24.4% (108/442) of the participants thought that the vaccine too expensive, and 11.3% (50/442) considered HFMD as a mild illness (Fig 3).

The characteristics of participants who accepted EV71 vaccine and those who declined EV71 vaccine were compared by \( \chi^2 \) test and presented in Table 4. In univariate analysis, the following factors were statistically significantly associated with the acceptability: parents’ education level and knowledge of HFMD, monthly family income and children’s category. All covariates were included in the multiple logistic regression model.

From the multiple logistic regression analysis, children’s category, parents’ education level and knowledge of HFMD were significantly and independently associated with the...
Parents of scattered children were 1.79 times more likely to vaccinate their children (OR = 1.79, 95CI: 1.29–2.50) compared to those of pre-school children. Parents with education level of high school or above were 1.54 times more likely to vaccinate their children (OR = 1.54, 95CI: 1.08–2.21) than those with education level of primary school or below. Parents with good knowledge of HFMD were 1.67 times more likely to vaccinate their children (OR = 1.67, 95CI: 1.27–2.20) compared to those with poor knowledge of HFMD.

**Discussion**

EV71 vaccines have been put into market in China since 2016 and have been viewed as a promising prevention measure against severe and fatal HFMD [12, 17]. The objective of this
The study was to provide useful information for further research on HFMD vaccine and immunization strategy of the EV71 vaccine. The result indicated a suboptimal EV71 vaccine acceptability among parents of under-five in Chongqing, China. Only 28.1% of participants had their children vaccinated and 44.6% declined even after being given the official EV71 vaccine recommendation statement during the investigation. This coverage rate is lower than other extra expanded immunization program (EPI) vaccines classified as class 2, which are not free of charge, such as chickenpox vaccine, which was 44.7% in urban areas of Chongqing [18]. Several factors might be proposed to explain the low vaccine acceptability.

Firstly, lack of propaganda about the EV71 vaccine and the fact that the vaccine was available recently. In this study, only 38.9% of participants had heard of EV71 vaccine before the investigation. The result showed 27.3% of participants expressed willing to vaccinate their children after a short-time education about EV71 vaccine during the investigation. This finding suggests health publicity and education on EV71 vaccine should be enhanced. Regarding the different vaccine information sources, physician was the most credible source, followed by vaccination certificate. Therefore, it would be helpful for doctors to recommend EV71 vaccine to parents and provide them with information about the risks of EV71 infection and benefits of vaccination [19]. It is also advisable to conduct studies to explore the factors associated with recommendation of EV71 vaccination by physicians. Moreover, promotion of EV71 vaccine through vaccination certificate might be also a cost-effective immunization implementation strategy.

Secondly, poor knowledge of HFMD among parents also contributed to the poor acceptance of EV71 vaccine. The mean score of HFMD knowledge was only 5.0 out of 12. The multivariable analysis showed that parents’ knowledge on HFMD was significantly positively associated with acceptability, as was reported by other similar studies [20–22]. Furthermore, parents of higher education level and of scatter children were more likely to vaccinate their children, which is consistent with other studies [23, 24]. The findings suggest that enhancing public education on HFMD knowledge might improve their willingness to vaccinate their children, and the information needs to be communicated in simplified language for parents with lower education level. EV71 vaccination among children is one of the most effective means of...

https://doi.org/10.1371/journal.pone.0225569.t004

preventing HFMD transmission in such places as kindergartens and nurseries, where the virus can be rapidly spread. Therefore, it is advisable to enhance health publicity and education on HFMD and EV71 vaccine in these places.

Thirdly, lack of confidence in the safety and efficacy of the EV71 vaccine directly lead to a low acceptance, which is similar to previous studies on other vaccines [25, 26]. The top two reasons against vaccination were “concern about the safety of vaccine” and “concern about the efficacy of vaccine”, accounting for 56.6% and 48.3% of those participants unwilling to vaccinate their children. It reflected the misconception about EV71 vaccine among parents. Nowadays, in China, there is an irrational panic and wide-spread concern about vaccination as result of many misreported adverse events about vaccination [27]. When a new vaccine such as EV71 vaccine is licensed for use, the people become more cautious about it. Therefore,
future health education campaigns and messages should be aimed at easing concerns about safety and effectiveness of EV71 vaccine in parents.

There is no single intervention strategy that works for all aspects of vaccination hesitancy. The tailed strategies to improve vaccine acceptability should be developed based on the different areas and vaccines. According to the results in our study, we can improve the acceptability of EV71 vaccine from the following three aspects. Firstly, HFMD knowledge level and awareness of EV71 vaccine of the target parents must be improved. Appropriate incentives should be given to physicians to increase their involvement [28]. The contents of the health education should include those aspects which parents with poor knowledge, such as the routes of transmission. Secondly, people's concerns about safety and efficacy of EV71 vaccine should be echoed. To help address misconceptions among parents, tailed educational messages should be targeted at parents. Thirdly, strong physician recommendation and promotion through vaccination certificate were key facilitators to optimize uptake of EV71 vaccine in this region.

Our study could be interpreted with some limitations. Firstly, the convenient samples of parents who attended the PHCs to vaccinate their children during the proposed study period may not adequately represent the population in Chongqing. Secondly, the cross-sectional nature of this study limits the extent to which we can evaluate changes in KAP across time. Finally, the EV71 vaccination status of children was self-reported and not verified through records.

Conclusions
In conclusion, parents' knowledge about HFMD was not sufficient, and nearly half of parents expressed unwillingness to vaccinate their children with EV71 vaccine in Chongqing. Misconceptions about EV71 vaccination were prevalent among parents. Our findings stress that more efforts by health authorities in Chongqing are needed to increase the acceptability of EV71 vaccine, especially for parents of preschool children with lower education level.
