Abstract

For a long time, colorectal cancer (CRC) has been ranked among the top cancer-related mortality rates, threatening human health. As a significant post-translational modification, O-GlcNAcylation plays an essential role in complex life activities. Related studies have found that the occurrence, development, and metastasis of CRC are all related to abnormal O-GlcNAcylation and participate in many critical biological processes, such as gene transcription, signal transduction, cell growth, and differentiation. Recently, nucleotide sugar analogs, tumor-specific carbohydrate vaccine, SIRT1 longevity gene, dendritic cells as targets, and NOTCH gene have become effective methods to induce antitumor therapy. Not long ago, checkpoint kinase 1 and checkpoint kinase 2 were used as therapeutic targets for CRC, but there are still many problems to be solved. With an in-depth study of protein chip, mass spectrometry, chromatography, and other technologies, O-GlcNAcylation research will accelerate rapidly, which may provide new ideas for the research and development of antitumor drugs and the discovery of new CRC diagnostic markers.

Key Words: Colorectal cancer; O-GlcNAcylation; Antitumor therapy; CHK1 and CHK2; Chip; Diagnostic markers

INTRODUCTION
Colorectal cancer (CRC) is a common highly malignant digestive tract tumor worldwide, and it is also the third leading cause of cancer-related death in the world[1]. Once distant metastasis occurs, especially liver metastasis, cancer-related mortality increases significantly[2]. So far, more than 400 post-translational modification types and more than 80 000 protein-specific post-translational modification sites have been reported, including glycosylation, phosphorylation, acetylation, methylation, and ubiquitination[3]. O-GlcNAcylation is a critical glycosylation modification. Studies have shown that the change of O-GlcNAcylation is a marker of CRC, and the inactivation of functional molecules involved in O-GlcNAcylation hinders the biosynthesis of normal glycosylation structures, thus promoting the progression and metastasis of CRC[4]. Table 1 shows the summary of studies on O-GlcNAcylation and CRC in the last 5 years. Table 2 summarizes the gene targets associated with O-GlcNAcylation in CRC. This article mainly reviews the occurrence and development of O-GlcNAcylation in CRC and the corresponding therapeutic targets.

O-GLCNACYLATION AND ITS PHYSIOLOGICAL EFFECTS
O-GlcNAcylation refers to a single N-acetylglucosamine (GlcNAc) with O-glycoside bond to a protein serine or threonine hydroxyl oxygen atom to modify the protein in the nucleus and cytoplasm[5]. O-GlcNAcylation precursors include Tn, sialic acid Tn (sTn), core1, core2, core3, core4, and N-acetyllactosamine (Table 3). O-GlcNAcylation is a dynamic protein modification process. The addition and removal of modification sites have been reported, including glycosylation, phosphorylation, acetylation, methylation, and ubiquitination[6]. O-GlcNAcylation is the only donor for the O-GlcNAcylation of protein[7]. When the content of glucose, glucosamine, or free fatty acid increase under hypoxia, heat shock, radiation, and other stress conditions or when the key enzyme in the hexosamine pathway is overexpressed, glucose is transformed into glucose-6-phosphate and then fructose-6-phosphate under the action of hexokinase. Most fructose-6-phosphate enters the glycolysis pathway, and approximately 2%-5% fructose-6-phosphate enters the hexosamine pathway (Figure 1). The end product UDP-GlcNAc is synthesized with the participation of glutamine, which raises the O-GlcNAcylation level of intracellular protein[7].

Physiological effects of O-GlcNAcylation
Recent studies have shown that O-GlcNAcylation is related to tumorigenesis and the development and initiation of malignant biological phenotypes[5]. It can regulate various physiological and pathological processes by affecting the function, location, conformation, and degradation of target proteins[8], and it is involved in many processes, such as cell signal transduction, gene transcription, cell division, metabolism, and cytoskeleton regulation[9]. More importantly, the change of O-GlcNAcylation is related to cell development, mitosis, proliferation and survival, and tumor metastasis[10]. O-GlcNAcylation can enhance the stability and transcriptional

(2) qRT-PCR. (3) Stalic acid colorimetric assay. (4) O-glycan colorimetric assay. (5) Isolation of intestinal glycans. (6) Glycan derivatization. And (7) Analysis by MALDI-LIFT-TOF/TOF MS | The role of glycosylated proteins in the regulation of epithelial cells to limit the penetration of intestinal bacteria into the mucosa during microbial community composition changes and/or the acquisition of new organisms from the environment. It is essential to understand whether intestinal O-GlcNAcylation changes through changes in microbial communities or by signaling directly to...
Table 2 Gene targets associated with O-GlcNAcylation in colorectal cancer

| Category                        | Action site     | Type                | Pathway                                                                 | Influence                                                                 |
|--------------------------------|-----------------|---------------------|------------------------------------------------------------------------|---------------------------------------------------------------------------|
| Tumor suppressor gene           | APC[94]          | CPC; Apc cell       | APC/Wnt/β-catenin signaling pathway                                    | Affect apoptosis and growth                                               |
| GT41                            | OGT[100]         | HT29 cell           | OGT silencing                                                          | Accelerate invasion and metastasis                                        |
| OGA[101]                        | SW480 cell       | (1) OGA silencing. And (2) p53 signaling canonical Pathway       | Be a potential key regulator of the malignant phenotype of CRC          |
| Polypeptide N-GALNT12           | T491M[102]       | Germ line cell      | Genetic mutations                                                       | Lead to CRC susceptibility                                               |
| T491M[102]                      | R373H[102]       | Cell signaling pathway | Be a potential key regulator of the malignant phenotype of CRC          |
| Programmed Cell Death Protein 1 | PD-L1[103]       | CD8+ cell           | β-catenin/STT3 signaling pathway                                       | Accelerate immune evasion and reduce apoptosis                            |
| (PDCD1)                         |                 |                     |                                                                        |                                                                           |
| GalNAc-transferases (GalNAc-Ts) | GalNAc-T[105]    | Primary cell        | -                                                                      | Promote differentiation and invasion                                       |
| GalNAc-T[105]                   | Wild Type (WT) LS174T cell | - Cell signaling pathway | Be a potential key regulator of the malignant phenotype of CRC          |
| Tumor Necrosis Factor Receptor (TNFR) | Death Receptor (DR)-4 and DR-5[106] | GALNT14 genotypes and stage III Cell | Trigger the mechanism of apoptosis.                                   |
| G Protein-Coupled Receptors (GPCRs) | CXCR4[107]    | CXCR4+/−/ ApcMin+/− cell | (1) IncRNA XIST / miR-133a-3p/RhoA signaling pathway. And (2) JAK2-STAT3 inflammatory signaling pathway. And (3) CXCL12/CXCR4 axis | (1) Increase IL-1, IL-6, and TNF levels. (2) Invasion and Metastasis. (3) Recruit immune suppressive cells. And (4) Regulate RhoA expression by sponging miR-133a-3p |
| Transforming Growth Factor (TGF) | TGF-β[108]       | CD44+ cell          | TGF-beta signaling pathway                                             | Enhance stem cell properties                                             |
| TWIST1[109]                     | CD44+ cell       | TGF-beta signaling pathway                                     | Enhance stem cell properties                                             |
| TGFβR2[109]                     | pI33-associated cell | p21-mediated/ TGF-β signaling pathway | Cause reduced p21 activation and reduced apoptosis                   |
| Rho                             | RhoA[110]        | CXCR4-overexpressing HCT116 cell | RhoA/ROCK signaling pathway                                           | (1) Regulate RhoA expression by sponging miR-133a-3p. And (2) Promote the formation of actin stress fiber and actin contractile force |
| Transmembrane mucins            | MUC1[109]        | MUC1 (+) cell       | PDI/PD-L1 signaling pathway                                            | Recruit inflammatory cytokines and evade immune surveillance.            |
| MUC2[110]                       | Muc2/ Apc and Apc Min+/− cell | (1) Wnt signaling pathway. And (2) Genetic Inactivation | Contribute to the risk of developing CRC by changes in their levels |
| MUC4[111]                       | early stage (stage I and II) cell | β-catenin signaling pathway                                           | Predict poor survival among patients                                      |
| MUC3[112]                       | colitis-associated cell | β-catenin signaling pathway                                           | Increase nuclear translocation of β-catenin and drive the development, progression, invasion and immunosuppression |
activity of some circadian clock proteins and affect the phosphorylation and cellular localization of other clock proteins. Inhibition of the O-GlcNAcylation of circadian clock proteins leads to the decline of cell rhythms and the downregulation of multiple circadian genes. O-GlcNAcylation can regulate the cycle length and amplitude of circadian rhythm[20].

O-GlcNAcylation and CRC

O-GlcNAcylation and CRC cell cycle and proliferation

O-GlcNAcylation is closely related to cell growth and development[21]. Abnormal changes of O-GlcNAcylation may lead to tumor transformation of CRC cells[22]. In addition to genetic, metabolic, and proteomic characteristics, O-GlcNAcylation is a major factor in colon differentiation and CRC occurrence[23]. Studies have shown that the malignant transformation changes the O-GlcNAcylation mechanism of cells and affects the function of carcinogenic receptors involved in the control of cell proliferation and differentiation[24]. In CRC cells, the activation of Thr58 of proto-oncogene c-Myc may increase the level of O-GlcNAcylation, and the increase in O-GlcNAcylation level can inhibit the phosphorylation modification at the same site, thus blocking the degradation of c-Myc, maintaining the high-level expression of c-Myc, and promoting the proliferation and differentiation of CRC cells[25]. The O-GlcNAcylation of tumor suppressor gene p53 at the Ser149 site also promotes the growth of tumor cells[26]. Since glucose is the precursor substrate in the reaction leading to UDP-GlcNAc, the level of O-GlcNAcylation is also increased along with the increase in glucose level in CRC cells, which is accompanied by a synchronous increase of glutamine fructose aminotransferase and OGT[27]. In vitro studies showed that OGT could be repositioned to the deoxyribonucleic acid (DNA) damage site and catalyze the O-GlcNAcylation reaction of histone H2AX, the mediator of DNA damage checkpoint 1 and histone H2A. O-GlcNAcylation enhances double-strand break repair in vivo and in vitro and promotes the proliferation of cancer cells[28]. OGT knockout is lethal in embryonic stem cells, embryonic fibroblasts, or tissues[29]. Therefore, in the process of tumorigenesis, O-GlcNAcylation is likely to promote cell proliferation by regulating the cell cycle, leading to carcinogenesis[30]. The fluctuation of O-GlcNAcylation has been correlated with the cell cycle—the lowest in the M phase, and the highest in G1/S and G2/M phases[31]. Peng et al.[32] reported that OGT-mediated O-GlcNAcylation plays an essential role in the activation of the Hippo Yap pathway and found a new mechanism of extracellular nutrition signal regulating the Hippo pathway and tumor growth[33].

The transcription factor Yin Yang 1 (YY1) plays an important role in different biological processes such as embryogenesis, cell proliferation, and cancer progression[34]. It has been proved to be a target for various post-translational modifications, including ubiquitination, acetylation, O-GlcNAcylation, S-nitrosation, etc. Ample data show that YY1 expression is not regulated in many cancers, and most of them are related to the clinical behavior of different types of tumors[35]. Zhu et al.[36] have shown that YY1 stimulates the occurrence of CRC and increases the protein stability of YY1 through O-GlcNAcylation, which helps it play a proto oncogenic role in CRC[37].

O-GlcNAcylation and stress of CRC cells

The health of the body is regulated by several molecules and biochemical networks responsible for maintaining homeostasis in cells and tissues. However, an imbalance of homeostasis often occurs in response to various endogenous and environmental pressures, resulting in the accumulation of damage and increased sensitivity to diseases[38]. O-GlcNAcylation can dynamically regulate intracellular metabolism and signaling pathways, thus enhancing the resistance of CRC cells to various stimuli from the environment and itself. O-GlcNAcylation signal is considered essential stress and metabolic sensor. Increasing OGT expression or inhibiting OGA expression can enhance the stress tolerance of CRC cells; knockout of OGT or blocking of the hexosamine biosynthetic pathway will lead to apoptosis[39]. Excessive nutritional intake and hyperglycemia were thought to be the sources of the hexosamine biosynthetic
Table 3 Several common O-GlcNAcylation precursors

| Basic structural unit | Chemical formula |
|-----------------------|------------------|
| Tn antigen            | GalNacα-O-Ser/Thr |
| STn antigen           | Siaα2-6GalNacα-O-Ser/Thr |
| Core 1 (T antigen)    | Galβ1-3GalNacα-O-Ser/Thr |
| Core 2                | GlcNacβ1-6(Galβ1-3)GalNacα-O-Ser/Thr |
| Core 3                | GlcNacβ1-3GalNacα-O-Ser/Thr |
| Core 4                | GlcNacβ1-6(GlcNacβ1-3)GalNacα-O-Ser/Thr |
| LacNAc                | Galβ1-3GlcNAc(3Type I) or Galβ1-4GlcNAc(2Type 2) |
| H-antigen             | Fucα1-2Gal |

GalNAc: N-acetylgalactosamine; LacNAc: N-acetyllactosamine; STn: Sialic acid Tn.

pathway and contribute to the abnormally elevated O-GlcNAcylation level in CRC cells[30]. Therefore, the generally elevated O-GlcNAcylation level in CRC was considered to be a key factor in the occurrence and development of CRC[31]. Han et al[32] found that under pressure stimulation of genotoxicity, oxidation, and metabolism, the O-GlcNAcylation of SIRT1 is significantly increased[32]. The circulatory imbalance of O-GlcNAcylation on tumor-related targets, including DNA damage repair-related proteins and stress-related pathways, may contribute to tumorigenesis.

As a molecular chaperone of the endoplasmic reticulum, core 1 β3-galactosyltransferase (COSMC) may be induced by endoplasmic reticulum stress in cancer cells. It is associated with many aspects of the endoplasmic reticulum. Under endoplasmic reticulum stress, many chaperones are upregulated in cancer, including...
heat shock proteins and lectin-like chaperones\textsuperscript{39}. Related studies have shown that Tn and sTn antigens are expressed in many types of cancer, including CRC, lung cancer, bladder cancer, cervical cancer, ovarian cancer, thyroid cancer, and breast cancer\textsuperscript{40}. The findings in CRC cell lines and specimens suggest a more complex mechanism of Tn expression. The increase in the Tn antigen may also regulate the production of T-synthase/COSMC through a feedback loop\textsuperscript{39}. In addition, the expression of the Tn antigen may be caused by the maladjustment of other enzymes, such as acetylgalactosaminyl-O-glycosylglycoprotein beta-1,3-N-acetylgalactosaminyltransferase. This enzyme transforms Tn antigens parallel to the T-synthase/COSMC complex in the gastrointestinal tract\textsuperscript{42}. It inhibits metastatic potential and is downregulated in CRC cancer\textsuperscript{42}. Mice lacking core-3-derived O-glycans were more susceptible to CRC\textsuperscript{42}.

O-GlcNAcylation regulates glycolysis of cancer cells through hypoxia-inducible factor-1 (HIF-1α) and its transcription target GLUT1. The reduction of O-GlcNAcylation increased a-ketoglutarate, hydroxylated HIF-1, and changed the levels of the von Hippel Lindau protein, resulting in the degradation of HIF-1α. In CRC cells, hypoxia can also upregulate UGT-1 transcription\textsuperscript{43}. UGT-1 transports UDP-Gal and UDP-GalNAc, suggesting that hypoxia regulates O-GlcNAcylation by affecting the nucleotide sugar pool\textsuperscript{43}. Reducing the expression of O-GlcNAcylation in cancer cells can induce the activation of endoplasmic reticulum stress and apoptosis of cancer cells through CCAAT/ enhancer binding protein homologous protein. Cancer cells may use the O-GlcNAcylation pathway of a nutritional sensor to regulate critical metabolic factors, such as HIF-1α and c-Myc, which is necessary for maintaining glycolysis flux, rapid cell growth, and survival\textsuperscript{43}.

**O-GlcNAcylation and recurrence, invasion, and metastasis of CRC cells**

Uncontrolled cell division, extensive cell survival, and promotion of angiogenesis are characteristics of tumorigenesis\textsuperscript{44}. O-GlcNAcylation affects the proliferation, recurrence, metastasis, and malignant transformation of tumor cells\textsuperscript{45}. The expression of the sTn antigen in m/z 2691 of recurrent tumors was significantly higher than in non-recurrent tumors, i.e. overexpression of Tn and sTn antigens was a characteristic feature of advanced and poorly differentiated CRC\textsuperscript{46}. The overexpression of the sTn antigen is associated with the upregulation of ST6GALNAC1 and the decrease of core 1 synthase gene (C1GALT1) in the mucinous CRC cell line LS174T\textsuperscript{47}. Analysis of mucin glycosylation of recurrent tumors showed that the proportion of core-3 O-glycan was higher than in non-recurrent tumors, while the expression of core-1 O-glycan was weaker. ST6GalNAc II controlled the sialic acidolysis of the T antigen. Overexpression of T antigen messenger ribonucleic acid was associated with a low survival rate of CRC patients with lymph node metastasis\textsuperscript{48}. The changes of O-GlcNAcylation in CRC include a decrease of the number and length of apolipoprotein carbohydrate side chains, loss of normal expression antigen, the reappearance of new antigen, and expression of blood group incompatible antigen\textsuperscript{49}. In RKO and SW620 cells, integrin α5 (ITGA5) protein can be degraded by O-GlcNAcylation, and the increase of O-GlcNAcylation significantly slows down the degradation of ITGA5 protein, while the decrease of O-GlcNAcylation accelerates the degradation of ITGA5 protein, which indicates that the O-GlcNAcylation of ITGA5 endows ITGA5 enhancer with the ability to promote the progression of CRC\textsuperscript{50}.

Cancer cell invasion and metastasis require many steps, including epithelial-mesenchymal transition (EMT)\textsuperscript{51}. This phenomenon is usually caused by the activation of β-catenin/ Snail 1, which is in turn caused by abnormal signals, and then affects the downstream protein transcription. Studies have shown that O-GlcNAcylation reduces the expression of E-cadherin on the cell surface by directly modifying β-catenin, thus promoting tumor metastasis\textsuperscript{51}. In two CRC cell lines (HCT116 and SW480) with stable and high expression of COSMC, ZO-1, another epithelial marker, was proved to be significantly reduced and the expression of several mesenchymal cell markers was increased, which fully reflects the characteristics of EMT\textsuperscript{51}. The elevated level of O-GlcNAcylation in metastatic CRC tissues and cell lines may contribute to EMT by enhancing the stability of and function of zeste homolog 2 protein, demonstrating strong lymph node metastasis potential and a lower overall survival rate. The O-GlcNAcylation and H3K27me3 modification in the miR-101 promoter region inhibited the transcription of miR-101, leading to the upregulation of OGT and enhancer of zeste homolog 2 in metastatic CRC, thus forming a vicious circle\textsuperscript{52}. The initiation of mucin O-GlcNAcylation in the endoplasmic reticulum promotes the invasiveness of cancer cells. Fibroblast growth factor receptor 2 (FGFR2) and its subtypes are highly expressed in CRC. C1GALT1 can regulate the O-GlcNAcylation of FGFR2 and its downstream signal molecule ERK, and
promote tumor growth, metastasis, and angiogenesis\textsuperscript{53}. Recent studies have shown that CCL17 and interleukin-13 (IL-13) produced by the Co-culture of M2 macrophages and colon cells in CRC could activate the AKT and STAT6 oncogenic pathways, among others. CCL17 and IL-13 also induced abnormal overexpression of ST6GALNAC1 glycosyltransferase, which resulted in increased expression of the tumor glycoside form mucin 1 (MUC1)-sTn\textsuperscript{54}. After inhibition of MUC1, O-GlcNAcylation by C1GALT1, E-cadherin, and Fas in MUC1 positive cells was significantly increased. After the inhibition of C1GALT1, the activation of caspase-8 in MUC1 positive cells induced by exogenous Fas-L was also considerably increased. Therefore, the extensive O-GlcNAcylation of the MUC1 extracellular domain contributes to antianoikis by preventing the activation of cell surface loss initiation molecules and emphasizes the importance of O-GlcNAcylation in CRC progression and metastasis\textsuperscript{55}.

**O-GLCNACYLATION AND THERAPY FOR CRC**

With the in-depth study of protein chip, mass spectrometry, chromatography, and other technologies, the treatment related to O-GlcNAcylation has made great progress. Table 4 summarizes the therapeutic targets associated with O-GlcNAcylation and CRC.

**OGT inhibitors**

Many studies have shown that O-GlcNAcylation and OGT may be potential targets for treating cancer\textsuperscript{56}. These include analogs of the UDP-GlcNAc pathway and OGT inhibitors\textsuperscript{57}. Research has identified the biosynthetic Ac-5SGlcNAc, which can act as nucleotide sugar analogs in cells and thus block the function of OGT\textsuperscript{58}. O-GlcNAcylation may also be used as a biomarker with diagnostic or prognostic value in clinical practice. Therefore, OGT and O-GlcNAcylation in urine or blood may be helpful in the diagnosis or evaluation of treatment response. Further research on O-GlcNAcylation will continue to expand our understanding of cancer and other diseases.

OGT inhibitors may also provide new and effective drugs for treating O-GlcNAcylation. The evidence shows that BGJ398 can significantly block the effect of C1GALT1 on the malignant behavior of CRC cells and suggest that the FGF/FGFR2 signaling pathway is involved in the phenotype changes mediated by C1GALT1. Therefore, it is reasonable to speculate that other molecules may cooperate with FGFR2 to mediate the effect of C1GALT1. The identification of other receptor substrates of C1GALT1 by glycoproteomics will help reveal the detailed mechanism and behavior of C1GALT1 in regulating cancer\textsuperscript{59}. MYB proto-oncogene like 1, a transcription activator, as a downstream target, is likely to regulate CRC progression by altering O-GlcNAcylation. Related studies reveal the molecular mechanism of O-GlcNAcylation in the occurrence and progression of CRC and supports OGT as a promising target for CRC therapy\textsuperscript{60}. These findings provide new insights into the role of O-GlcNAcylation in CRC and suggest that C1GALT1 could be a target for treating CRC.

**Tn and sTn antigens**

Core 1-mediated destruction of O-GlcNAcylation depends on the exosome secretion of glycoproteins, which conversely regulates the expression of CD44 in human CRC cells and tumor-derived exosomes. Therefore, a high proportion of CD44 positive exons can be used as biomarkers to indicate abnormal O-GlcNAcylation\textsuperscript{61}. Recently, Tn antigen has attracted extensive attention in the field of tumor biology and clinical oncology. It may be a useful diagnostic marker because it is rarely found in normal tissues, but it is widely expressed in various adenocarcinoma and some malignant hematopoietic cells\textsuperscript{62}. In the first investigation of the expression of T-synthase/COSMC pathway and enzyme activity in human CRC specimens, the expression of the Tn antigen was measured. Tn antigen increased in the transmembrane region and tumor. This not only supports the report that Tn and sTn antigens are prevalent in CRC samples but also suggests that the occurrence of intracellular Tn and sTn is an early event of CRC. Other studies have also confirmed the existence of Tn antigen in gastrointestinal nonmalignant lesions such as polyps and abnormal crypt lesions\textsuperscript{63}. Therefore, Tn and sTn antigens may become potential biomarkers for prediction or early detection of human CRC, which can lead to an effective antitumor treatment response. The Tn antigen is related to the metastasis of tumor cells, and the invasiveness of the tumor is
Table 4 Therapeutic targets associated with O-GlcNAcylation and colorectal cancer

| Target/Drug                  | Binding site/Pathway                      | Result                                                                 |
|-----------------------------|------------------------------------------|-------------------------------------------------------------------------|
| Ac-5SGlcNAc                 | HBP                                      | Form UDP-5SGlcNAc, and greatly decrease O-GlcNAc levels in CRC          |
| BGJ398                      | FGF/FGFR2 signaling pathway              | Block the effect of C1GALT1 on the malignant behavior of CRC cells.    |
| MYBL1                       |                                          | C1GALT1 could be a target for treating CRC                             |
| sTn antigen                 | Core 1-mediated O-glycans biosynthesis   | Synthesize more truncated CD44 proteins                                 |
| Tn antigen                  | T-synthese/COSMC pathway                 | Play an essential part of the design of therapeutic carbohydrate       |
| TAG-72                      |                                          | conjugate antitumor vaccine                                            |
| VFA and PNA lectins         | FGFR2                                    | Targeting C1GALT1 is a promising strategy to reduce the number of     |
| SIRT1                       |                                          | CRC tumor stem cells                                                   |
| GalNAc-T6                   | GAPDH-C150                               | The binding of SNO-GAPDH to SIRT1 was selectively prevented in vitro   |
| NHEJ inhibitors             |                                          | Regulate DNA repair                                                     |
| mAbs B72.3 and CC49[22]     | TAG-72                                   | To help develop anti-Tn targeting vaccines                              |

COSMC: Core 1 β3-galactosyltransferase; CRC: Colorectal cancer; FGF: Fibroblast growth factor; FGFR2: Fibroblast growth factor receptor 2; HBP: Hexosamine biosynthetic pathway; MHC: Major histocompatibility complex; MYBL1: MYB proto-oncogene like 1; OGT: O-linked N-acetylglucosamine transferase; PNA: Peanut agglutinin; STn: Sialic acid Tn; VVA: Vicia villosa.

Complex carbohydrate modifications occur mainly on proteins on the surface of cells, which can be directly contacted by antibody-based therapies, leading to endogenous immune effector cells to tumor lesions. Evidence shows that tumor growth ability exists in a small subset of cells called cancer initiation cells or cancer stem-like cells[66]. These cells are more resistant to chemotherapy and radiotherapy[67]. Therefore, eliminating cancer stem cells is the key to effective treatment. Inhibition of the expression of C1GALT1 can reduce the ability of CRC cells to form spheres, which indicates that targeting C1GALT1 is a promising strategy to reduce the number of cancer stem cells in CRC. FGFR2 can be inhibited by Vicia villosa and peanut agglutinin lectins. The removal of sialic acid enhances the binding of FGFR2 to FGFR2, which indicates that FGFR2 carries short O-glycans such as Tn and sTn in colon cancer cells. In addition, the expression of C1GALT1 can affect the binding of Vicia villosa to FGFR2 and regulate the phosphorylation of FGFR2, which further proves that FGFR2 is O-GlcNAcylated. The NETOGLYC4.0 server predicted four potential O-GlcNAcylation sites in the extracellular domain of FGFR2[68]. The results showed for the first time that FGFR2 is O-GlcNAcylated, and O-GlcNAcylation can regulate the activity of FGFR2 in CRC cells.

directly related to the density of antigens, such as the degree of tissue diffusion and vascular invasion[64]. Therefore, this antigen is an essential part of the design of therapeutic carbohydrate conjugate antitumor vaccine for selective tumor eradication[69].

Carbohydrate modification

Complex carbohydrate modifications occur mainly on proteins on the surface of cells, which can be directly contacted by antibody-based therapies, leading to endogenous immune effector cells to tumor lesions. Evidence shows that tumor growth ability exists in a small subset of cells called cancer initiation cells or cancer stem-like cells[66]. These cells are more resistant to chemotherapy and radiotherapy[67]. Therefore, eliminating cancer stem cells is the key to effective treatment. Inhibition of the expression of C1GALT1 can reduce the ability of CRC cells to form spheres, which indicates that targeting C1GALT1 is a promising strategy to reduce the number of cancer stem cells in CRC. FGFR2 can be inhibited by Vicia villosa and peanut agglutinin lectins. The removal of sialic acid enhances the binding of FGFR2 to FGFR2, which indicates that FGFR2 carries short O-glycans such as Tn and sTn in colon cancer cells. In addition, the expression of C1GALT1 can affect the binding of Vicia villosa to FGFR2 and regulate the phosphorylation of FGFR2, which further proves that FGFR2 is O-GlcNAcylated. The NETOGLYC4.0 server predicted four potential O-GlcNAcylation sites in the extracellular domain of FGFR2[68]. The results showed for the first time that FGFR2 is O-GlcNAcylated, and O-GlcNAcylation can regulate the activity of FGFR2 in CRC cells.
Short O-glycans are usually found in CRC. These carbohydrates are associated with tumor progression and have been developed as vaccines for cancer treatment\[^{[49]}\]. Similarly, antibody-based therapies designed explicitly for tumor-associated O-GlcNAcylation will significantly increase the effective concentration of conjugated toxic antitumor drugs, thus enhancing the specificity of chemotherapy methods. In addition, vaccine methods using tumor-specific carbohydrates have the same ability to induce antitumor antibodies that promote immune memory against common tumor O-GlcNAcylation, thereby enhancing immune monitoring\[^{[69]}\]. Although vaccination may indeed induce significant immunity to cancer-related carbohydrate antigens, such immunity may create selective pressures to develop tumor lesions independently of specific carbohydrate antigens.

**SIRT1 longevity gene**

Although the relevance of SIRT1 as a longevity gene has always been controversial, silent mating type information regulation 2 homolog (SIRT1) promotes cells to protect cells in the stress response by regulating the activities of their target enzymes and transcription factors, thus affecting their lifespan\[^{[50]}\]. Small molecule SIRT1 activation can physically delay aging and prevent age-related diseases. Regulating SIRT1 O-GlcNAcylation is a potential new drug to prevent aging diseases and prolong a healthy life span. Lavrsen et al\[^{[50]}\] provided comprehensive information on cellular, transcriptional, and glycoproteomic changes caused by the expression of a single GalNAcT\[^{[50]}\]. It is important to investigate whether GalNAcT6 affects the structure of secretory organs (through its effect on melanoma inhibitory activity member 3) and glycan structure, which is deemed a factor in cell proliferation and invasion in other cell culture systems\[^{[50]}\]. To be more precise, this study highlights the role of O-GlcNAcylation in health and CRC, and much remains to be found.

**Cancer metabolic reprogramming**

Cancer metabolic reprogramming associated with increased glucose and glutamine metabolic characteristics in advanced cancer is usually attributed to a higher demand for metabolic intermediates required for the rapid growth of tumor cells. Glucose and glutamine metabolites also act as substitutes for chromatin modifiers and cofactors of other protein post-translational modifying enzymes in cancer cells. In addition to the epigenetic mechanisms that regulate gene expression, many chromatin-modifying factors also regulate DNA repair. O-GlcNAcylation is a common way to increase glucose and glutamine metabolism, drive double-strand break repair, and resistance to treatment-induced cancer cell senescence\[^{[72]}\]. Proteomic analysis showed that the DNA damage response pathway was abolished in O-GlcNAcylation-altered CRC cells. Promoting O-GlcNAcylation by targeting O-GlcNAc or simply treating animals with GlcNAc can protect CRC xenografts against radiation. In turn, the inhibition of O-GlcNAcylation by blocking the O-GlcNAc transferase activity resulted in delayed double-strand break repair, decreased CRC cell proliferation, and increased cell senescence\[^{[76]}\]. Therefore, the critical link between cancer metabolic reprogramming, DNA damage response, and aging provides a basis for evaluating targeted O-GlcNAcylation drugs to restore CRC sensitivity to radiotherapy. Considering the complexity of glycosylation sites and the complexity of glycosylation sites, the complete characterization of tumor glycans and glycoproteomics is a challenge.

**Lectin and sugar coding**

The inclusion of lectins in a microarray can be used for high-throughput analysis of glycoconjugates, and their application in clinical samples can be used as a new diagnostic tool for cancer. Lectins can be used not only to analyze cancer-related markers in serum but also to monitor O-GlcNAcylation changes in blood cells or to conduct histochemistry and cell counting will enhance the systematic analysis of sugar code in CRC patients and reveal the immune status of the tumor microenvironment\[^{[73]}\]. Glycobioinformatics is essential for revealing the sugar coding, which can better understand the polysaccharide lectin interaction between tumor and immune system, which may lead to the design of improved antitumor immunotherapy. For example, this information can be used to develop new tumor carbohydrate-specific antibodies or to improve future combination therapies. The development of new strategies for tumor glycoencoding may ultimately benefit patients who do not respond to current immunotherapy regimens. Therapeutic modifications encoded by glucose, such as blocking sialic acid with metabolic mimics or glycosidases attached to tumor-targeted antibodies, inhibit tumor growth\[^{[74]}\]. This inhibition is due to the enhanced antitumor
response mediated by T cells and the increased activity of natural killer cells, which may be due to the reduction of SIGLEC5 triggering on these cells. The specific blocking antibody against lectin receptor or tumor-specific polysaccharides can selectively inhibit the interaction between leptin and polysaccharide, which can be used locally as a new immunotherapy.

**Dendritic cells**
As a target, dendritic cells (DCs) have recently become an interesting method to induce antitumor immunity. Targeting DCs with glycan-modified tumor antigens can improve the tumor-specific T cell response and long-term tumor regression. The power of cancer vaccines is demonstrated when combined with immune checkpoint blocking[81]. Some studies have shown that changes in O-GlcNAcylation during tumorigenesis can help deceive the immune system. For example, CRC cells express a large number of MUC1 and carcinoembryonic antigen (CEA) proteins that exhibit abnormal O-GlcNAcylation, are recognized by C-type lectin receptors expressed on DCs, and regulate the innate and adaptive tumor immune responses. Therefore, the interaction between macrophage galactose lectin (MGL) and Tn epitope on MUC1 indicates that DCs drive the type 2 helper T cells-mediated response and are not involved in tumor eradication compared with Th1 effector cells[82]. DC-dependent uptake of MGL containing Tn epitope antigen enhanced major histocompatibility complex II and I expression and triggered T cell responses[83]. Similar to MUC1/MGL interaction, tumor-specific CEA and CEACAM1 proteins that specifically express Lewis antigens promote their recognition through dendritic cell-specific intercellular adhesion molecule-3-grabbing non-integrin, thus impairing DC maturation and increasing the secretion of the immunosuppressive cytokine IL-10. In the tumor microenvironment, both membrane-bound and soluble forms of CEA were expressed, which showed O-GlcNAcylation changes. Since CEA can be detected in the sera of patients with CRC, it can be speculated that this glycoprotein will damage the function of DCs far away from the tumor. O-GlcNAcylation of malignant tumors can also inhibit the function of natural killer cells, cytotoxic T cells, and macrophages from escaping their responses[84]. In the future, the individualized carbohydrate code of the tumor may destroy the immune state of the tumor by changing the O-GlcNAcylation of CRC and become the target of interference of glycan checkpoint. Alternatively, these new checkpoint blockers can be combined with DC-targeted vaccination strategies to achieve the best success of future immunotherapy regimens.

**Immune evasion**
Tumor growth is accompanied by tumor escape of the immune system, which is promoted by immune checkpoint molecules such as programmed cell death protein 1 (PD-1)[85]. PD-1 evades antitumor immunity by inhibiting T cell activation signals. The PD-1/PD-ligand 1 blockade enhanced the induction, expansion, and survival of antitumor T cells[86]. However, although abnormal tumor O-GlcNAcylation changes the way the immune system perceives tumors and can induce immunosuppressive signals through glucose-binding receptors, the role of tumor O-GlcNAcylation in immune evasion is largely ignored. Therefore, the specific polysaccharide markers found on tumor cells can be considered a new type of immune checkpoint. Most cancers have O-GlcNAcylation. The glycosylation chain becomes shorter, which is characterized by the increased expression of Tn antigen and the loss of Core-2 structure[87]. O-GlcNAcylation changes the interaction between O-glycans and carbohydrate-binding proteins and leads to the malignant phenotype, metastasis, and immune escape[88]. Simultaneously, O-GlcNAcylation of tumor protein produces new antigens, which can be used as targets of tumor-specific T cells[89]. Obviously, abnormal O-GlcNAcylation adds another layer of complexity to the new antigenicity of the tumor, and the properties of tumor-infiltrating T cells need further study. Future experiments aimed at characterizing glycopeptide major histocompatibility complex I complexes expressed by tumor cells may identify new tumor-specific epitopes that can be used as a target for glycopeptide-specific T cells[90]. Epigenetic mechanism may be involved in the regulation of CRC progression through O-GlcNAcylation.

**Notch receptor**
Studies have shown that NOTCH signaling plays an essential and diverse role in the regulation of CRC proliferation, and there may be a potential regulatory mechanism[91]. It was shown that baicalin and curcumin induced apoptosis of CRC cell line SW480 by inhibiting the NOTCH1 signaling pathway[92]. Chu et al[93] demonstrated that overexpression of NOTCH 4 could inhibit the proliferation, migration, and
invasion of CRC cells and induce apoptosis\(^9\). NOTCH signaling can regulate the apoptosis of CRC through O-GlcNAcylation and is an indicator to predict the overall survival rate of CRC patients\(^{9,11}\). Sunitinib is a multi-target antitumor signal transduction pathway. The results showed that with the increase of sunitinib concentration, the expression of NOTCH 1 protein in SW480 cells was significantly decreased. The expression levels of NOTCH 4, p53, N-MYC downstream regulated gene 4, and B cell lymphoma-associated X were significantly increased, suggesting that sunitinib inhibited SW480 by inhibiting the expression of NOTCH 1 protein and promoting the expression of NOTCH 4, p53, N-MYC downstream regulated gene 4, and B cell lymphoma-associated X. However, the specific regulatory mechanism needs to be further studied\(^{87}\). Although great progress has been made since the first sequencing of the NOTCH gene, some aspects of the NOTCH signaling pathway, although widely studied so far, remain to be fully understood\(^{91}\). O-GlcNAcylation is an essential modification of NOTCH activation and regulation. The effect of O-GlcNAcylation on NOTCH indicates the direct effect of O-GlcNAcylation on protein function. The ability to manipulate these glycans to regulate the activity of NOTCH may provide a new research tool or potential treatment of NOTCH-related diseases\(^{92}\). Checkpoint kinase (CHK) 1 and CHK2 CHK1 and CHK2 are still critical therapeutic targets. Targeting CHK1 and CHK2 destroys the stability of OGT and contributes to the therapeutic potential of targeting these kinases. O-GlcNAc acts as a critical regulator of intestinal stem cells/enteroblasts homeostasis by regulating DNA damage response. In particular, OGT can induce and respond to the DNA damage response pathway. Stress first causes DNA damage, induces a DNA damage response pathway, and then increases O-GlcNAc. However, there is only one gene mutation in O-GlcNAcase, the DNA damage response is induced, and O-GlcNAc is necessary for stress-mediated DNA damage response\(^{43}\). CONCLUSION As a post-translational modification, O-GlcNAcylation plays a complex regulatory role in CRC\(^{93-112}\). Although the research on the relationship between O-GlcNAcylation and CRC has made progress, it is obvious that only the tip of the iceberg has been revealed. However, the close relationship between O-GlcNAcylation and the abnormal metabolism of CRC is undeniable. Therefore, an in-depth study of O-GlcNAcylation is imperative. Future research will provide new ideas and directions for the development of antitumor drugs and the discovery of new diagnostic markers and therapeutic targets of CRC.

ACKNOWLEDGEMENTS
