Automatically enriching spoken corpora with syntactic information
for linguistic studies

Abstract

Syntactic parsing of speech transcriptions faces the problem of the presence of disfluencies that break the syntactic structure of the utterances. We propose in this paper two solutions to this problem. The first one relies on a disfluencies predictor that detects disfluencies and removes them prior to parsing. The second one integrates the disfluencies in the syntactic structure of the utterances and trains a disfluencies aware parser.

Keywords: speech processing; parsing; syntactic annotation

1. Introduction

Corpus-based linguistic studies require large amounts and a wide variety of syntactically annotated corpora. In this paper, we present some results on the automatic syntactic annotation of spoken corpora containing spontaneous speech. This study takes place in the framework of the ORFEO project. The goal of this project is to provide to the scientific community access to a large number of spoken and written corpora annotated with a common scheme to facilitate linguistic studies across genre and modality (written and oral). To this purpose, in a first phase of the project, it was decided to annotate automatically all corpora with a common part of speech (POS) and syntactic dependency labels tagset. If this process is rather straightforward for written corpora, it raises two major issues when dealing with spoken corpora containing spontaneous speech. The first one concerns the notion of sentence , which is important for syntactic parsing but does not have a clear definition when dealing with speech data. The second one concerns the presence, in spoken transcriptions, of specific phenomena, often referred as disfluencies, such as filled pauses, discourse markers, repetitions, false starts, which are characteristics of spontaneous speech.

We focus in this paper on the second issue: dealing with disfluencies that break the syntactic structure of utterances, and propose two ways to deal with them: either integrate them in the syntax and learn parsers that are able to deal with them or devise a specific module that detects and removes them prior to parsing. In order to compare these two approaches we performed our experiments on the RATP-DECODA corpus. This corpus is particularly well suited to this study as it contains both very spontaneous speech and linguistic annotations (disfluencies, POS and syntactic dependencies). The models and tagging/parsing strategies trained on this corpus will be applied in a second phase to all the other ORFEO corpora.

The structure of the paper is the following: Section 2. describes the DECODA corpus and the annotation schema, section 3. describes the POS tagger used. Although tagging is not the main topic of this paper, it plays an important role both for disfluency detection and parsing. Sections 4. and 5. respectively describe the disfluency prediction module and the parser. Section 6. concludes the paper.

2. The RATP-DECODA Corpus

The RATP-DECODA corpus (Bechet et al., 2012) collected within the DECODA project is made of 2100 dialogs, corresponding to about 74 hours of sound recordings. It contains dialogs recorded at the Paris Transport Authority (RATP) call-center between operators and users of Paris public transports. The average duration of a dialog is about 3 minutes. This corpus is fully anonymized, manually segmented, transcribed and annotated.

Five levels of linguistic annotations have been performed on the transcriptions of the DECODA corpus: Disfluencies, POS tags, Syntactic dependencies, Chunks and Named Entities. Chunks and Named Entities have are not covered in this study. More details on the annotation process can be found in (Bazillon et al., 2012).

The disfluencies considered are repetitions, such as “le le” (the the), false starts, such as “bonj-” (the beginning of the word “bonjour” (good morning)) and discourse markers, such as “euh” or “bien” (well). The category discourse marker also includes the filled pauses. The repetitions considered are: single words “le le” (the the); word sequences “on est on est” (we are we are); or approximate repetitions with synonyms “je voudrais je veux” (I would like I want). False starts have been marked following the ESTER (Galliano et al., 2009) conventions for speech transcription: each false start is marked with the symbol ($) added to the part of work pronounced. For example: “met)” for “metro”.

Each word of the corpus is labelled with a disfluency label chosen among the set (REP, DM, FALSTART, NULL). 28% of the speech segments contain at least one discourse marker (or a filled pause), 8% contain a repetition and 1% contain a false start.

The ORFEO POS tagset is made of 17 tags, described in table 1. Words that are part of a disfluent expression have been assigned a POS. For example, a repetition such as: “je je je veux” (I I I want) is tagged: “CLI CLI CLI VRB”.

The ORFEO syntactic dependency labels tagset is restricted to 12 labels, described in table 2. The DISFLINK dependency is introduced in order to link disfluent words to the syntactic structure of the utterance. Disfluent words are systematically linked to the preceding word in the utterance. There is no deep
linguistic reason for this, the only aim is to keep the tree structure of the syntactic representation. When a disfluent word starts an utterance, it is linked to a phony empty word that starts all sentences. An utterance of the DECODA corpus is shown in Table 3 (yes so there are there are three uh three trains every four). The first column corresponds to the position of the token in the utterance, the second to the token itself, the third to its POS, the fourth to its disfluency status (repetition, discourse marker or regular word) the fifth indicates the position of the syntactic governor and the last one is the dependency label. This utterance contains two discourse markers, the leading oui and the hesitation euh. It also contains two repetitions, a complex one il y a and a simple one trois that is separated from its copy by the discourse marker euh. In order to train and evaluate the NLP software used in this study, the RATP-DECODA corpus has been divided into a training and a test set. This partition is presented in Table 4.

This experiment clearly shows that disfluent input can be tagged with the same accuracy as non disfluent input when the tagger is trained on disfluent data. There is therefore no need to try to remove the disfluencies prior to tagging a corpus of spoken transcriptions. It is therefore the disfluencies aware tagger that is used for the experiments in the next sections.

Table 1: The ORFEO part of speech tagset

| ADJ | Adjective |
| ADN | Negative Adverb |
| ADV | Adverb |
| CLI | Clitic |
| CLN | Negative Clitic |
| COO | Coordinating Conjunction |
| CSU | Subordinating Conjunction |
| DET | Determiner |
| INT | Interjection |
| NOM | Name |
| PRE | Preposition |
| PRO | Pronoun |
| PRQ | Relative and Interrogative Pronoun |
| VNF | Verbe Infinitive Form |
| VPP | Past Participle |
| VPR | Present Participle |
| VRB | Finite Tense Verb |

Table 2: The ORFEO dependencies label tagset

| SUJ | Subject |
| OBJ | Direct Object |
| OBL | Indirect Object |
| AUX | Auxiliary |
| AFF | Affix |
| DET | Determiner |
| MOD_REL | Relative Clause |
| MOD | Modifier |
| COORD | Coordination |
| DEP_COORD | Coordinated Element |
| ROOT | Utterance Root |
| DISFLINK | Disfluency |

Table 3: An annotated utterance from the DECODA corpus described in (Bazillon et al., 2012)

| turn nb | token nb | TOTAL | REP | DM |
|--------|----------|-------|-----|----|
| TRAIN  | 93,561   | 521,377| 15,484 | 35,183 |
| TEST   | 3,639    | 25,231 | 882  | 1692 |

Table 4: Disfluency statistics on the DECODA corpus

3. Tagging

The tagger used in this study is based on a sequential Conditional Random Field predicting the sequence of tags given features anchored at each word: word n-grams up to 3, morphological traits (prefixes and suffixes of length up to 4, capitalization, character classes) and POS tag bigrams. The model is trained with LBFGS using crfsuite (Okazaki, 2007). At decoding time, we use a lexicon of possible tags for known forms and allow the prediction of any tag for unknown forms. Table 5 reports the result of the tagging experiment. The first column indicates whether the tagger was trained on a corpus where the disfluencies have been kept (DISF) or removed (NODISF).

The second column specifies whether the test corpus contains disfluencies or not. The third, fourth, fifth and sixth columns indicate respectively parsing accuracy on the whole test corpus (TOTAL), on the non disfluent tokens of the corpus (NULL), on the repetition disfluencies (REP) and on discourse marker disfluencies (DM).

The results show that the disfluencies aware tagger gives better results on the test corpus with disfluencies or not. The third, fourth, fifth and sixth columns indicate respectively parsing accuracy on the whole test corpus (TOTAL), on the non disfluent tokens of the corpus (NULL), on the repetition disfluencies (REP) and on discourse marker disfluencies (DM).

The results show that the disfluencies aware tagger gives better results on the test corpus with disfluencies, which does not come as a surprise. They also show that the disfluencies aware tagger behaves well on non disfluent parts of the corpus. This experiment clearly shows that disfluent input can be tagged with the same accuracy as non disfluent input when the tagger is trained on disfluent data. There is therefore no need to try to remove the disfluencies prior to tagging a corpus of spoken transcriptions.
Table 5: Tagging accuracy according to whether the model is trained on disfluent speech or not, and broken down by disfluency category.

|        | TRAIN | TEST | TOTAL | NULL | REP | DM |
|--------|-------|------|-------|------|-----|----|
| NODISF| NODISF| 97.27|       |      |     |    |
| DISF   | DISF  | 96.38| 97.18 | 95.69| 85.81|    |

Table 6: Disfluency prediction performances for different feature sets

| Features                  | PREC | REC  | F-MEAS. |
|---------------------------|------|------|---------|
| word n-gram               | 98.1 | 76.2 | 85.8    |
| word + POS feat           | 96.7 | 81.1 | 88.2    |
| word + POS n-gram         | 97.5 | 83.5 | 89.9    |
| word + POS + rep. feat    | 96.0 | 85.1 | 90.2    |

Table 7: Parsing accuracy of a parser trained on FTB

|        | FTB | DECODA NODISF | DECODA DISF |
|--------|-----|---------------|-------------|
| 1st order | UAS | 87.92 | 71.01 | 65.78 |
|         | LAS | 85.54 | 64.28 | 58.28 |
| 2nd order | UAS | 89.71 | 71.87 | 66.09 |
|         | LAS | 87.32 | 65.30 | 58.70 |

5. Parsing

Three series of experiments have been conducted with respect to syntactic parsing. The first one corresponds to the situation where we do not have access to a syntactically annotated dialog corpus. In the second situation we have access to a dialog corpus that has been annotated with POS and disfluency tags and in the third situation we have at our disposal a syntactically annotated dialog corpora on which a parser can be trained.

The parser used for these experiments is a graph based parser (McDonald et al., 2005) implemented in the MACAON tool suite (Nasr et al., 2011). It is a parser that produces dependency trees. For a given sentence, the parser considers all its possible projective dependency trees and selects the tree that maximizes a score. In its simplest form (called first order), the score of a tree is the sum of the scores of every dependency that make up the tree. The score of a dependency is itself the sum of the weights of the features that correspond to this dependency. Feature weights are learned from training data using the perceptron algorithm. A more sophisticated scoring function, known as second order, computes the score of a tree as the sum of scores of subtrees made of one or two dependencies. Second order models usually yield better results than first order ones at the cost of higher computational complexity. Two standard metrics are used to measure the quality of the syntactic trees produced by the parser. The Unlabeled Attachment Score (UAS) which is the proportion of words in a sentence for which the right governor has been assigned by the parser and the Labeled Attachment Score (LAS) which also takes into account the label of the dependency that links a word to its governor.

In the three subsection below we describe experiments corresponding to the three scenarios described above.

5.1. Training on written material

In this experiment, the parser has been trained on the training set of the French Treebank (FTB) (Abelléil et al., 2003). The FTB corpus is a collection of newspaper articles from the French journal Le Monde. It is therefore quite different from the genre of data that we want to parse. The parser has been evaluated on three corpora: the test set of the FTB (for sanity check), the test set of the DECODA corpus without disfluencies and the test set of the DECODA corpus with disfluencies. It must be noted that the second experiment (predicting parse trees on the test set of the DECODA corpus without disfluencies) is artificial since the disfluencies have been manually removed from the corpus. It represents an upper bound of the parsing accuracy if we had at our disposal a perfect disfluency predictor.

The results are reported in Table 7.
Table 7 shows that while the performances of the parser are state of the art on the FTB test set, they drop sharply for the DECODA corpus without disfluencies and continue to drop for the DECODA corpus with disfluencies. This does not come as a surprise since the parser is evaluated on corpora that are further and further away from the FTB training corpus. The table also shows that second order models behave better on all corpora, although the difference is more important on written corpora.

5.2. Automatically removing disfluencies
In this experiment, the parser has been trained, as before, on the FTB corpus and is evaluated on the DECODA corpus from which disfluencies have been automatically removed using the disfluency predictor described in Section 4. Results are reported in Table 8 (columns DECODA NODISF and DECODA DISF have been reproduced from Table 7 for readability purpose).

|       | DECODA AUTO | DECODA NODISF | DECODA DISF |
|-------|--------------|----------------|------------|
| 1st order | UAS 71.66 | 71.01 | 65.78 |
|        | LAS 65.19 | 64.28 | 58.28 |
| 2nd order | UAS 72.29 | 71.87 | 66.09 |
|        | LAS 65.88 | 65.30 | 58.70 |

Table 8: Parsing accuracy computed on the DECODA corpus from which disfluencies have been automatically removed.

Table 8 shows that the strategy of automatically removing the disfluencies prior to parsing is an interesting one. The LAS jumps from 58.28 to 65.19 for second order models. It must be noted that the results on DECODA DISF and DECODA AUTO are directly comparable since after parsing, the disfluencies that have been automatically detected and removed are reintroduced in the output of the parser and linked to the preceding word with a DISF dependency, as described in Section 2.

5.3. Training on the DECODA corpus
In this last series of experiments, the parser is trained on the DECODA corpus and evaluated on our four test corpora. The evaluation on the FTB corpus is not directly relevant to our purpose, it has been added for completeness. The results are reported in Table 9.

|       | DECODA AUTO | DECODA NODISF | DECODA DISF |
|-------|--------------|----------------|------------|
| 1st order | UAS 85.90 | 86.47 | 85.83 | 77.93 |
|        | LAS 83.86 | 84.00 | 83.62 | 73.80 |
| 2nd order | UAS 85.63 | 86.07 | 85.62 | 77.25 |
|        | LAS 83.61 | 84.19 | 83.56 | 73.20 |

Table 9: Parsing accuracy of a parser trained on DECODA.

This table shows several interesting features. The first one is that the parser trained on the DECODA corpus yields much better results than a parser trained on the FTB corpus even when disfluencies are removed. The LAS jumps from 65.19 to 83.86. Two reasons can explain this result. The first one is that the DECODA corpus has a quite restricted and specific vocabulary and the parser used is quite good at learning lexical affinities.

The second one is that the DECODA corpus has a rather simple syntax with utterances generally restricted to simple clauses and less common ambiguities, such as prepositional attachment and coordination, than written texts.

The rather simple syntax of the DECODA corpus also explains that first order models behave as well as second order ones, as shown in Table 9.

In this experiment, besides parsing, the parser acts as a disfluency predictor since every dependent of a dependency labeled DISFLINK is considered as a disfluency by the parser. The prediction of the parser on this task has a recall of 71.49, a precision of 88.00 and an F-measure of 78.89. It is interesting to compare these scores with the scores of the disfluency predictor of Section 4. which had a recall of 94.1, a precision of 96.9 and an F-measure of 95.5. The predictions of the parser are therefore significantly lower than the predictions of the disfluencies predictor. The poor results obtained by the parser as a disfluencies predictor might be due to the fact that the parser is not good at detecting repetitions, which account for 35% of the disfluencies, whereas the disfluencies predictor has specific features that model repetitions. The low accuracy of disfluencies detection explains that the accuracy of the disfluencies aware parser on the DECODA test set from which disfluencies have been automatically removed is higher than the accuracy of the same parser on the DECODA test set with disfluencies.

In the last experiments, a parser is trained on the non disfluent part of the DECODA corpus. The results are reported in Table 10. As expected, the parser behaves poorly on the DECODA test set but its performances are better on the AUTO corpus (LAS = 83.45 UAS = 85.52). These figures can be directly compared with the performances of the disfluencies aware parser evaluated on the DECODA test set (LAS = 83.86 UAS = 85.90). As one can see, the performances are very close.

|       | DECODA | FTB |
|-------|--------|-----|
| 1st order | AUTO 85.52 | NODISF 86.50 | DISF 80.08 | FTB 77.71 |
|        | LAS 83.45 | 84.70 | 77.87 | 73.67 |
| 2nd order | AUTO 85.03 | 86.06 | 79.61 | 76.77 |
|        | LAS 82.96 | 84.26 | 77.40 | 72.76 |

Table 10: Parsing accuracy of a parser trained on DECODA without disfluencies.

6. Conclusions
We have shown in this paper that high accuracy parsing can be performed on spontaneous speech despite disfluencies. Two methods have been proposed and evaluated. In the first one a disfluency predictor is run on a test corpus. The detected disfluencies are then removed and the corpus is sent to the parser. In the second one, a parser is trained on a syntactically annotated corpus containing disfluencies. The test corpus with disfluencies is then parsed with the disfluencies aware parser. In
this setting, parsing and disfluencies detection are performed jointly by the parser. The performances of the two methods are very close. This process has been tuned on the RATP-DECODA, it is now applied to all the other spoken corpora of the ORFEO project.

7. Acknowledgments

This work has been funded by the French Agence Nationale pour la Recherche (ANR), through the project ORFEO (ANR-12-CORP-0005).
