Abstract

The purpose of this study was to determine naproxen concentrations in rat plasma samples by HPLC and to compare the bioavailability of a generic and two compounded naproxen sodium suspensions (test 1 and test 2). Analysis was run at a flow rate of 1.2 mL min⁻¹ with a mobile phase of acetonitrile: NaH₂PO₄ 0.01 M pH 4.00 (50:50, v/v) at 280 nm, using a C₁₈ column (150 mm x 4.6 mm, 5 μm). The calibration curve was linear (R² = 0.9987) over the range of 0.25 - 200 μg mL⁻¹. The precision for intra- and inter-day analysis ranged from 2.46% to 12.39%. Cmax, Tmax, and AUC were 191.25 ± 11.17 μg mL⁻¹, 1.00 ± 0.106 h and 2438.16 ± 291.34 μg h mL⁻¹ for the reference drug, 188.22 ± 24.78 μg mL⁻¹, 1.06 ± 0.092 h and 1755.02 ± 228.90 μg h mL⁻¹ for test 1, and 160.50 ± 10.58 μg h mL⁻¹, 0.66 ± 0.102 h and 1955.28 ± 142.80 μg h mL⁻¹ for test 2. No significant differences were found based on analysis of variance, with mean values and 90% CI of test2/reference ratio (Cmax 83.92% and AUC 80.19%). For test1/reference ratio, the result was Cmax 98.41% and AUC 71.98%. Based on these results, it can be concluded that the validated method was successfully applied to this study; the test 1 formulation failed to demonstrate a bioequivalence to the reference drug; however, the test 2 and reference naproxen sodium suspension were bioequivalent in terms of the rate and extent of absorption under these conditions.

Keywords: Bioavailability studies; Validation; HPLC; Pharmacokinetics; Compounded naproxen sodium suspension

Introduction

According to Anfarmag (Associaçao Nacional de Farmaceuticos Magistrais) the turnover of compounded medicines is very high in Brazil. In 2008, the sales amounted to R$1.2bil (Redação Anfarmag, 2009). The large consumption of these medicines by the Brazilian population has raised the suspicion of the quality and safety of these drugs, since cases of toxicity and death were reported by the National Agency of Health Vigilance (ANVISA, 2008). Compounded naproxen sodium suspension is highly used by the children in Brazil (Redação Anfarmag, 2009). This over-the-counter (OTC) drug is safety but these compounded medicines have possible risks of variable bioavailability due to differences among formulations. Despite frequent inspections of Brazilian compounding pharmacies, there is not a strict quality control that involves in vivo tests.

Structurally naproxen is a propionic acid derivative related to the arylacetic group of nonsteroidal anti-inflammatory drugs (NSAIDs) (Valentovic, 2008). Member drugs of the NSAID group act by inhibiting prostaglandin biosynthesis and share several adverse effects including gastrointestinal bleeding and ulceration (Boynton et al., 1986; Brodgen et al., 1979; Aronson, 2006; Marta et al., 2007). Several high-performance liquid chromatography (HPLC) methods have been developed for naproxen determination in human or rat plasma for pharmacokinetic studies (Cakrt et al., 2001; Costi et al., 2008; Attia, 2009; Hearan Suh et al., 1995; Farrar et al, 2002; Martin, 1999; Paino et al, 2005; Zakeri-Milani et al, 2005). Nevertheless, there is a need to improve these methods in terms of ease of sample handling and analysis time. Many naproxen products are used in worldwide, but there is no bioavailability data concerning naproxen compounded formulations.

The aim of this study was to determine naproxen concentrations in rat plasma samples and to investigate the pharmacokinetic parameters of three different oral suspensions of naproxen sodium (one manufactured suspension and two compounded formulations) in order to compare their bioavailability.

Experimental

Chemicals and reagents

The reference material naproxen with a purity 100.3% was purchased from DEG Importação de Produtos Quimicos LTDA, Brazil. The internal standard, diclofenac sodium [2-2(2, 6-dichlorophenylamino) phenyl] acetic acid] with a purity 99.6% was obtained from All Chemistry Produtos Naturais & Farmacêuticos, Brazil. All other chemicals were of HPLC grade. Milli-Q water (Millipore Corporation, Bedford, MA) was used for NaH₂PO₄ buffer preparation. The generic naproxen formulation (25 mg mL⁻¹) was produced by Syntex S.A., Mexico. The two test naproxen sodium oral suspensions, test 1 (suspension A, 25 mg mL⁻¹) and test 2 (suspension B, 25 mg mL⁻¹) were obtained from two different compounding pharmacies, A and B respectively, in Natal, Brazil.

Equipment and analysis conditions

Analyses were performed with a Varian ProStar HPLC system

Bioscience Center of Universidade Federal do Rio Grande do Norte
UV 280 nm and the injection volume was 20 \( \mu \)L. The detection wavelength was set at

Stock and working standard solutions

The stock solution of naproxen (1 mg mL\(^{-1}\)) and the internal
standard (1 mg mL\(^{-1}\)) were prepared by dissolving the appropriate
amount of the pure solid in acetonitrile. Both stock solutions were
stored in a – 80ºC freezer. The working standard solutions of
naproxen were prepared fresh by step-wise dilutions of the above
stock solution with the mobile phase to provide a calibration
concentration range of 0.25 – 200 \( \mu \)g/mL when spiked into drug-
free rat plasma. The working internal standard solution was prepared from the stock by dilution with mobile phase to 50 \( \mu \)g/mL.

Four quality control samples (QC), were prepared from the stock
solutions by spiking naproxen into drug-free rat plasma to obtain final
concentrations of 0.5, 15, 75 and 150 \( \mu \)g mL\(^{-1}\). Routine calibration
curves consisting of 0.25, 1, 5, 10, 20, 40, 100 and 200 \( \mu \)g mL\(^{-1}\)
calibrators were generated together with the QC for computation
of naproxen concentrations in rat samples using peak area ratios of
naproxen and internal standard.

Animals handling and sample collection

Wistar rats weighing 280 – 300 g were obtained from the Bioscience Center of Universidade Federal do Rio Grande do Norte
(Natal, Brazil). They were acclimated and housed in cages at a
temperature of 25°C with free access of standard laboratory food
and water. Twelve hours before the initiation of experiments, food
was withheld, but animals had free access to water. All handling
and experimentation were according to protocols approved by the
institutional care and use of laboratory animals committee.

Naproxen sodium suspension was orally administered to rats at a

dose of 50 mg kg\(^{-1}\). The animals were anesthetized with 15 mg kg\(^{-1}\)
of xilazine hydrochloride (20 mg mL\(^{-1}\)) and 100 mg kg\(^{-1}\) of ketamina
hydrochloride (50 mg mL\(^{-1}\)) through an i.p. route. Blood samples were
taken from the tails at time intervals of 10, 20, 40, 60 min, 3, 4, 6,
24 and 48 h. At each time point, blood samples were collected from
five rats to compute the mean concentration. Since only a maximum
of 3 - 4 samples of 500 µL each could be sampled from a rat over a
short time, three groups of five rats were needed to complete the full
sampling intervals. The blood samples were collected into heparin-
coated tubes and maintained on ice for a short time before spinning
in a microcentrifuge at 4°C to harvest the plasma samples, which
were immediately stored at – 80°C until analysis.

Clean up of plasma samples

150 µL of plasma obtained from dosed animals was mixed with
25 µL of internal standard solution, 50 µL of NaH\(_2\)PO\(_4\) 0.5 M pH 2.2
and NaCl for 1 minute. 250 µL of acetonitrile was then added and the
sample vortexed for 3 minutes. For the calibration and quality control
samples, 25 \( \mu \)L of their respective working standards prepared in
acetonitrile : NaH\(_2\)PO\(_4\) 0.01 M pH 4.00 (50:50, v/v) were added to
each 150 \( \mu \)L of free-drug plasma before mixing with internal standard
solution. NaCl and acetonitrile in the mixture precipitated the plasma
proteins. The mixture was then centrifuged at 10,000 rpm at 4°C for
5 minutes, and the supernatant containing the extracted naproxen
and the internal standard was then filtered through 0.45 µm and
transferred to the auto-sampler of the HPLC for analyses.

Method validation

The method was validated according to the “Guidance for
Industry” under the section of “Bioanalytical Method Validation” by
the Food and Drug Administration of USA (FDA, 2001).

Selectivity and linearity

The selectivity of the method was assessed by determining that
endogenous substances and the anesthetics present in rat plasma do
not co-elute with naproxen and the internal standard in the HPLC
method.

Normal and hemolysate plasma samples from at least six untreated
rats were used to verify the selectivity of the bioanalytical method.

To evaluate the linearity of the calibration curves, eight calibration
standards containing naproxen at nominal concentrations of 0.25,
1, 5, 10, 20, 40, 100 and 200 \( \mu \)g mL\(^{-1}\) were prepared as described
in section 2.3. The standard calibration curves were constructed
using naproxen/external standard peak-area ratios vs. the nominal
concentration by linear regression.

Precision, accuracy and recovery

Assay precision was assessed by determining the coefficients of
variation (CV) of the four QC samples (concentrations of 0.5, 15, 75
and 150 \( \mu \)g mL\(^{-1}\) within the same analysis \( n=5, \) intra-day precision)
and over a series of analyses \( n=5, \) inter-day precision). Both intra-day
and inter-day precision were calculated with the following formula:

\[ CV\% = \frac{\text{standard deviation}}{\text{mean}} \times 100 \]

Relative accuracy was determined by calculating the percent
accuracy by the equation:

\[ \text{Accuracy} = \frac{\text{mean measured concentration}}{\text{nominal concentration}} \times 100 \]

The precision and accuracy of the first calibrator of 0.25 \( \mu \)g mL\(^{-1}\),
lower limit of quantification (LLOQ) were also evaluated.

The recovery experiments in this study were performed by
comparing peak areas of naproxen and internal standard in spiked
plasma samples, extracted by the method described in section 2.5.
The compounds of interest at concentrations corresponding to 100% recovery were added to similarly post-extracted blank plasma.

Stability

The stability of naproxen in rat plasma was tested in three freeze-
thaw cycles with QC samples at four concentration levels. These
samples were stored frozen at –20°C and analyzed on days 0, 1 and
5 to give the evaluations.

Specifically, the long term stability of the samples when stored at
–80°C for up to 4 months was analyzed, since this is the temperature at which the samples were stored before analysis. To assess the stability of the samples between the time of extraction and the HPLC run, the samples were analyzed at the time of extraction and the values were compared to the 10 and 24 h post-extraction values of the same samples stored at room temperature. These tests provide the validation for using the auto-sampler when analyzing multiple samples.

Pharmacokinetic and statistical analyses

Pharmacokinetic analysis of naproxen was carried out according to a standard non-compartmental method using the WinNonlin software (Pharsight Co., CA, Version 2.0). $C_{\text{max}}$ and $T_{\text{max}}$ were obtained directly from the observed data. The $\text{AUC}_t$ was calculated by the trapezoidal method. The $\text{AUC}_{\infty}$ was calculated as $\text{AUC}_t + C_t/\beta$, where $C_t$ was the last quantifiable concentration, $\beta$ was the terminal elimination rate constant and was determined by least-squares regression analysis during the terminal log-linear phase of the concentration-time curve. The $T_{1/2}$ was calculated as $0.693/\beta$.

Statistical analyses of variance (ANOVA) of $\text{AUC}_t$, $\text{AUC}_{\infty}$ and $C_{\text{max}}$ were calculated after transformation of the data to their logarithmic (ln) values. Using the error variance ($S^2$) obtained from the ANOVA, the 90% confidence intervals (CI) were calculated.

Figure 1: HPLC chromatograms of blank plasma (A), hemolysate plasma (B), QC sample spiked with naproxen at 0.5 $\mu$g mL$^{-1}$ and internal standard (C), a calibrator spiked with naproxen at 100 $\mu$g mL$^{-1}$ and internal standard (D), and plasma sample 1 h after administration of naproxen (E). Peak 1: naproxen at about 4.26 minutes; Peak 2: internal standard at about 8.23 minutes.
Results

Method validation

Selectivity and linearity: The Figure 1 shows representative HPLC chromatograms. The Figure 1 D shows a steady baseline, the naproxen peak was symmetrical and well separated from the plasma peak. Naproxen and internal standard were well separated using the above described chromatographic condition with retention times of 4.26 and 8.23 min respectively. No interfering peaks from endogenous substances in the control plasma samples of different times of 4.26 and 8.23 min respectively. No interfering peaks from the above described chromatographic condition with retention peak. Naproxen and internal standard were well separated using naproxen peak was symmetrical and well separated from the plasma HPLC chromatograms. The Figure 1 D shows a steady baseline, the

Precision, accuracy and recovery: The intra-day and inter-day precision and accuracy for the plasma naproxen are summarized in Table 1. The intra-day and inter-day variability for the different QC were minimal, ranging from 2.46% to 12.39%, indicating excellent precision. Accuracies using the same QC ranged from 86.7% to 101.1%. All these variabilities were well within acceptable limits. Precision and accuracy for the LLOQ of 0.25 μg mL⁻¹ were 17.6% and 98%, respectively.

The recovery from spiked plasma was calculated by comparing peak areas with QC samples (n=3) at four different concentration levels. The mean recoveries for naproxen in four QC samples (0.5, 15, 75 and 150 μg mL⁻¹) were 74.51%, 95.16%, 96.07% and 98.69%, respectively. Recovery of the internal standard was 94.2%. The lower recovery for the 0.5 μg mL⁻¹ QC was probably due to the low concentration and loss of naproxen through non-specific binding to precipitated protein.

Stability: The results of stability of naproxen in rat plasma after three freeze-thaw cycles and the long term storage are shown in Table 2. There were no significant changes (-3.37 to +3.36%) for freeze-thaw cycles and -2.24 to -10.40% for long term stability. The samples remained within acceptable limits of precision and accuracy. These results indicated that naproxen was stable for at least 5 days in rat plasma stored at –20°C and for at least 4 months when stored at –80°C. In addition the extracted samples were stable at room temperature for the periods under which determinations were made, which were 10 and 24 h later (not shown). This is important because samples can be stored in an autosampler at room temperature until measurement without compromising the concentration of naproxen.

Pharmacokinetic evaluation

In this study, the pharmacokinetic parameters AUCₜ, AUCₜ₈ and Cₘ₉₉₉ for test2/reference for AUCₜ and Cₘ₉₉ were used to compare the formulations. The results of Cₘ₉₉ and AUCₜ were 191.25 ± 11.17 μg.mL⁻¹ and 2438.16 ± 291.34 μg.h.mL⁻¹ for reference drug, 188.22 ± 24.78 μg.mL⁻¹ and 1755.02 ± 228.90 μg.h.mL⁻¹ for test 1, 160.50 ± 10.58 μg.mL⁻¹ and 1955.28 ± 142.80 μg.h.mL⁻¹ for test 2 (Table 3).

Mean plasma concentrations versus time profiles of naproxen after administration of two tests and reference formulations in rats (n = 5) are shown in Figure 2. The mean plasma concentration-time curves of the formulations were comparable.

As showed in Table 4, the 90% confidence intervals for geometric mean ratios of test2/reference for AUCₜ and Cₘ₉₉ were within the acceptable limits (80 – 125%) of bioequivalence which implies that the bioequivalence criteria were met (FDA, 2006). For test1/reference ratio, the result was Cₘ₉₉, 98.41% and AUCₜ, 71.98%.

Discussion

For comparing the bioavailability between formulations, three groups of five animals were used for each administered formulation of naproxen sodium oral suspension. The number of animals was suitable for this pharmacokinetic study (Mathy et al., 2001). Before testing the bioanalytical method was validated to ensure the reliability of results.

The bioanalytical method described above was simple and rapid for the determination of naproxen in rat plasma. A one-step protein precipitation provided a simple, rapid and economic procedure. Other methods described in the literature use sophisticated techniques for the quantification of naproxen in biological matrices, like LC-MS, fluorescence spectroscopy and capillary electrophoresis (Mikami, 2000; Monsner and Darghouth, 2003; Murillo, 2003; Borneo, 1998; Sirisuth, 2001; Pai and Liu, 2002; Sultana et al., 2008; Vermeulen and Remon, 2000; Xiong et al., 2008; Hsu et al., 2006). Despite the high sensitivity of these techniques, there is high cost as well as a lot of time spent with clean up and extraction of drug. This HPLC analysis method showed excellent precision, accuracy, stability, specificity and recovery. Therefore, this method was suitable and applied to monitor the concentration of naproxen in rat plasma.

Table 1: Intra-day and Inter-day assays precision and accuracy for naproxen in rat plasma (n = 5).

| Nominal concentration (μg mL⁻¹) | Measured concentration (μg mL⁻¹) ± S.D. | Precision (CV%) | Accuracy (%) |

Table 3: Pharmacokinetic parameters of naproxen after oral administration of naproxen sodium suspension in rat, each value represents the mean ± S.D. (n=5).
The peak plasma concentration represents the maximum plasma drug concentration obtained after oral administration of drug. $C_{\text{max}}$ provides an indication that the drug is sufficiently systemically absorbed to provide the therapeutic response (Boynton, 1988; Aarbakke et al., 1983). In the reference and test 1 formulations, $C_{\text{max}}$ was achieved within 1 h. This value is consistent with the values previously reported by other investigators (Carrasco-Portugal, 2006; Sevelius et al., 1980). In 1972, Runkel et al. (1972) performed the first in vivo tests with naproxen that was performed in rats, dog, pig, monkey and human. In all animals species studied, the half-life of naproxen ranged from 2 to 35 hours, and in humans ranged from 10 to 17 hours. Setiawati et al. (2009) investigated the pharmacokinetic parameters of naproxen following an administration of 250 mg of naproxen sodium oral suspension in humans. They obtained values of $721.73 \pm 18.47$ for $\text{AUC}_{72\text{h}}$, $43.93 \pm 1.83$ for $C_{\text{max}}$ and $2.38 \pm 0.21$ for $T_{\text{max}}$.

In this study, the $T_{\text{max}}$ for the reference and test 1 formulations was found to be 1 h, while for test 2 formulations was 0.66 h, suggesting that a rapid absorption of naproxen from test 2 formulations is occurred.

As indicated in Table 3, the $\text{AUC}_{\text{tot}}$ value of naproxen was more than 80% compared to the value of $\text{AUC}_{\text{inf}}$ for all formulations tested (99.31%, 97.75 and 98.86 for test 1, test 2 and the reference suspension, respectively), indicating that the sampling time was
