Iso-Orthogonality and Type-II Duadic Constacyclic Codes

Yun Fan and Liang Zhang
Dept of Mathematics, Central China Normal University, Wuhan 430079, China

Abstract

Generalizing even-like duadic cyclic codes and Type-II duadic negacyclic codes, we introduce even-like (i.e., Type-II) and odd-like duadic constacyclic codes, and study their properties and existence. We show that even-like duadic constacyclic codes are isometrically orthogonal, and the duals of even-like duadic constacyclic codes are odd-like duadic constacyclic codes. We exhibit necessary and sufficient conditions for the existence of even-like duadic constacyclic codes. A class of even-like duadic constacyclic codes which are alternant MDS-codes is constructed.

Keywords: Finite field, constacyclic code, isometry, even-like duadic code, iso-orthogonal code.

MSC2010: 12E20, 94B60.

1 Introduction

The study of duadic cyclic codes was initiated due to Leon, Masley and Pless [16], and attracted many attentions, e.g. [18, 20, 11, 12, 14]. The research on duadic cyclic codes over finite fields has greatly developed, see [15, Ch.6]. Rushanan [19] generalized duadic cyclic codes to the duadic group codes, and many results about the existence of such codes, especially the duadic abelian codes, were obtained, e.g. [21, 2].

Note that most of the studies on duadic cyclic codes over finite fields consider the semisimple case, i.e., the length of the codes is coprime to the cardinality of the finite field. At that case, duadic cyclic codes are not self-dual; the key obstruction is the 1-dimensional cyclic code with check polynomial \( X - 1 \), which is invariant by any multipliers. By appending with one bit, self-dual extended cyclic codes might be obtained. It is the same for group codes, more generally, for transitive permutation codes, see [13].

Another perspective to carry the research forward is to consider constacyclic codes. Let \( F_q \) be the finite field with cardinality \( |F_q| = q \) which is a prime
power, and \( n \) be an positive integer coprime to \( q \). Let \( F_q^* \) be the multiplicative group consisting of non-zero elements of \( F_q \), and \( \lambda \in F_q^* \) with \( r = \text{ord}_{F_q^*}(\lambda) \), where \( \text{ord}_{F_q^*}(\lambda) \) denotes the order of \( \lambda \) in the group \( F_q^* \). Any ideal \( C \) of the quotient algebra \( F_q[X]/(X^n - \lambda) \) is called a \( \lambda \)-constacyclic code of length \( n \) over \( F_q \), where \( F_q[X] \) denotes the polynomial algebra over \( F_q \) and \( (X^n - \lambda) \) denotes the ideal generated by \( X^n - \lambda \). In the following we always use the three numbers \( q, n, r \) to parametrize the \( \lambda \)-constacyclic code \( C \). If \( r = 1 \) (i.e. \( \lambda = 1 \)) then \( C \) is just a cyclic code. If \( r = 2 \) (i.e. \( \lambda = -1 \)) then \( C \) is named negacyclic code.

Aydin et al [3] exhibited the BCH bound of constacyclic codes. Dinh et al [10, 9] studied constacyclic codes and showed that self-duality happens for (and only for) negacyclic codes.

Blackford [4, 5] contributed very much to the study of the duadic constacyclic codes. Let \( \mathbb{Z}_{nr} \) be the residue ring of the integer ring \( \mathbb{Z} \) modulo \( nr \). The set of roots of the polynomial \( X^n - \lambda \) is corresponding to a subset of \( \mathbb{Z}_{nr} \): \( 1 + r\mathbb{Z}_{nr} = \{1, 1+r, \ldots, 1+r(n-1)\} \). The multipliers act on this set \( 1 + r\mathbb{Z}_{nr} \). In this way, Blackford [4] obtained all self-dual negacyclic codes, introduced Type-I and Type-II (even-like) duadic splittings in the negacyclic case (i.e. \( r = 2 \)), and proved the existence of Type-II duadic negacyclic codes for the case when \( n \) is even but \( n/2 \) is odd. Further, in [5], it was shown that the Type-I duadic constacyclic codes are just the so-called \textit{iso-dual} constacyclic codes.

Type-I polyadic (including duadic) constacyclic codes were studied in [7]. In terms of Chinese Remainder Theorem, the set \( 1 + r\mathbb{Z}_{nr} \) and the multiplier group can be decomposed suitably. Necessary and sufficient conditions for the existence of such codes were obtained. Some generalized Reed-Solomon or alternant constacyclic codes were constructed from Type-I polyadic constacyclic codes.

In this paper, generalizing even-like (Type-II) and odd-like duadic negacyclic codes, we introduce even-like (i.e., Type-II) and odd-like duadic constacyclic codes, and study their properties and existence.

In Section 2, necessary notations and fundamentals are described.

In Section 3, with isometries between constacyclic codes, even-like (Type-II) and odd-like duadic constacyclic codes are defined, and a relationship between the two kinds of duadic constacyclic codes are exhibited (Theorem 3.7 below). As known, even-like duadic constacyclic codes are not self-orthogonal in general. We show that they are \textit{iso-orthogonal} and, up to some sense, they are the maximal iso-orthogonal pairs of constacyclic codes (Theorem 3.12).

For the existence of Type-I duadic constacyclic codes, a necessary and sufficient condition has been obtained in [7 Th.2.2], see Lemma 1.3(iii) below also. In Section 4, we present necessary and sufficient conditions for the existence of Type-II duadic constacyclic codes, see Theorem 4.1 below, where the cyclic case and the negacyclic case are included as straightforward consequences.

In Section 5, a class of alternant MDS-codes is constructed from even-like duadic constacyclic codes (Proposition 5.1), and some specific examples are presented.
2 Preliminaries

In this paper, $F_q$, $F_q^*$, $\lambda \in F_q^*$, $r = \text{ord}_{F_q^*}(\lambda)$, and $n$ which is coprime to $q$, are always as introduced in Section 1. Note that $|F_q^*| = q - 1$, hence $r | (q - 1)$. Following [5], we abbreviate the quotient algebra by

$$R_{n,\lambda} = F_q[X]/(X^n - \lambda).$$

(2.1)

For an ideal $C$ of $R_{n,\lambda}$, i.e., a $\lambda$-constacyclic code $C$ over $F_q$ of length $n$, we write it as $C \subseteq R_{n,\lambda}$.

In this paper we always assume that $\theta$ is a primitive $nr$-th root of unity (in a suitable extension of $F_q$) such that $\theta^n = \lambda$. As mentioned in Introduction, the set of roots of $X^n - \lambda$ is corresponding to the subset $P_{n,\lambda}$ of the residue ring $\mathbb{Z}_{nr}$, which is defined by:

$$P_{n,\lambda} = 1 + r\mathbb{Z}_{nr} = \{1 + rk \pmod{nr} | k \in \mathbb{Z}_{nr}\},$$

(2.2)

such that

$$X^n - \lambda = \prod_{i \in P_{n,\lambda}} (X - \theta^i).$$

By $\mathbb{Z}_{nr}^*$ we denote the multiplicative group consisting of units of $\mathbb{Z}_{nr}$. The group $\mathbb{Z}_{nr}^*$ acts by multiplication on $\mathbb{Z}_{nr}$. Precisely, any $t \in \mathbb{Z}_{nr}^*$ induces a permutation $\mu_t$ of the set $\mathbb{Z}_{nr}$ as follows: $\mu_t(k) = tk$ for all $k \in \mathbb{Z}_{nr}$. Any $\mu_t$-orbit on $\mathbb{Z}_{nr}$ is abbreviated as a $t$-orbit. The set of $t$-orbits on $\mathbb{Z}_{nr}$ (i.e., the quotient set by $\mu_t$) is denoted by $\mathbb{Z}_{nr}/\mu_t$. For any subset $P \subseteq \mathbb{Z}_{nr}$, the permutation $\mu_t$ transforms $P$ to the subset $tP = \{tk \pmod{rn} | k \in P\}$. We say that $P$ is $\mu_t$-invariant if $tP = P$. If $t \equiv t' \pmod{r}$ with $1 \leq t' < r$ (recall that $t$ is coprime to $r$), it is easy to see that

$$tP_{n,\lambda} = t + rt\mathbb{Z}_{nr} = t + r\mathbb{Z}_{nr} = t' + r\mathbb{Z}_{nr},$$

and $\theta^j$ for $j \in t' + r\mathbb{Z}_{nr}$ are just all roots of $X^n - \lambda^t = X^n - \lambda'$. So we denote $t + r\mathbb{Z}_{nr} = P_{n,\lambda^t}$. With this notation, for any $t \in \mathbb{Z}_{nr}^*$ we have

$$X^n - \lambda^t = \prod_{i \in P_{n,\lambda^t}} (X - \theta^i), \quad \text{where} \quad P_{n,\lambda^t} = tP_{n,\lambda}.$$  

(2.3)

Further, for any $s \in \mathbb{Z}_{nr}$, it is easy to see that $sP_{n,\lambda^t} = P_{n,\lambda^t}$ if and only if $s \in 1 + r\mathbb{Z}_{nr}$, i.e., $s \in \mathbb{Z}_{nr}^* \cap (1 + r\mathbb{Z}_{nr})$. We denote

$$G_{n,r} = \mathbb{Z}_{nr}^* \cap (1 + r\mathbb{Z}_{nr}),$$

(2.4)

which is a subgroup of the group $\mathbb{Z}_{nr}^*$. We call $G_{n,r}$ the multiplier group.

Since $r | (q - 1)$, we see that $q \in G_{n,r}$. The $q$-orbits on $\mathbb{Z}_{nr}$ are also named $q$-cyclotomic cosets (or $q$-cosets) in literature. Obviously, $P_{n,\lambda^t} = t + r\mathbb{Z}_{nr}$ for
any \( t \in \mathbb{Z}_{n^r}^* \) is \( \mu_q \)-invariant. For any \( q \)-orbit \( Q \in P_{n,\lambda}/\mu_q \), the polynomial \( f_Q(X) = \prod_{i \in Q} (X - \theta^i) \) is irreducible in \( F_q[X] \). Thus

\[
X^n - \lambda^t = \prod_{Q \in P_{n,\lambda}/\mu_q} f_Q(X)
\]

is the monic irreducible decomposition in \( F_q[X] \).

For any \( \mu_q \)-invariant subset \( P \) of \( P_{n,\lambda} \), We have a polynomial

\[
f_P(X) = \prod_{Q \in P/\mu_q} f_Q(X) \in F_q[X].
\]

Let \( \overline{P} = P_{n,\lambda} \setminus P \) (which denotes the difference set), i.e., \( \overline{P} \) is the complement of \( P \) in \( P_{n,\lambda} \). By Eqn (2.5),

\[
f_P(X)f_{\overline{P}}(X) = X^n - \lambda. \tag{2.6}
\]

**Remark 2.1.** It is well-known that for any \( \lambda \)-constacyclic code \( C \subseteq R_{n,\lambda} \) there is exactly one \( \mu_q \)-invariant subset \( P \subseteq P_{n,\lambda} \) such that, for any \( a(X) \in R_{n,\lambda} \),

- \( a(X) \in C \) if and only if \( a(X)f_P(X) \equiv 0 \pmod{X^n - \lambda} \);
- \( a(X) \in C \) if and only if \( f_{\overline{P}}(X) \mid a(X) \).

The polynomial \( f_P(X) \) is said to be a *check polynomial* of the \( \lambda \)-constacyclic code \( C \), while the polynomial \( f_{\overline{P}}(X) \) is said to be a *generating polynomial* of \( C \). At that case we denote \( C = C_P \) and call it the \( \lambda \)-constacyclic code with check set \( P \) and defining set \( \overline{P} \) (which is corresponding to the zeros of \( C_P \)). It is easy to see that

\[
C_P \subseteq C_{P'}, \iff P \subseteq P', \text{ for } \mu_q \text{-invariant subsets } P, P' \subseteq P_{n,\lambda}; \tag{2.7}
\]

which implies that

- mapping a \( \lambda \)-constacyclic code of length \( n \) over \( F_q \) to its check set is an isomorphism from the lattice of \( \lambda \)-constacyclic codes of length \( n \) over \( F_q \) onto the lattice of \( \mu_q \)-invariant subsets of \( P_{n,\lambda} \).

Any element of \( R_{n,\lambda} \) has a unique representative: \( a(X) = a_0 + a_1X + \cdots + a_{n-1}X^{n-1} \). We always associate any word \( a = (a_0, a_1, \cdots, a_{n-1}) \in F_q^n \) with the element \( a(X) = a_0 + a_1X + \cdots + a_{n-1}X^{n-1} \in R_{n,\lambda} \), and vice versa.

For any \( a(X), b(X) \in R_{n,\lambda} \) associated to words \( a = (a_0, a_1, \cdots, a_{n-1}), b = (b_0, b_1, \cdots, b_{n-1}) \in F_q^n \), the Hamming weight \( w(a(X)) \) is defined by the Hamming weight of the word \( a \); the Euclidean inner product of \( a(X) \) and \( b(X) \) is defined by the Euclidean inner product of the words \( a \) and \( b \):

\[
\langle a(X), b(X) \rangle = \langle a, b \rangle = \sum_{i=0}^{n-1} a_i b_i. \tag{2.8}
\]
For $C \subseteq F_q^n$, denote
\[
C^\perp = \{ a \in F_q^n \mid \langle c, a \rangle = 0, \forall c \in C \},
\]
which is called the dual code of $C$. It is known that, for a $\lambda$-constacyclic code $C$, the dual code $C^\perp$ is no longer a $\lambda$-constacyclic code in general, see [4, 9], or see Lemma 3.5 below for more precise description.

**Remark 2.2.** We need the following group-theoretical results (cf. [7, Lemmas 3.1-3.3]). For fundamentals about groups, please refer to [1].

(i) Assume that $\sigma$ is a permutation of a finite set $\Gamma$. The group generated by $\sigma$ is denoted by $\langle \sigma \rangle$. The orbits of $\langle \sigma \rangle$ on $\Gamma$ is abbreviated by $\sigma$-orbits. The length of the $\sigma$-orbit containing $k \in \Gamma$ is equal to the index $|\langle \sigma \rangle : \langle \sigma \rangle_k|$, where $\langle \sigma \rangle_k$ denotes the subgroup consisting of the elements of $\langle \sigma \rangle$ which fix $k$. In particular, the length of any $\sigma$-orbit is a divisor of the order $\text{ord}(\sigma)$ of $\sigma$.

(ii) There is a partition $\Gamma = \Gamma_1 \cup \Gamma_2$ such that $\sigma(\Gamma_1) = \Gamma_2$ and $\sigma(\Gamma_2) = \Gamma_1$ if and only if the length of every $\sigma$-orbit on $\Gamma$ is even.

(iii) Further assume that $\sigma'$ is a permutation of a finite set $\Gamma'$, hence $(\sigma, \sigma')$ is a permutation of the product $\Gamma \times \Gamma'$. Then the order of the permutation $(\sigma, \sigma')$ is equal to the least common multiple of the order of $\sigma$ and the order of $\sigma'$; the length of the $(\sigma, \sigma')$-orbit containing $(k, k') \in \Gamma \times \Gamma'$ is equal to the least common multiple of the length of the $\sigma$-orbit containing $k \in \Gamma$ and the length of the $\sigma'$-orbit containing $k' \in \Gamma'$.

(iv) Assume that a finite group $G$ acts on a finite set $\Gamma$ and $N$ is a normal subgroup of $G$. Let $\Gamma/N$ be the set of $N$-orbits on $\Gamma$, called the quotient set of $\Gamma$ by $N$. Then the quotient group $G/N$ acts on the quotient set $\Gamma/N$. In particular, for $\sigma \in G$, the length of any $\sigma$-orbit on the quotient set $\Gamma/N$ is a divisor of the order of $\sigma$ in the quotient group $G/N$.

### 3 Three kinds of duadic constacyclic codes

Keep notations introduced in Section 2. In this section we define three kinds of duadic constacyclic codes and study their properties. We begin with a class of isometries between constacyclic codes, which is a generalization of the multipliers for cyclic codes (cf. [13, §4.3, eq.(4.4)]).

**Lemma 3.1.** Let $t, \bar{t}$ be integers coprime to $nr$ such that $t\bar{t} = 1 \pmod{nr}$. Then the following map (where $R_{n,\lambda} = F_q[X]/(X^n - \lambda^t)$, cf. Eqn (2.1))
\[
\varphi_t : R_{n,\lambda} \to R_{n,\lambda}, \quad \sum_{i=0}^{n-1} a_i X^i \mapsto \sum_{i=0}^{n-1} a_i X^{\bar{t}i} \pmod{X^n - \lambda^t},
\]
is an algebra isomorphism and preserves the Hamming weights of words, i.e., $w(\varphi_t(a(X))) = w(a(X))$ for any $a(X) \in R_{n,\lambda}$. 

5
In the algebra \( R \), \( \psi_i \) is an algebra homomorphism. Hence it induces an algebra homomorphism:

\[
\hat{\psi}_i : F_q[[X]] \rightarrow F_q[[X]]/\langle X^n - \lambda^i \rangle, \\
\sum_i a_i X^i \mapsto \sum_i a_i X^{\tilde{i}_i} \pmod{X^n - \lambda^i}.
\]

In the algebra \( R_{n,\lambda^i} = F_q[X]/\langle X^n - \lambda^i \rangle \) we have the following computation:

\[
\hat{\psi}_i (X^n - \lambda) = X^{\tilde{t}_i} - \lambda = (\lambda^t)^{\tilde{t}_i} - \lambda = 0 \pmod{X^n - \lambda^i}.
\]

The algebra homomorphism \( \hat{\psi}_i \) induces an algebra homomorphism as follows.

\[
\varphi_i : F_q[X]/\langle X^n - \lambda \rangle \rightarrow F_q[X]/\langle X^n - \lambda^i \rangle, \\
\sum_{i=0}^{n-1} a_i X^i \mapsto \sum_{i=0}^{n-1} a_i X^{\tilde{i}_i} \pmod{X^n - \lambda^i}.
\]

For any \( i \) with \( 0 \leq i < n \), there are a unique \( t_i \) with \( 0 \leq t_i < n \) and a unique \( q_i \) such that \( \tilde{i}_i = nq_i + t_i \). Thus, in \( R_{n,\lambda^i} \) we have

\[
\varphi_i \left( \sum_{i=0}^{n-1} a_i X^i \right) = \sum_{i=0}^{n-1} a_i X^{\tilde{i}_i} = \sum_{i=0}^{n-1} a_i \lambda^{q_i} X^{t_i}.
\]  \hspace{1cm} (3.1)

Since \( i \mapsto t_i \) is a permutation of the index set \( \{0, 1, \ldots, n-1\} \) and all \( \lambda^{q_i} \neq 0 \), the homomorphism \( \varphi_i \) is bijective. Finally, it is obvious that \( w(\varphi_i(a(X))) = w(a(X)) \) for any \( a(X) \in R_{n,\lambda^i} \).

With notations in Eqn (3.1), let \( M_t \) be the monomial matrix which is the product of the diagonal matrix with diagonal elements \( \lambda^{t_i} \) for \( i = 0, 1, \ldots, n-1 \) and the permutation matrix \( i \mapsto t_i \) for \( i = 0, 1, \ldots, n-1 \). Eqn (3.1) implies:

- when \( \sum_{i=0}^{n-1} a_i X^i \) is viewed as the word \( (a_0, a_1, \ldots, a_{n-1}) \), the map \( \varphi_i \) is corresponding to the monomial transformation on \( F_q^n \) by multiplying \( M_t \).

Thus we call \( \varphi_i \) an isometry from \( R_{n,\lambda^i} \) to \( R_{n,\lambda^i} \).

Note that more general isometries were introduced in [8], but Lemma 3.1 contains more precise information for our later citations.

Next, we refine the set \( P_{n,\lambda^i} \) in Eqn (2.3) and the group \( G_{n,\lambda^i} \) in Eqn (2.4) for any \( t \in Z^*_n \). The decomposition \( n = n_r n'_r \) introduced in the following remark will be used throughout the paper.

**Remark 3.2.** Let \( n'_r \) be the maximal divisor of the integer \( n \) which is coprime to \( r \). Hence \( n = n_r n'_r \) such that \( n'_r \) is coprime to \( r \), and \( p|r \) for any prime divisor
Let $t \in \mathbb{Z}_{nr}^*$ as before. By Chinese Remainder Theorem (cf. \[7\] eq.(4.3), eq.(4.4)] for details),
\[
P_{n,\lambda'} = t + r\mathbb{Z}_{nr} \quad \text{CRT} \quad (t + r\mathbb{Z}_{nr,r}) \times \mathbb{Z}_{n'}_{t},
\]
\[
G_{n,r} = \mathbb{Z}_{n,r}^* \cap (1 + r\mathbb{Z}_{nr,r}) \quad \text{CRT} \quad (1 + r\mathbb{Z}_{nr,r}) \times \mathbb{Z}_{n'}_{t},
\]
(3.2)
where $\equiv$ stands for the equivalence by Chinese Remainder Theorem, and $1 + r\mathbb{Z}_{nr,r}$ is a subgroup of $\mathbb{Z}_{n,r}^*$ with order $|1 + r\mathbb{Z}_{nr,r}| = n_r$ (see Lemma 4.3 below for more details). The group $G_{n,r}$ acts on $P_{n,\lambda'}$ with $1 + r\mathbb{Z}_{nr,r}$ and $\mathbb{Z}_{n'}_{t}$ respectively acting on $t + r\mathbb{Z}_{nr,r}$ and $\mathbb{Z}_{n'}_{t}$ respectively.

There is a distinguished subset $P_{n,\lambda'}^{(0)}$ of $P_{n,\lambda'}$ as follows:
\[
P_{n,\lambda'}^{(0)} = (t + r\mathbb{Z}_{nr,r}) \times \{0\} \subseteq (t + r\mathbb{Z}_{nr,r}) \times \mathbb{Z}_{n'}_{t};
\]
(3.3)
that is, $P_{n,\lambda'}^{(0)}$ consists of the elements of $P_{n,\lambda'}$ which are divided by $n'_{t}$. It is easy to see that $P_{n,\lambda'}^{(0)}$ is $m_s$-invariant for any $s \in G_{n,r}$. In particular, $P_{n,\lambda'}^{(0)}$ is a union of some $g$-orbits. Let $\bar{n}'_{t}$ be an integer such that $n'_{t} \bar{n}'_{t} \equiv 1 \pmod{r}$. For $i \in P_{n,\lambda'}^{(0)}$, we can write $i = i' n'_{t}$; since $i' n'_{t} \equiv t \pmod{r}$, we see that $i' \equiv t \bar{n}'_{t} \pmod{r}$. Thus
\[
\prod_{i \in P_{n,\lambda'}^{(0)}} (X - \theta^i) = X^{n_r} - \lambda t \bar{n}'_{t}.
\]

Generalizing the notations for negacyclic codes in \[4\], we make the following definition for general constacyclic codes.

**Definition 3.3.** Let $t \in \mathbb{Z}_{nr}^*$ and $s \in G_{n,r}$ (then $\varphi_s$ is an isometry of $R_{n,\lambda'}$ to itself). By $C_{n,\lambda'}^{(0)} = C_{n,\lambda'}^{(0)}$ we denote the $\lambda'$-constacyclic code with check set $P_{n,\lambda'}^{(0)}$, i.e., $X^{n_r} - \lambda t \bar{n}'_{t}$ is a check polynomial of $C_{n,\lambda'}^{(0)}$, where $\bar{n}'_{t}$ is an integer such that $n'_{t} \bar{n}'_{t} \equiv 1 \pmod{r}$. Let $C \leq R_{n,\lambda'}$.

(i) If $R_{n,\lambda'} = C \oplus \varphi_s(C)$, i.e., $R_{n,\lambda'} = C + \varphi_s(C)$ and $C \cap \varphi_s(C) = 0$, then we say that $C$ and $\varphi_s(C)$ are a pair of **Type-I duadic $\lambda'$-constacyclic codes**.

(ii) If $R_{n,\lambda'} = C_{n,\lambda'}^{(0)} \oplus C \oplus \varphi_s(C)$, then we say that $C$ and $\varphi_s(C)$ are a pair of **even-like (or Type-II) duadic $\lambda'$-constacyclic codes**.

(iii) If $R_{n,\lambda'} = C + \varphi_s(C)$ and $C \cap \varphi_s(C) = C_{n,\lambda'}^{(0)}$, then we say that $C$ and $\varphi_s(C)$ are a pair of **odd-like duadic $\lambda'$-constacyclic codes**.

Note that, if $C$ and $\varphi_s(C)$ are a pair of even-like duadic $\lambda'$-constacyclic codes, i.e., $R_{n,\lambda'} = C_{n,\lambda'}^{(0)} + C + \varphi_s(C)$, $C \cap \varphi_s(C) = 0$ and $C_{n,\lambda'}^{(0)} \cap (C + \varphi_s(C)) = 0$, then it is easy to check that $\varphi_s^2(C) = C$. It is the same for Type-I duadic $\lambda'$-constacyclic codes and odd-like duadic $\lambda'$-constacyclic codes.
The following lemma shows that the isometry \( \varphi_t : R_{n, \lambda} \to R_{n, \lambda'} \) corresponding to the bijection \( \mu_t : P_{n, \lambda} \to P_{n, \lambda'} \).

**Lemma 3.4.** Let \( t \in \mathbb{Z}_{nr}^* \). If \( C_P \subseteq R_{n, \lambda} \) is a \( \lambda \)-constacyclic code with check set \( P \subseteq P_{n, \lambda} \), then

\[
\varphi_t(C_P) = C_{tP} \subseteq R_{n, \lambda'};
\]
i.e., \( f_{tP}(X) = \prod_{Q \in tP/\mu_q} f_Q(X) \) is a check polynomial of the \( \lambda' \)-constacyclic code \( \varphi_t(C_P) \).

**Proof.** Let \( c(X) \in C_P \). Then \( c(\theta^i) = 0 \) for all \( i \in P_{n, \lambda}\setminus P \), see Remark 2.1. By the definition of \( \varphi_t \) in Lemma 3.1, \( \varphi_t(c(X)) = c(X^t) + b(X)(X^n - \lambda^t) \) for some \( b(X) \in F_q[[X]] \), where \( t, \bar{t} \in \mathbb{Z}_{nr} \) satisfying that \( t\bar{t} = 1 \) (mod \( nr \)). Hence

\[
\varphi_t(c(\theta^i)) = c(\theta^{ti}) + b(\theta^i)(\theta^n - \lambda^t) = 0, \quad \forall \ i \in P_{n, \lambda}\setminus tP.
\]

So \( \varphi_t(c(X)) \in C_{tP} \), see Remark 2.1. Since \( \varphi_t \) is an algebra isomorphism,

\[
\dim(\varphi_t(C_P)) = \dim(C_P) = |P| = |tP| = \dim(C_{tP}).
\]

Thus \( \varphi_t(C_P) = C_{tP} \).

Modifying [5, Th.4], we have the following result.

**Lemma 3.5.** Let \( C \subseteq R_{n, \lambda} \) be a \( \lambda \)-constacyclic code. Set

\[
\text{Ann}(C) = \{ a(X) \in R_{n, \lambda} \mid a(X)c(X) = 0 \text{ in } R_{n, \lambda}, \forall c(X) \in C \},
\]

which is also a \( \lambda \)-constacyclic code. Then

\[
C^\perp = \varphi_{-1}(\text{Ann}(C)) \subseteq R_{n, \lambda^{-1}}.
\]

**Proof.** Let \( a(X) = \sum_{i=0}^{n-1} a_i X^i \in \text{Ann}(C) \). In \( R_{n, \lambda} \), since \( XX^{n-1} = \lambda \) is invertible, \( X \) is invertible. For \( c(X) \in C \), there is a \( b(X) = \sum_{i=0}^{n-1} b_i X^i \in C \) such that \( Xb(X) = c(X) \). In \( R_{n, \lambda} \), since \( c(X)a(X) = 0 \), \( b(X)a(X) = 0 \). Considering the coefficient of \( X^{n-1} \), we get

\[
b_0a_{n-1} + b_1a_{n-2} + \cdots + b_{n-1}a_0 = 0.
\]

In \( R_{n, \lambda^{-1}} \), since \( \lambda^{-1} = X^n \),

\[
\lambda^{-1} \varphi_{-1}(a(X)) = \lambda^{-1}a_0 + a_{n-1}X + \cdots + a_1X^{n-1}.
\]

Noting that, in \( R_{n, \lambda} \), \( Xb(X) \) is corresponding to the word \( (\lambda b_{n-1}, b_0, \cdots, b_{n-2}) \), we obtain that

\[
\lambda^{-1} \langle c(X), \varphi_{-1}(a(X)) \rangle = \langle Xb(X), \lambda^{-1} \varphi_{-1}(a(X)) \rangle = 0.
\]

In conclusion, \( \varphi_{-1}(a(X)) \in C^\perp \). Thus \( \varphi_{-1}(\text{Ann}(C)) \subseteq C^\perp \). Since \( \dim C^\perp = n - \dim C = \dim \text{Ann}(C) \), we get \( C^\perp = \varphi_{-1}(\text{Ann}(C)) \).

\( \square \)
Since $R_{n,\lambda}$ is a semisimple algebra (i.e. $X^n - \lambda$ has no multiple roots), for any $\mu_q$-invariant subset $P \subseteq P_{n,\lambda}$, it is easy (cf. Eqn (2.6)) to see that
\[ \text{Ann}(C_P) = C_{\overline{P}}, \quad \text{where} \quad \overline{P} = P_{n,\lambda} \setminus P. \] (3.4)
Combining it with Lemma 3.5 and Lemma 3.4 we have an immediate corollary.

**Corollary 3.6.** With notations in Eqn (3.4), $C_P^\perp = C_{\overline{P}} = C_{\overline{\overline{P}}}$, where $-P = (-1)P$ and $\overline{-P} = P_{n,\lambda - 1} \setminus (-P)$.

**Theorem 3.7.** Let $C \leq R_{n,\lambda}$ and $s \in G_{n,r}$. Then $C$ and $\varphi_s(C)$ are a pair of even-like duadic $\lambda$-constacyclic codes if and only if $C^\perp$ and $\varphi_s(C)^\perp$ are a pair of odd-like duadic $\lambda^{-1}$-constacyclic codes.

**Proof.** Let $C = C_P$ with check set $P \subseteq P_{n,\lambda}$. Then $\varphi_s(C) = C_{sP}$ with check set $sP \subseteq P_{n,\lambda}$. Assume that $C$ and $\varphi_s(C)$ are even-like duadic $\lambda$-constacyclic codes, i.e., $R_{n,\lambda} = C_{n,\lambda}^{(0)} + C_P + C_{sP}$, $C_{n,\lambda}^{(0)} \cap (C_P + C_{sP}) = 0$ and $C_P \cap C_{sP} = 0$. By Eqn (2.7), $P_{n,\lambda} = P_{n,\lambda}^{(0)} \cup P \cup sP$ and $P_{n,\lambda}^{(0)}$, $P$, $sP$ are disjoint each other. Note that $\mu_{-1}$ transforms $P_{n,\lambda}$ to $P_{n,\lambda - 1}$ bijectively and $-P_{n,\lambda}^{(0)} = P_{n,\lambda - 1}^{(0)}$ obviously. We get that $P_{n,\lambda - 1} = P_{n,\lambda - 1}^{(0)} \cup (-P) \cup (-sP)$ and $P_{n,\lambda - 1}^{(0)}$, $-P$, $-sP$ are disjoint each other. So
\[ \overline{-P} = P_{n,\lambda - 1} \setminus (-P) = P_{n,\lambda - 1}^{(0)} \cup (-sP), \]
\[ \overline{-sP} = P_{n,\lambda - 1} \setminus (-sP) = P_{n,\lambda - 1}^{(0)} \cup (-P). \]
In $R_{n,\lambda - 1}$, by Corollary 3.6 we have $C_P^\perp = C_{\overline{P}}$ and $C_{sP}^\perp = C_{\overline{\overline{P}}}$. By Eqn (2.7), from the above equalities we obtain that
\[ R_{n,\lambda - 1} = C_P^\perp + C_{sP}^\perp, \quad C_P^\perp \cap C_{sP}^\perp = C_{P_{n,\lambda}^{(0)}} = C_{n,\lambda - 1}^{(0)}. \]
Thus, $C_P^\perp$ and $C_{sP}^\perp = \varphi_s(C_P)^\perp$ are odd-like duadic $\lambda^{-1}$-constacyclic codes.

Conversely, assume that $C_P^\perp$ and $C_{sP}^\perp$ are odd-like duadic $\lambda^{-1}$-constacyclic codes. It is easy to check that all the arguments in the above paragraph can be reversed. Thus we can backward step by step to reach the conclusion that $C_P$ and $\varphi_s(C_P)$ are even-like duadic $\lambda$-constacyclic codes. \qed

In the special case where $r = 1$ (i.e., cyclic codes are considered) and $s = -1$, the result [15, Th. 6.4.2] is a consequence of the above theorem.

**Lemma 3.8.** Let $t \in \mathbb{Z}_{n,r}$, and $C_P \leq R_{n,\lambda}$ be a $\lambda$-constacyclic code with check set $P \subseteq P_{n,\lambda}$. The following three are equivalent to each other.

(i) $\varphi_t(C_P) \leq C_P^\perp$ (at that case we call $C$ a $\varphi_t$-isometrically orthogonal code);
(ii) $\varphi_{-t}(C) \leq R_{n,\lambda}$ and $C_P \cap \varphi_{-t}(C_P) = 0$;
(iii) $-t \in G_{n,r}$ and $P \cap (-tP) = \emptyset$. 

9
Proof. (i) \(\Leftrightarrow\) (iii). By Lemma 3.4 and Corollary 3.1 (i) holds if and only if \(C_{tP} \subseteq C_{tP}\) where \(-P = P_{n,\lambda-1}\langle-P\rangle\); by Eqn (2.7), it is equivalent to that \(tP \subseteq -P\) where \(P = P_{n,\lambda}\langle P\rangle\); i.e., \(-tP \subseteq P\), (iii) holds.

(ii) \(\Leftrightarrow\) (iii). “\(\varphi_{-t}(C) \subseteq R_{n,\lambda}\)” is obviously equivalent to “\(-t \in G_{n,r}\)”.

Taking \(t = 1\) in Lemma 3.8, we get a known consequence:

**Corollary 3.9.** A \(\lambda\)-constacyclic code \(C_P \subseteq R_{n,\lambda}\) with check set \(P \subseteq P_{n,\lambda}\) is self-orthogonal if and only if \(\lambda = \pm 1\) and \(P \cap (-P) = \emptyset\).

Generalizing the self-orthogonality, we consider the iso-orthogonality.

**Definition 3.10.** Let \(C \subseteq R_{n,\lambda}\) be a \(\lambda\)-constacyclic code.

(i) If there is an \(s \in G_{n,r}\) such that \(C\) is \(\varphi_{-s}\)-isometrically orthogonal (i.e., Lemma 3.8(i) for \(t = -s\) holds), then we say that \(C\) is isometrically self-orthogonal, or iso-orthogonal for short.

(ii) If there is an \(s \in G_{n,r}\) such that both \(C\) and \(\varphi_{s}(C)\) are \(\varphi_{-s}\)-isometrically orthogonal (hence \(C \cap \varphi_{s}(C) = 0\), see Lemma 3.8(ii)) and \(\varphi_{s}^2(C) = C\), then we say that \(C, \varphi_{s}(C)\) are an iso-orthogonal pair of \(\lambda\)-constacyclic codes.

(iii) An iso-orthogonal pair \(C, \varphi_{s}(C)\) of \(\lambda\)-constacyclic codes is said to be maximal if for any iso-orthogonal pair \(C', \varphi_{s'}(C')\) of \(\lambda\)-constacyclic codes we have \(\dim C' \leq \dim C\).

If \(C_P, \varphi_s(C_P)\) are Type-I duadic \(\lambda\)-constacyclic codes, i.e., \(P_{n,\lambda} = P \cup (sP)\) and \(P \cap (sP) = \emptyset\), then \(C_P, \varphi_s(C_P)\) are of course a maximal iso-orthogonal pair of \(\lambda\)-constacyclic codes. In fact, at that case both \(C_P\) and \(\varphi_s(C_P)\) are iso-dual \(\lambda\)-constacyclic codes, see [5]. Otherwise, if the Type-I duadic constacyclic codes do not exist, then we show that any pair of even-like duadic constacyclic codes is a maximal iso-orthogonal pair of constacyclic codes provided it does exist.

**Lemma 3.11.** Type-I duadic \(\lambda\)-constacyclic codes of length \(n\) over \(F_q\) exist if and only if the order of the quotient group \((1 + rZ_{n,r})/\langle q\rangle Z_{n,r}^{\ast}\) is even, where \(\langle q\rangle Z_{n,r}^{\ast}\) denotes the subgroup of \(Z_{n,r}^{\ast}\) generated by \(q\).

Proof. Note that \(q \in 1 + rZ_{n,r}\), hence \(\langle q\rangle Z_{n,r}^{\ast} \subseteq 1 + rZ_{n,r}\). This lemma has been included in [7] Th.2.2 where more complicated results are proved. For convenience, we sketch a quick proof of the lemma. If \((1 + rZ_{n,r})/\langle q\rangle Z_{n,r}^{\ast}\) is of even order, we take \(s_0 \in 1 + rZ_{n,r}\) such that in the quotient group the element \(s_0\) has order 2; and take \(s \in G_{n,r}\) such that \(s \stackrel{\text{CRT}}{\equiv} (s_0, 1) \in (1 + rZ_{n,r}) \times Z_{n,r}^{\ast}\), cf. Eqn (3.2). By Remark 2.2(iii) and (iv), it is easy to see that any \(s\)-orbit on \(P_{n,\lambda}/\mu_q\) has length 2. By Remark 2.2(ii), there is a \(\mu_q\)-invariant subset \(P \subseteq P_{n,\lambda}\) such that \(P_{n,\lambda} = P \cup sP\) and \(P \cap sP = \emptyset\). Hence \(C_P\) and \(C_{sP}\) are a pair of Type-I duadic \(\lambda\)-constacyclic codes.
Conversely, if \( C_P \) and \( C_sP \) are a pair of Type-I duadic \( \lambda \)-constacyclic codes, by Remark 2.2(ii), the length of any \( s \)-orbit on \( P_{n,\lambda}^{(0)}/\mu_q \) is even; so in the quotient group \((1 + r\mathbb{Z}_{n,r})/\langle q \rangle \mathbb{Z}_{n,r}^*\), the order of the element \( s \) is even (cf. Remark 2.2(i)). Hence the order of the group \((1 + r\mathbb{Z}_{n,r})/\langle q \rangle \mathbb{Z}_{n,r}^*\) is even.

**Theorem 3.12.** Assume that Type-I duadic \( \lambda \)-constacyclic codes of length \( n \) do not exist but Type-II duadic \( \lambda \)-constacyclic codes of length \( n \) exist. Then any pair \( C_P, \varphi_s(C_P) \) of Type-II duadic \( \lambda \)-constacyclic codes of length \( n \) is a maximal iso-orthogonal pair of \( \lambda \)-constacyclic codes.

**Proof.** By Lemma 3.11 and the assumption of the theorem, the order of the quotient group \((1 + r\mathbb{Z}_{n,r})/\langle q \rangle \mathbb{Z}_{n,r}^*\) is odd. Then, by Remark 2.2(iv), for any \( s' \in G_{n,r} \), the length of any \( s' \)-orbit on the quotient set \( P_{n,\lambda}^{(0)}/\mu_q \) is odd.

Now we prove the theorem by contradiction. Suppose that \( C_{P'} \) and \( \varphi_{s'}(C_{P'}) \) are an iso-orthogonal pair of \( \lambda \)-constacyclic codes such that

\[
\dim C_{P'} > \dim C_P = |P| = \frac{n - n_r}{2}.
\]

Set \( P'' = P' \cap P_{n,\lambda}^{(0)} \subseteq P_{n,\lambda}^{(0)} \). Since \( s' P_{n,\lambda}^{(0)} = P_{n,\lambda}^{(0)} \), \( s' P'' = s' P' \cap P_{n,\lambda}^{(0)} \subseteq P_{n,\lambda}^{(0)} \).

Because \( P' \cap (s' P'') = \emptyset \) and

\[
|P' \cup (s' P')| = |P'| + |s' P'| = 2|P'| = 2 \dim C_{P'} > n - n_r = |P_{n,\lambda} \setminus P_{n,\lambda}^{(0)}|.
\]

Thus, \( P'' \) and \( s' P'' \) are non-empty subsets of \( P_{n,\lambda}^{(0)} \) such that \( P'' \cap s' P'' = \emptyset \) and \( s^2 P'' = P'' \). Note that both \( P'' \) and \( s' P'' \) are \( \mu_q \)-invariant. The permutation \( \mu_{s'} \) gives a bijection from the quotient set \( P''/\mu_q \) to the quotient set \( s' P''/\mu_q \).

Thus, the length of any \( s' \)-orbit on the quotient set \( (P'' \cup s' P'')/\mu_q \) is even. This is a contradiction. \( \square \)

## 4 Existence of Type-II duadic constacyclic codes

We keep notations introduced in Section 2, and describe the decomposition \( n = n_r n'_r \) in Remark 3.2 more precisely. Assume that \( r_1, \ldots, r_h, r'_1, \ldots, r'_h, p_1, \ldots, p_t \) are distinct primes such that

\[
\begin{align*}
 r &= r_1^{e_1} \cdots r_h^{e_h} r'_1^{e'_1} \cdots r'_h^{e'_h}, \\
 n &= r_1^{u_1} \cdots r_h^{u_h} p_1^{u_1} \cdots p_t^{u_t},
\end{align*}
\]

\( h, h' \geq 0; \) all \( e_i, e'_i \) are positive; \( \ell \geq 1, \) all \( u_i, v_i \) are positive.

Then \( n = n_r n'_r \) where

\[
\begin{align*}
n_r &= r_1^{u_1} \cdots r_h^{u_h}, \\
n'_r &= p_1^{v_1} \cdots p_t^{v_t}.
\end{align*}
\]

In this section we consider Eqn (3.2) and Eqn (3.3) only for \( t = 1 \), as restated below.

\[
\begin{align*}
P_{n,\lambda} &= 1 + r\mathbb{Z}_{n_r} \quad \text{CRT} \quad (1 + r\mathbb{Z}_{n_r}) \times \mathbb{Z}_{n'_r}, \\
G_{n,r} &= \mathbb{Z}_{n_r} \cap (1 + r\mathbb{Z}_{n_r}) \quad \text{CRT} \quad (1 + r\mathbb{Z}_{n_r}) \times \mathbb{Z}_{n'_r}.
\end{align*}
\]

11
\[ P_{n,\lambda}^{(0)} \overset{\text{CRT}}{=} (1 + rz_{n,r}) \times \{0\} \subseteq (1 + rz_{n,r}) \times \mathbb{Z}_{n'}^r. \]  

(4.4)

The main result of this section is as follows.

**Theorem 4.1.** Type-II duadic \( \lambda \)-constacyclic codes of length \( n \) over \( F_q \) exist if and only if one of the following two holds.

(i) \( n, r \) is even (equivalently, both \( n \) and \( r \) are even).

(ii) \( n \) is odd and \( q \) is a square of an element in \( \mathbb{Z}_{n'}^r \).

We will prove it in two cases. Case 1: \( n, r \) is even, see Theorem 4.4 below. Case 2: \( n, r \) is odd, see Theorem 4.6 below.

Correspondingly to Definition 3.3, we have the following definition.

**Definition 4.2.** Let notations be as in Eqn (4.3) and Eqn (4.4). Let \( P \subseteq P_{n,\lambda} \) and \( s \in G_{n,r} \).

(i) If \( P_{n,\lambda} = P \cup (sP) \) and \( P \cap (sP) = \emptyset \), then \( P, sP \) are called a Type-I duadic splitting of \( P_{n,\lambda} \) given by \( \mu_s \) (correspondingly, \( C_P, C_{sP} \) are a pair of Type-I duadic \( \lambda \)-constacyclic codes).

(ii) If \( P_{n,\lambda} = P(0)_{n,\lambda} \cup P \cup (sP) \) and \( P, P(0)_{n,\lambda}, sP \) are disjoint from each other, then \( P, sP \) are called a Type-II duadic splitting of \( P_{n,\lambda} \) given by \( \mu_s \) (correspondingly, \( C_P, C_{sP} \) are a pair of Type-II, or even-like, duadic \( \lambda \)-constacyclic codes).

Similarly to Definition 3.3, for the (i) and (ii) of the definition, it is easy to check that \( s^2P = P \).

We need more precise information on the subgroup \( 1 + rz_{n,r} \) of \( \mathbb{Z}_{n,r}^* \).

**Lemma 4.3.** With notations in Eqs (4.2)-(4.4), the following hold.

(i) \( 1 + rz_{n,r} \overset{\text{CRT}}{=} (1 + r^{e_1}z_{r_1+u_1}) \times \cdots \times (1 + r^{e_h}z_{r_h+u_h}) \), and the order of the direct factor \( |(1 + r^{e_i}z_{r_i+u_i})| = r^{u_i} \) for \( i = 1, \ldots, h \). Hence, the cardinality \( |1 + rz_{n,r}| = |P_{n,\lambda}^{(0)}| = n_r \).

(ii) The group \( 1 + rz_{n,r} \) has even order if and only if both \( n \) and \( r \) are even. If it is the case, assuming that \( r_1 = 2, e = e_1 \geq 1 \) and \( u = u_1 \geq 1 \), we have

\[ 1 + rz_{n,r} \overset{\text{CRT}}{=} (1 + 2^{e_1}z) \times (1 + 2^{e_2}z) \times \cdots \times (1 + 2^{e_h}z) \]

with \( 1 + 2^eZ_{2^{e+u}} \) being the Sylow 2-subgroup of \( 1 + rz_{n,r} \).

(iii) Type-I duadic splittings of \( P_{n,\lambda} \) exist if and only if both \( n \) and \( r \) are even and \( (q)Z_{2^{e+u}} \subseteq 1 + 2^eZ_{2^{e+u}} \), where \( (q)Z_{2^{e+u}} \) denotes the subgroup of \( Z_{2^{e+u}} \) generated by \( q \).
Proof. (i). With the notation in Eqn 4.1, by Chinese Remainder Theorem we have (cf. [2, eq.(4.3)] for more details):

\[ 1 + r\mathbb{Z}_{n,r} = (1 + r_1\mathbb{Z}_{e_1}^{r_1+u_1}) \times \cdots \times (1 + r_k\mathbb{Z}_{e_k}^{r_k+u_k}) \times (1 + r'_1\mathbb{Z}_{e'_1}^{r'_1}) \times \cdots \times (1 + r'_h\mathbb{Z}_{e'_h}^{r'_h}). \]

But \( 1 + r_i^{e_i}Z_{e'_i} = 1 \) for \( i = 1, \cdots, h', \) and \( |(1 + r_i^{e_i}Z_{e'_i}^{r'_i})| = r_i^{u_i} \) for \( i = 1, \cdots, h. \) So (i) holds.

(ii) follows from (i) obviously.

(iii). By Lemma 4.3, Type-I duadic splittings of \( P_{n,\lambda} \) exist if and only if \((1 + r\mathbb{Z}_{n,r})/\langle q \rangle Z_{2e+u}^r \) is a group of even order; by (ii), if and only if the quotient of the Sylow 2-subgroup \((1 + 2^eZ_{2e+u})/\langle q \rangle Z_{2e+u}^r \) is non-trivial; i.e., (iii) holds.

Theorem 4.4. If both \( n \) and \( r \) are even, then the Type-II duadic \( \lambda \)-constacyclic codes of length \( n \) over \( F_q \) exist.

Proof. Let notations be as in Eqns 4.2-4.4. Since both \( n \) and \( r \) are even, we can assume, as in Lemma 4.3(ii), that \( r_1 = 2, e = e_1 \geq 1 \) and \( u = u_1 \geq 1. \) If \( P, sP \) are a Type-I splitting of \( P_{n,\lambda} \) given by \( \mu_s \), then it is easy to check that \( P', sP' \) are a Type-II splitting of \( P_{n,\lambda} \) given by \( \mu_s \), where \( P' = P \setminus \langle P_{n,\lambda} \cap P \rangle. \) So we can further assume that Type-I duadic \( \lambda \)-constacyclic codes of length \( n \) do not exist. Hence, by Lemma 4.3(iii), \( q \) generates the multiplicative group \( 1 + 2^eZ_{2e+u}, i.e., \text{ord}_{Z_{2e+u}^r}(q) = 2^t. \)

To prove the existence of Type-II duadic \( \lambda \)-constacyclic codes of length \( n \), by Remark 2.2 (i), (ii) and (iv), it is enough to show that there is an integer \( s \in G_{n,r} \) such that \( \text{ord}_{Z_{n,r}^{e}}(s) = 2^f \) with \( f \geq 1 \) and

\[ sQ \neq Q, \quad \text{for any } q\text{-orbit } Q \text{ on } P_{n,\lambda}\setminus P_{n,\lambda}^{(0)}, \quad (4.5) \]

By Lemma 4.3(ii), we write \( 1 + r\mathbb{Z}_{n,r} = (1 + 2^eZ_{2e+u}) \times L \) with \( L \) being a group of odd order. By Eqn 4.2, we refine Eqn 4.3 as follows:

\[ P_{n,\lambda} \cong (1 + 2^eZ_{2e+u}) \times L \times Z_{p_1^{e_1}} \times \cdots \times Z_{p_\ell^{e_\ell}}, \]

\[ G_{n,r} \cong (1 + 2^eZ_{2e+u}) \times L \times Z_{p_1^{e_1}} \times \cdots \times Z_{p_\ell^{e_\ell}}. \]

Let \( 1 \leq i \leq \ell. \) Then \( p_i \) is an odd prime and \( Z_{p_i^{e_i}} \) is a cyclic group of order \( p_i^{e_i-1}(p_i - 1). \) Since \( p_i - 1 \) is coprime to \( p_i^{e_i-1}, \) there is a unique subgroup \( H_i \) of \( Z_{p_i^{e_i}} \) such that

\[ Z_{p_i^{e_i}} = (1 + p_iZ_{p_i^{e_i}}) \times H_i \quad (4.6) \]

and the natural homomorphism \( Z_{p_i^{e_i}} \rightarrow Z_{p_i^{e_i}} \) induces an isomorphism \( H_i 
\cong Z_{p_i^{e_i}}. \)

Note that \( 2 \mid (p_i - 1) = |Z_{p_i^{e_i}}|. \) We choose an integer \( s_i \in Z_{p_i^{e_i}} \) in two cases.
Case 1: If \( \text{ord}_{Z_{p_i}^{v_i}}(q) \) is odd, we take \( s_i \in H_i \) such that \( \text{ord}_{H_i}(s_i) = 2^{f_i} \) with \( f_i = 1 \).

Case 2: if \( \text{ord}_{Z_{p_i}^{v_i}}(q) \) is even, then there is an odd integer \( d_i \) such that the order \( \text{ord}_{Z_{p_i}^{v_i}}(q^{d_i}) = 2^{f_i} \) with \( f_i \geq 1 \) (hence \( q^{d_i} \in H_i \)) at that case, we take \( s_i = q^{d_i} \).

Let
\[
\begin{align*}
  s = (1, 1, s_1, \cdots, s_\ell) & \in (1 + 2^e \mathbb{Z}_{2^{e+u}}) \times L \times \mathbb{Z}_{p_1}^{v_1} \times \cdots \times \mathbb{Z}_{p_\ell}^{v_\ell}.
\end{align*}
\]

Then \( \text{ord}_{Z_{p_i}^{v_i}}(s) = 2^f \) where \( f = \max\{f_1, \cdots, f_\ell\} \geq 1 \).

Let \( Q \) be any \( q \)-orbit on \( P_{n, \lambda} \) outside \( P_{n, \lambda}^{(0)} \), as in Eqn (4.5). Take
\[
(\alpha, \alpha', \alpha_1, \cdots, \alpha_\ell) \in Q \quad \text{with} \quad \alpha \in 1 + 2^e \mathbb{Z}_{2^{e+u}}, \ \alpha' \in L, \ \alpha_i \in \mathbb{Z}_{p_i}^{v_i} \quad \text{for} \quad i = 1, \cdots, \ell.
\]

Since \( q \) generates \( 1 + 2^e \mathbb{Z}_{2^{e+u}} \), we have \( q' \alpha \equiv 1 \pmod{2^{e+u}} \) for some integer \( t \).

Set \( k' = q' \alpha' \) and \( k_i = q_i \alpha_i \in \mathbb{Z}_{p_i}^{v_i} \), for \( i = 1, \cdots, \ell \). Then
\[
(1, k', k_1, \cdots, k_\ell) = q'(\alpha, \alpha', \alpha_1, \cdots, \alpha_\ell) \in Q.
\]

Now we prove Eqn (4.5) by contradiction. Suppose that \( sQ = Q \). Because \( Q \cap P_{n, \lambda}^{(0)} = \emptyset \), there is an index \( m \) with \( 1 \leq m \leq \ell \) such that \( k_m \not\equiv 0 \pmod{p_m^{v_m}} \).

Since \( sQ = Q \),
\[
s(1, k', k_1, \cdots, k_m, \cdots, k_\ell) = (1, k', s_1 k_1, \cdots, s_m k_m, \cdots, s_\ell k_\ell) \in Q.
\]

Thus, there is an integer \( j \) such that
\[
q^j(1, k', k_1, \cdots, k_m, \cdots, k_\ell) = (1, k', s_1 k_1, \cdots, s_m k_m, \cdots, s_\ell k_\ell).
\]

In particular,
\[
q^j \equiv 1 \pmod{2^{e+u}} \quad \text{and} \quad q^j k_m \equiv s_m k_m \pmod{p_m^{v_m}}.
\]

Since \( \text{ord}_{Z_{p_i}^{v_i}}(q) = 2^e \), from the first equality we have \( j \equiv 0 \pmod{2^e} \), in particular, \( j \) is even. Next, write \( k_m = p_m^{v_m} k_m' \) with \( p_m \not| k_m' \), then \( 0 \leq v_m' < v_m \) because \( k_m \not\equiv 0 \pmod{p_m^{v_m}} \). The second equality becomes:
\[
q^j p_m^{v_m} k_m' \equiv s_m p_m^{v_m} k_m' \pmod{p_m^{v_m}}.
\]

Hence
\[
q^j \equiv s_m \pmod{p_m^{v_m - v_m'}}.
\]

Therefore, \( v_m - v_m' \geq 1 \), we get
\[
q^j \equiv s_m \pmod{p_m} \quad \text{(4.7)}.
\]

At Case 1, in the group \( Z_{p_m}^{*} \), the order of the element \( q^j \) is odd, but the order of \( s_m \) is 2; it is a contradiction to Eqn (4.7).
At Case 2, in the group $\mathbb{Z}_{p_m}^*$ the order of the element $q$ is even; but $j$ is even and $d_m$ is odd, hence
\[
\nu_2(\text{ord}_{\mathbb{Z}_{p_m}^*}(q^j)) < \nu_2(\text{ord}_{\mathbb{Z}_{p_m}^*}(q)) = \nu_2(\text{ord}_{\mathbb{Z}_{p_m}^*}(q^{d_m})),
\]
where $\nu_2(t)$ denotes the 2-adic valuation of the integer $t$, i.e., $2^{\nu_2(t)}$ is the maximal power of 2 dividing $t$. In particular, $q^j \not\equiv q^{d_m} \pmod{p_m}$, which contradicts to Eqn (4.7), as we have chosen $s_m = q^{d_m}$ at this case.

The contradictions finish the proof of the theorem. $\square$

Taking $r = 2$, from Theorem 4.4 we get the following immediate consequence which has been proved in [4].

**Corollary 4.5** ([4]). If $n$ is even, then Type-II duadic negacyclic codes of length $n$ over $F_q$ exist.

By $\nu_2(t)$ we denote the 2-adic valuation of the integer $t$ as before.

**Theorem 4.6.** Let $n = n_rn_r'$ and $n_r' = p_1^{\nu_1} \cdots p_\ell^{\nu_\ell}$ as in Eqn (4.2). Assume that $n_r$ is odd (equivalently, $n$ or $r$ is odd). Then the following three are equivalent to each other.

(i) Type-II duadic $\lambda$-constacyclic codes of length $n$ over $F_q$ exist.

(ii) For all $i = 1, \cdots, \ell$, $p_i$ is odd and $\nu_2(\text{ord}_{\mathbb{Z}_{p_i}^*}(q)) < \nu_2(p_i - 1)$ (i.e. $q$ does not generate the Slow $2$-subgroup of $\mathbb{Z}_{p_i}^*$).

(iii) $n_r'$ is odd and $q$ is a square of an element in $\mathbb{Z}_{n_r'}$.

**Proof.** (i)$\Rightarrow$(ii). By Lemma 4.3(i), $|1 + r\mathbb{Z}_{n_r}| = |F_{n,\lambda}^{(0)}| = n_r$. The existence of Type-II splittings of $P_{n,\lambda}$ implies that the cardinality $|P_{n,\lambda}\backslash F_{n,\lambda}^{(0)}| = n - n_r$ is even. By the assumption of the theorem, $n_r$ is odd. Thus $n$ is odd, hence $n_r'$ is odd. That is, $p_i$ for $i = 1, \cdots, \ell$ are all odd.

Suppose that for some $i$, say $i = 1$, $p_1$ is odd and $\nu_2(\text{ord}_{\mathbb{Z}_{p_1}^*}(q)) = \nu_2(p_1 - 1)$.

We assume that $S$ is the Slow $2$-subgroup of $\mathbb{Z}_{p_1}^*$, Thus $|S| = 2^{\nu_2(p_1 - 1)}$ and $q$ generates $S$, and $\mathbb{Z}_{p_1}^* = S' \times S$ for a subgroup $S'$ of odd order. Then
\[
(1 + r\mathbb{Z}_{n_r}) \times \mathbb{Z}_{p_1}^* = (1 + r\mathbb{Z}_{n_r}) \times S' \times S
\]
with $(1 + r\mathbb{Z}_{n_r}) \times S'$ being a direct factor of odd order. Thus, the quotient group
\[
((1 + r\mathbb{Z}_{n_r}) \times \mathbb{Z}_{p_1}^*)/\langle q \rangle (1 + r\mathbb{Z}_{n_r}) \times \mathbb{Z}_{p_1}^*
\]
is of odd order, where $\langle q \rangle (1 + r\mathbb{Z}_{n_r}) \times \mathbb{Z}_{p_1}^*$ is the subgroup of $(1 + r\mathbb{Z}_{n_r}) \times \mathbb{Z}_{p_1}^*$ generated by $q$. Take
\[
\alpha = (1, 1, 0, \cdots, 0) \in (1 + r\mathbb{Z}_{n_r}) \times \mathbb{Z}_{p_1}^{\nu_1} \times \mathbb{Z}_{p_2}^{\nu_2} \times \cdots \times \mathbb{Z}_{p_\ell}^{\nu_\ell}.
\]

15
Let \( Q_0 \) be the \( q \)-orbit containing \( \alpha \). Then \( \alpha \notin P_{n,\lambda}^{(0)} \) and \( Q_0 \subseteq P_{n,\lambda} \setminus P_{n,\lambda}' \). Let

\[
s \overset{\text{CRT}}{=} (s_0, s_1, s_2, \ldots, s_\ell) \in (1 + r\mathbb{Z}_{n,r}) \times \mathbb{Z}_{p_1}^* \times \cdots \times \mathbb{Z}_{p_\ell}^*.
\]

In the quotient group described by Eqn (4.3), \((s_0, s_1)\) is an element of odd order. By Remark 2.2(iv), the length of the \( s \)-orbit on \( P_{n,\lambda}/\mu_q \) containing \( Q_0 \) is odd. Hence, by Remark 2.2(ii), the Type-II splittings of \( P_{n,\lambda} \) given by \( \mu_\alpha \) for any \( s \in G_{n,r} \) do not exist. This is a contradiction to the statement (i). So the equality \( \nu_2(\text{ord}_{Z_{p_\lambda}}(q)) = \nu_2(p_1 - 1) \) has to be false.

(iii)\(\Rightarrow\)(i). Assume that (ii) holds. We refine Eqn (4.3) as follows:

\[
P_{n,\lambda} \overset{\text{CRT}}{=} (1 + r\mathbb{Z}_{n,r}) \times \mathbb{Z}_{p_1}^* \times \cdots \times \mathbb{Z}_{p_\ell}^*,
\]

\[
G_{n,r} \overset{\text{CRT}}{=} (1 + r\mathbb{Z}_{n,r}) \times \mathbb{Z}_{p_1}^* \times \cdots \times \mathbb{Z}_{p_\ell}^*.
\]

By Eqn (4.6), \( Z_{p_\lambda}^* = (1 + p_\lambda \mathbb{Z}_{p_\lambda}) \times H_\lambda \) and the natural map \( \mathbb{Z}_{p_\lambda} \to Z_{p_\lambda}^* \) induces an isomorphism \( H_\lambda \cong \mathbb{Z}_{p_\lambda}^* \). Noting that the order \( |1 + p_\lambda \mathbb{Z}_{p_\lambda}| = p_\lambda^{\nu_1 - 1} \) is odd and \( \nu_2(\text{ord}_{Z_{p_\lambda}}(q)) < \nu_2(p_1 - 1) \), we can find an integer \( s_i \) such that

\[
s_i \notin \langle q \rangle Z_{p_\lambda}^* \quad \text{but} \quad s_i^2 \equiv q \pmod{p_\lambda^{\nu_1}}, \quad i = 1, \ldots, \ell;
\]

where \( \langle q \rangle Z_{p_\lambda}^* \) stands for the subgroup of \( Z_{p_\lambda}^* \) generated by \( q \). Let

\[
s \overset{\text{CRT}}{=} (1, s_1, \ldots, s_\ell) \in (1 + r\mathbb{Z}_{n,r}) \times \mathbb{Z}_{p_1}^* \times \cdots \times \mathbb{Z}_{p_\ell}^*.
\]

Then, in the quotient group \( G_{n,r}/\langle q \rangle G_{n,r} \), the element \( s \) has order 2, where \( \langle q \rangle G_{n,r} \) stands for the subgroup of \( G_{n,r} \) generated by \( q \).

Let \( Q \) be any \( q \)-orbit on \( P_{n,\lambda} \) outside \( P_{n,\lambda}^{(0)} \). We prove by contradiction that \( sQ \neq Q \), which implies that the length of the \( \mu_\alpha \)-orbit on \( P_{n,\lambda}/\mu_q \) containing \( Q \) is even (see Remark 2.2(i) and (iv)), hence the statement (i) of the theorem holds, see Remark 2.2(ii).

Suppose that \( sQ = Q \). Take any \( k = (k_0, k_1, \ldots, k_\ell) \in Q \) with

\[
k_0 \in 1 + r\mathbb{Z}_{n,r}, \quad k_i \in \mathbb{Z}_{p_i}^* \quad \forall i = 1, \ldots, \ell.
\]

Then there is an integer \( d \) such that \( sk = q^d k \). Since \( Q \cap P_{n,\lambda}^{(0)} = \emptyset \), there is an \( m \) with \( 1 \leq m \leq \ell \) such that \( k_m \neq 0 \pmod{p_m^{v_m}} \). But \( sk_m \equiv q^d k_m \pmod{p_m^{v_m}} \). By the argument for Eqn (4.7), we have \( s \equiv q^d \pmod{p_m} \), which implies that \( s_m \in \langle q \rangle Z_{p_m}^* \). That is a contradiction to Eqn (4.9).

(ii)\(\Rightarrow\)(iii). Taking \( s' \in Z_{p_\lambda}^* \) such that \( s' \overset{\text{CRT}}{=} (s_1, \ldots, s_\ell) \in \mathbb{Z}_{p_1}^* \times \cdots \times \mathbb{Z}_{p_\ell}^* \) where \( s_i \) for \( i = 1, \ldots, \ell \) are taken in Eqn (4.9), we obtain \( s'^2 \equiv q \pmod{p_\lambda} \).

(iii)\(\Rightarrow\)(ii). Assume that \( s'^2 \equiv q \pmod{n_i} \). For \( p_i \) with \( i = 1, \ldots, \ell \), we have \( s'^2 \equiv q \pmod{p_i} \). If \( \text{ord}_{Z_{p_i}}(s') \) is odd, then \( \text{ord}_{Z_{p_i}}(q) \) is odd, hence \( \nu_2(\text{ord}_{Z_{p_i}}(q)) = 0 < \nu_2(p_1 - 1) \). Otherwise, \( \text{ord}_{Z_{p_i}}(s') \) is even, hence

\[
\nu_2(\text{ord}_{Z_{p_i}}(q)) = \nu_2(\text{ord}_{Z_{p_i}}(s'^2)) < \nu_2(\text{ord}_{Z_{p_i}}(s')) \leq \nu_2(p_1 - 1).
\]

\[\Box\]
At the extreme case where \( n_r = 1 \) (whatever \( r \) or not), \( n = n' \), and Eqn (4.3) becomes
eq c\text{yclic codes.}

We show that some good codes can be constructed from Type-II duadic constacyclic codes.

\[
P_{n,\lambda} \triangleq \{1\} \times \mathbb{Z}_n \cong \mathbb{Z}_n, \\
G_{n,r} \triangleq \{1\} \times \mathbb{Z}_n^* \cong \mathbb{Z}_n^*.
\]

Thus, we can view even-like duadic cyclic codes as a special case of Type-II duadic constacyclic codes.

**Corollary 4.7** ([15] Theorem 6.3.2). Type-II (even-like) duadic cyclic codes of length \( n \) over \( F_q \) exist if and only if \( n \) is odd and \( q \) is a square of an element in \( \mathbb{Z}_n \).

## 5 Examples

We show that some good codes can be constructed from Type-II duadic constacyclic codes.

Let \( F_{q'} \) be an extension of \( F_q \). Let \( \alpha = (\alpha_0, \alpha_1, \ldots, \alpha_{n-1}) \in F_q^n \) with coefficients different from each other, and \( \varepsilon = (\varepsilon_0, \varepsilon_1, \ldots, \varepsilon_{n-1}) \in F_q^n \) with coefficients all non-zero. The following \([n, k] \) linear code over \( F_{q'} \):

\[
\text{GRS}_k(\alpha; \varepsilon) = \\
\{ (\varepsilon_0 f(\alpha_0), \varepsilon_1 f(\alpha_1), \ldots, \varepsilon_{n-1} f(\alpha_{n-1})) \mid f(X) \in F_{q'}[X], \ \deg f(X) < k \}
\]
is called a generalized Reed-Solomon code, or GRS-code for short. And, the subfield subcode \( \text{GRS}_k(\alpha; \varepsilon)|_{F_q} \), which is the code over \( F_q \) by restricting the code \( \text{GRS}_k(\alpha; \varepsilon) \) over \( F_{q'} \) to the subfield \( F_q \), is said to be an \( \text{alternant code} \), cf. [17, Ch.9]. Obviously, \( \text{GRS}_k(\alpha; \varepsilon) \) is an \([n, k, n-k+1] \) MDS-code, and the minimum distance of its alternant code is at least \( n - k + 1 \).

**Proposition 5.1.** Assume that \( \nu_2(q-1) \geq 2 \) (equivalently, \( \nu_2(q+1) = 1 \)). Let \( n = q+1 = 2n' \), \( r = 2^{\nu_2(q-1)} \), \( r' = \frac{q+1}{2} \), and \( s = 1 + rr' \). Let

\[
P = \left\{ 1 + ri \mid \frac{n' + r'}{2} < i < \frac{3n' + r'}{2} \right\} \subseteq P_{n,\lambda} = 1 + r\mathbb{Z}_{nr}.
\]

Then \( P \) is \( \mu_q \)-invariant and \( C_P, \varphi_s(C_P) \) are a pair of even-like \( \lambda \)-constacyclic codes of length \( n \), which are alternant codes over \( F_q \) from GRS-codes over \( F_{q^2} \); in particular, they are \([q + 1, \frac{q+1}{2}, \frac{q+3}{2}] \) MDS-codes.

**Proof.** Denote \( c = \nu_2(q-1) \geq 2 \). Note that \( n_r = 2 \), \( n'_r = n' \) is odd and \( q = 1 + rr' = 1 + 2^c r' \) with \( r' \) being odd. So \( q \) generates the group \( 1 + r\mathbb{Z}_{nr} = 1 + 2^c \mathbb{Z}_{2^{c+1}} \). In particular, Type-I duadic \( \lambda \)-constacyclic codes of length \( n \) over \( F_q \) do not exist, cf. Lemma [4.3] (iii).

Since \( 0 < r' = \frac{q+1}{2} < \frac{q+3}{2} = n', \) we have

\[
r' < \frac{n' + r'}{2} < n' < \frac{n' + r'}{2} + n' = \frac{3n' + r'}{2} < n.
\]
And \(|P| = n' - 1\). Since \(\frac{n' + r'}{2} + 1 = \frac{2n' - 1}{2} + 1 = n'\),
\[
1 + r \frac{n' + r'}{2} = \frac{n'}{2} + \frac{r'}{2} + 1 = (\frac{n}{2} + 1)n'.
\]
And \(\frac{3n' + r'}{2} = n' + n'\). By Eqn (3.3),
\[
P(0) = \{1 + r \frac{n' + r'}{2}, 1 + r \frac{3n' + r'}{2}\}.
\]
For any \(1 + ri \in P_{n, \lambda}\), noting that \(q = 1 + rr' = n - 1\), we have
\[
q(1 + ri) = q + qri = 1 + rr' + nri - ri
\equiv 1 + r(r' - i) \equiv 1 + r(n + r' - i) \pmod{nr}.
\]
If \(\frac{n' + r'}{2} < i < \frac{3n' + r'}{2}\), it is easy to check that
\[
\frac{n' + r'}{2} < n + r' - i < \frac{3n' + r'}{2}.
\]
Thus, the subset \(P\) is \(\mu_q\)-invariant. Next we compute
\[
s(1 + ri) = (1 + rn')(1 + ri) = 1 + r(n' + i) + \frac{q}{r}nri
\equiv 1 + r(n' + i) \pmod{nr}.
\]
Since \(P\) consists of the points \(1 + ri\) with \(i\) running from \(\frac{n' + r'}{2} + 1\) to \(\frac{3n' + r'}{2} + n' - 1\) consecutively, we obtain that \(P \cap sP = \emptyset\). As \(|P_{n, \lambda}| = 2n' = |P(0)| + |P| + |sP|\), we further obtain that \(P = P(0) \cup P \cup sP\). In conclusion, \(C_P\) and \(\varphi_s(C_P)\) are a pair of even-like duadic \(\lambda\)-constacyclic codes over \(F_q\).

Because \(nr\) is a divisor of \((q + 1)(q - 1) = q^2 - 1\), in the extension \(F_{q^2}\) of \(F_q\), we can take a primitive \(nr\)-th root \(\theta\) of unity such that \(\theta'' = \lambda\). By \(\tilde{C}_P\), \(\varphi_s(\tilde{C}_P)\) we denote the pair of even-like duadic \(\lambda\)-constacyclic codes over \(F_{q^2}\). It is clear that \(C_P = \tilde{C}_P|_{\tilde{F}_q}\) is the subfield subcode from \(\tilde{C}_P\). It is the same for \(\varphi_s(C_P)\).

To complete the proof of the proposition, it is enough to show that
\[
\tilde{C}_P = GRS_{n'-1}(\alpha; \varepsilon),
\]
(5.1)
where \(\alpha = (1, \theta^{-r}, \ldots, \theta^{-r(n-1)})\) and \(\varepsilon = (1, \theta^{-(rz+1)}, \ldots, \theta^{-(rz+1)(n-1)})\) with \(z = \frac{n' + r'}{2} + 1\).

Any codeword of \(GRS_{n'-1}(\alpha; \varepsilon)\) in Eqn (5.1) is as follows:
\[
c_f = (f(1), \theta^{-(rz+1)}f(\theta^{-r}), \ldots, \theta^{-(rz+1)(n-1)}f(\theta^{-r(n-1)})),
\]
where \(f(X) = \sum_{k=0}^{n'-2} f_k X^k\) with \(f_k \in F_{q^2}\); it is corresponding to the following \(F_{q^2}\)-polynomial
\[
c_f(X) = \sum_{j=0}^{n-1} \theta^{-(rz+1)j}f(\theta^{-rj})X^j = \sum_{j=0}^{n-1} \theta^{-(rz+1)j} \sum_{k=0}^{n'-2} f_k \theta^{-rjk} X^j.
\]

18
Let \(1 + rm \in \overline{P} = P_{n,\lambda} \setminus P\), i.e., \(0 \leq m < z\) or \(z + n' - 1 \leq m < n\). Note that \(\theta^{-r}\) is a primitive \(n\)-th root of unity. For any \(i\) with \(z \leq i \leq z + n' - 2\), we have \(\theta^{-r(i-m)} \neq 1\). Then

\[
c_f(\theta^{1+rm}) = \sum_{j=0}^{n-1} \sum_{k=0}^{n'-2} \theta^{-r(\lambda z + 1)j} f_k \theta^{-rjk} \theta^{(1+rm)j} = \sum_{k=0}^{n'-2} \sum_{j=0}^{n-1} \theta^{-r(z+k-m)j} = \sum_{k=0}^{n'-2} f_k \cdot \frac{\theta^{-r(z+k-m)n} - 1}{\theta^{-r(z+k-m)} - 1} = 0.
\]

Since \(\overline{P}\) is the defining set of \(\tilde{C}_P\), we get that \(c_f(X) \in \tilde{C}_P\), see Remark 2.1. Thus

\[
\text{GRS}_{n'-1}(\alpha; \varepsilon) \subseteq \tilde{C}_P,
\]

which has to be an equality because the dimensions of the two hand sides are equal to each other. The expected Eqn (5.1) is proved.

The following is a specific numerical example of Proposition 5.1.

**Example 5.2.** Take \(q = 13\), \(n = 14\), \(r = 4\) (i.e., \(\lambda = 5\)). Then \(n_r = 2\), \(n' = n' = 7\), \(nr = 56\) and

\[
P_{n,\lambda} = \{1, 5, 9, 13, 17, 21, 25, 29, 33, 37, 41, 45, 49, 53\},
\]

which is partitioned into \(q\)-orbits as follows:

\[
Q_0 = P_{n,\lambda}^{(0)} = \{21, 49\},
Q_1 = \{1, 13\}, \quad Q_2 = \{5, 9\}, \quad Q_3 = \{17, 53\},
Q_4 = \{25, 45\}, \quad Q_5 = \{29, 41\}, \quad Q_6 = \{33, 37\};
\]

and \(\prod_{i \in P_{n,\lambda}^{(0)}} (X - \theta^i) = X^2 + 5\). Take \(s = 1 + r n' = 29\), then \(s^2 \equiv 1 \pmod{56}\). Then \(\mu_s\) permutes the quotient set \(P_{n,\lambda}/\mu_q\) of \(q\)-orbits into four orbits as follows:

\[
(Q_0)(Q_1, Q_5)(Q_2, Q_6)(Q_3, Q_4).
\]

Let

\[
P = Q_4 \cup Q_5 \cup Q_6 = \{25, 29, 33, 37, 41, 45\};
\]

then

\[
sP = Q_1 \cup Q_2 \cup Q_3 = \{1, 5, 9, 13, 17, 53\}.
\]

Obviously,

\[
P_{n,\lambda}^{(0)} \cup P \cup sP = P_{n,\lambda}, \quad P_{n,\lambda}^{(0)} \cap P = P_{n,\lambda}^{(0)} \cap sP = P \cap sP = \emptyset.
\]

Thus \(C_P, C_sP\) are a pair of even-like duadic \(\lambda\)-constacyclic codes over \(F_{13}\) with parameters \([14, 6, 9]\).
Finally we exhibit an example where $n_r$ is odd.

**Example 5.3.** Take $q = 4$, $n = 21$, $r = 3$ hence $F_4 = \{0, 1, \lambda, \lambda^2\}$. Then $n_r = 3$, $n_r' = 7$, $nr = 63$ and

$$P_{n,\lambda} = \{1, 4, 7, 10, 13, 16, 19, 22, 25, 28, 31, 34, 37, 40, 43, 46, 49, 52, 55, 58, 61\},$$

which is partitioned into $q$-orbits as follows:

- $Q_0 = P_{n,\lambda}^{(0)} = \{7, 28, 49\}$,
- $Q_1 = \{1, 4, 16\}$, $Q_2 = \{10, 40, 34\}$, $Q_3 = \{13, 52, 19\}$,
- $Q_4 = \{22, 25, 37\}$, $Q_5 = \{31, 61, 55\}$, $Q_6 = \{43, 46, 58\}$.

and

$$\prod_{i \in P_{n,\lambda}^{(0)}} (X - \theta^i) = X^{3} - \lambda.$$

Since $5^2 \equiv 4 \equiv q \pmod{7}$, even-like duadic $\lambda$-constacyclic codes exist. Take $s = 55 \equiv -8 \pmod{63}$, then $s^2 \equiv 1 \pmod{63}$. Then $\mu_s$ permutes the quotient set $P_{n,\lambda}/\mu_q$ of $q$-orbits into four orbits as follows:

$$(Q_0)(Q_1,Q_5)(Q_2,Q_6)(Q_3,Q_4).$$

Let

$$P = Q_1 \cup Q_2 \cup Q_3 = \{1, 4, 10, 13, 16, 19, 34, 40, 52\};$$

then

$$sP = Q_4 \cup Q_5 \cup Q_6 = \{22, 25, 31, 37, 43, 46, 55, 58, 61\}.$$

Obviously,

$$P_{n,\lambda}^{(0)} \cup P \cup sP = P_{n,\lambda}, \quad P_{n,\lambda}^{(0)} \cap P = P_{n,\lambda}^{(0)} \cap sP = P \cap sP = \emptyset.$$

Thus $C_P, C_{sP}$ are a pair of even-like duadic $\lambda$-constacyclic codes over $F_4$ with parameters $[21, 9, d]$, where the minimum distance $d \geq 8$ since the defining set of $C_{sP}$ is

$$P_{n,\lambda} \setminus sP = P_{n,\lambda}^{(0)} \cup P = \{1, 4, 7, 10, 13, 16, 19, 28, 34, 40, 49, 52\},$$

which contains 7 consecutive points 1, 4, 7, 10, 13, 16, 19 of $P_{n,\lambda}$.
