Subject headings halothane; sevoflurane; liver mitochondria; HPLC; hepatotoxicity

Abstract
AIM To study the pathogenesis of hepatotoxicity of halothane.
METHODS The effect of different concentration of halothane and sevoflurane on mitochondrial membrane phospholipids composition of rat liver were analyzed using high performance liquid chromatography (HPLC) technology.
RESULTS Halothane at low concentration could degrade mitochondrial membrane major phospholipids and increase lysophosphatidylcholine.
CONCLUSION The pathogenesis of halothane hepatotoxicity was the phospholipids variation on liver mitochondria.

INTRODUCTION
The effect of traditionally inhalational anesthetic halothane and new drug sevoflurane on mitochondrial membrane is reported below in an attempt to study the pathogenesis of halothane hepatotoxicity.

MATERIALS AND METHODS
Preparation of liver mitochondria and pretreatment of specimen
According to modified Estabook’s velocity gradient method, the mitochondria of male rat weighing 150g-200g was separated. Seventy mmol sucrose and 220mmol bovine serum albumin were used as isolation medium. Albumin was assayed by biuret reaction. The mitochondria concentration was adjusted to 10g/L-30g/L. Phospholipids except for ganglioside and acetal phospholipid were extracted using improved Higgins’ method. The mitochondrial suspension was mixed well with the extraction solvent (1:10, V/V), and stood for 15min. The albumin was removed by centrifugation. CaCl₂ 0.05mL/L was added to the supernatant, and stood for centrifugation (3000 r/min). The lower layer was evaporated to dryness under nitrogen at 40°C-50°C. After added with diluent accurately to the residue, the solution was sealed to protect from light and stored at -20°C for HPLC analysis. The whole procedure was carried out at 4°C in the air-tight ice-bath.

Preparation of solvent
The standard control phospholipids of phosphatidylethanolamine (PE), phosphatidylinositol (PI), phosphatidylserine (PS), phosphatidylcholine (PC), cardioliopin (CL), sphingomyelin (SPH) and lysophosphatidylcholine (LPC) were purchased from Sigma Co.

Extracting solution: chloroform:methanol:hydrochloric acid (2:1:0.01,V/V/V).

Moving phase: n-hexane:isopropanol:ethanol: potassium dihydrogen phosphate (25 mmol/L) : glacial acetic acid (370 : 485 : 100 : 562 : 0.1 V/V/V/V/V). The solution was evenly mixed and stood overnight for separating phosphoric acid crystal. After ultrafiltration and deoxygenation the supernatant was used as moving phase.

Standard solution: the standard control phospholipids were dissolved in the mixture of n-hexane: isopropanol (6:8, V/V). The concentration was 2g/L.
HPLC analytical method
ISUZU LC-6A liquid chromatograph, ISUZU Shim-Pack CLC-SIC column (6 mm × 15 cm), Guarc PAKTM prepared column were used. The detection was performed at 206nm. After reaction of low concentration and high concentration of halothane or sevoflurane with mitochondrial membrane phospholipids, 10ml reaction solution was taken out for repeated injection[3]. Each sample was repeated for 8 times, and linear velocity (mm/min) was recorded. Qualitative analysis was made by identification of the retention time with standard control samples. The eluting sequence referred to Patton sequence[4]. Quantitative analysis was made by calculating the peak area and the relative content of phospholipids was expressed by the ratio between peak area and albumin.

RESULTS
Qualitative analysis
By comparing the HPLC chromatograph peak of phospholipids affected by halothane at low and high concentration with that of the normal liver mitochondrial phospholipids, it could be seen that the main phospholipid peak decreased to some degree and LPC peak increased, especially when at high concentration. Sevoflurane at low concentration had no influence on phospholipid peak, but at high concentration it could decrease the main phospholipid peak and increase the LPC peak. However, the effect was not so obvious as that caused by halothane.

Quantitative analysis
The change of liver mitochondrial phospholipids caused by halothane and sevoflurane is shown in Table 1. Halothane at both high and low concentration could decrease the main liver mitochondrial phospholipids and increase LPC significantly. The change of phospholipids had no significant difference between sevoflurane at low concentration and the control while at high concentration the difference was marked. At high concentration, the change of phospholipids in liver mitochondria caused by halothane was much more obvious than that caused by sevoflurane.

Time-phase change
The effect on the liver mitochondrial phospholipid principle started and went up rapidly as soon as halothane contacted with mitochondria and reached the peak at 4h. At low concentration it could recover to the level of the control group at 6h-8h while at high concentration it could not even within 24h. In each phase there had no significant difference between low concentration of sevoflurane and the control. At high concentration the effect caused by sevoflurane reached the peak at 4h and recovered to the control level at 8 h - 12 h. The time-phase change on LPC by halothane and sevoflurane at high concentration is demonstrated in Figure 1.

| Group        | PE   | PI    | PS    | CL    | PC    | SPH   | LPC    |
|--------------|------|-------|-------|-------|-------|-------|--------|
| Control      | 1.48±0.26 | 1.16±0.19 | 0.84±0.09 | 1.02±0.11 | 2.93±0.28 | 3.98±0.59 | 4.54±0.42 |
| At low concentration Sevoflurane | 1.37±0.19 | 1.08±0.09 | 0.78±0.07 | 0.95±0.11 | 2.72±0.17 | 3.76±0.33 | 4.89±0.33 |
|              | (-7.62%) | (-7.12%) | (-6.93%) | (-6.55%) | (-7.19%) | (-5.52%) | (+7.81%) |
| Halothane    | 1.19±0.12 | 0.96±0.06 | 0.70±0.80 | 0.85±0.16 | 2.50±0.26 | 3.37±0.29 | 5.90±0.12 |
|              | (19.60%)a,b | (-17.24%)a,b | (-16.94%)a,b | (-16.25%)a,b | (-14.38%)a,b | (15.43%)a,b | (+30.1%)a,b |
| At high concentration Sevoflurane | 1.30±0.12c | 1.02±0.04a | 0.63±0.04a | 0.89±0.70a | 0.64±0.16a | 3.57±0.22a | 5.69±0.32a |

*P<0.05, **P<0.01 vs control; *P<0.05 vs sevoflurane.

Figure 1 The time phase change on LPC affected by halothane and sevoflurane in high concentration.
This study indicated that halothane at low concentration could degrade mitochondrial membrane major phospholipids and increase LPC, at high concentration it could damage mitochondrial membrane irreversibly. Although sevoflurane had action on mitochondria, the effect was reversible. Probably due to its molecular structure halothane soluble in liver mitochondria easily and destroy phospholipids obviously. Halothane had the similar result in the study on the inhalational anesthetic effect on liver mitochondria intimal fluidity[5].

Phospholipase A (PLA1, PLA2) is universal in liver membrane. Characterized by intramembranous mode of action, PLA2 has a high activity in mitochondria and the highest catalytic speed toward PE (twice that of PC, ten times of CL). PLA2 could be excited by Ca equilibration of liver cell caused by poison in vivo and in vitro. The phospholipid structure variation greatly influences biomembrane function and physical property including membrane conugase and receptor kinetics[6]. Some other studies showed that lipid variation such as mitochondrial phospholipids degradation and lipid peroxidation is an important original cause of liver cell damage. Destruction of the integration of mitochondria is the result of mutual function of the above-mentioned two mechanisms while degradation of membrane phospholipid caused by activation of mitochondria probably plays a more important role in the early damage of overall function of liver cells[7].

Besides hypoxia and low volume of blood flow the study also showed that mitochondrial phospholipids variation in the unorganized test is the main factor of halothane hepatotoxicity. Inhibition of PLA2 activity and antilipid peroxidation may be the important measure of antihalothane hepatotoxicity[8].
