Abstract

Background: Water dropwort (*Oenanthe javanica*) as a popular traditional medicine in Asia shows various biological properties including antioxidant activity. In this study, we firstly examined the neuroprotective effect of *Oenanthe javanica* extract (OJE) in the hippocampal cornus ammonis 1 region (CA1 region) of the gerbil subjected to transient cerebral ischemia.

Methods: Gerbils were established by the occlusion of common carotid arteries for 5 min. The neuroprotective effect of OJE was estimated by cresyl violet staining. In addition, 4 antioxidants (copper, zinc superoxide dismutase [SOD], manganese SOD, catalase, and glutathione peroxidase) immunoreactivities were investigated by immunohistochemistry.

Results: Pyramidal neurons in the CA1 region showed neuronal death at 5 days postischemia; at this point in time, all antioxidants immunoreactivities disappeared in CA1 pyramidal neurons and showed in many nonpyramidal cells. Treatment with 200 mg/kg, not 100 mg/kg, OJE protected CA1 pyramidal neurons from ischemic damage. In addition, 200 mg/kg OJE treatment increased or maintained antioxidants immunoreactivities. Especially, among the antioxidants, glutathione peroxidase immunoreactivity was effectively increased in the CA1 pyramidal neurons of the OJE-treated sham-operated and ischemia-operated groups.

Conclusion: Our present results indicate that treatment with OJE can protect neurons from transient ischemic damage and that the neuroprotective effect may be closely associated with increased or maintained intracellular antioxidant enzymes by OJE.

Key words: Antioxidant Enzymes; Hippocampal Cornus Ammonis 1 Region; Neuroprotection; *Oenanthe Javanica* Extract; Transient Cerebral Ischemia

Introduction

Cerebral ischemia leads to extensive and irreversible neuronal damage in various brain regions including hippocampus.¹⁻³ Even though the hippocampus, which is highly susceptible to ischemia, and pyramidal neurons in the hippocampal cornus ammonis 1 region (CA1 region) are most sensitive to ischemic damage.⁴ The neuronal loss of pyramidal neurons in the CA1 region commonly represents 3–4 days after initial ischemic insult and thus this unique process is termed “delayed neuronal death.”⁵⁻⁶ Mechanisms

of neuronal death following cerebral ischemia are awfully complex; there have been many theories regarding the mechanisms including glutamate excitotoxicity, oxidative stress, and inflammation.\textsuperscript{[7-9]} However, exact mechanism of ischemia-induced neuronal death has not been fully established yet.

Water dropwort (\textit{Oenanthe javanica} [\textit{O. javanica}]), a perennial member of the \textit{Oenanthe} genus in \textit{Apiaceae} family, is mainly cultivated in marshy areas of Asia and has been widely used in Korea as a very popular traditional medicine for the treatment of diseases including jaundice, hypertension, abdominal pain, fever, leucorrhoea, mumps, and urinary infections.\textsuperscript{[10]} Indeed, many researchers have shown that \textit{O. javanica} has various pharmacological and biological activities such as anti-inflammatory,\textsuperscript{[11]} antioxidant,\textsuperscript{[12]} and anti-hepatitis B virus activities.\textsuperscript{[13]} Furthermore, a recent study reported that persicarin isolated from \textit{O. javanica} displayed neuroprotective activity against glutamate-induced neurotoxicity in primary cultured rat cortical cells.\textsuperscript{[14]} However, no studies regarding effects of \textit{O. javanica} against cerebral ischemic damage have been reported yet.

Therefore, in this study, we examined the neuroprotective effect of \textit{O. javanica} extract (OJE) in the CA1 region of a gerbil model of 5 min transient cerebral ischemia and investigated the effect of OJE on ischemic CA1 region.

\section*{METHODS}

\subsection*{Experimental animals}

Six-month-old male Mongolian gerbils (\textit{Meriones unguiculatus}) were obtained from the Experimental Animal Center, Kangwon National University, Chuncheon, South Korea and housed according to the procedures for animal handling and care adhered to guidelines that are in compliance with the current international laws and policies (Guide for the Care and Use of Laboratory Animals, The National Academies Press, 8\textsuperscript{th} ed., 2011), and they were approved by the Institutional Animal Care and Use Committee at Kangwon University.

\subsection*{Preparation and treatment of \textit{Oenanthe javanica} extract}

\textit{O. javanica} were collected during 1-week in Kangwon Province (South Korea), in March 2013 and kept in a deep freezer (\textdegree{}C) for 2 days and 5 days after ischemia-reperfusion) and perfused transcardially with 4\% paraformaldehyde in 0.1 M phosphate-buffer (pH 7.4). The brain tissues were serially sectioned on a cryostat (Leica, Wetzlar, Germany) into 30-\mu m coronal sections. The sections were stained with 1\% CV acetate (Sigma, St. Louis, MO, USA) solution. After dehydration, the sections were mounted with Canada Balsam (Kanto, Tokyo, Japan).

\subsection*{Cresyl violet staining}

According to our previous method,\textsuperscript{[17]} cresyl violet (CV) staining was carried out. In brief, the vehicle-sham-, vehicle-ischemia-, OJE-sham-, and OJE-ischemia-groups (\textit{n} = 7 at each point in time) were anesthetized with sodium pentobarbital at the designated times (2 days and 5 days after ischemia-reperfusion) and perfused transcardially with 4\% paraformaldehyde in 0.1 M phosphate-buffer (pH 7.4). The brain tissues were serially sectioned on a cryostat (Leica, Wetzlar, Germany) into 30-\mu m coronal sections. The sections were stained with 1\% CV acetate (Sigma, St. Louis, MO, USA) solution. After dehydration, the sections were mounted with Canada Balsam (Kanto, Tokyo, Japan).

\subsection*{Immuno histochemistry for antioxidant enzymes}

Immuno histochemistry was done according to our previous method\textsuperscript{[19]} with sheep anti-copper, zinc superoxide dismutase (SOD1, 1:1000, Calbiochem, Darmstadt, Germany), sheep anti-manganese (SOD2, 1:1000, Calbiochem), rabbit anti-catalase (CAT, 1:800, Calbiochem), and mouse anti-glutathione peroxidase (Gpx, 1:800, Calbiochem). In brief, the sections were incubated with primary antibodies overnight at 4\degree{}C and exposed to biotinylated goat anti-sheep IgG, donkey anti-rabbit IgG, goat anti-mouse IgG, and streptavidin peroxidase complex (Vector, Burlingame, CA, USA). They were visualized with 3,3' -diaminobenzidine in 0.1 M Tris HCl buffer.

SOD1, SOD2, CAT, and Gpx immunoreactivity was measured from 8 sections per animal as follows. Images of SOD1-, SOD2-, CAT-, and Gpx-immunoreactive structures

\begin{tabular}{p{0.4\textwidth}}

In brief, the sections were incubated with primary antibodies overnight at 4\degree{}C and exposed to biotinylated goat anti-sheep IgG, donkey anti-rabbit IgG, goat anti-mouse IgG, and streptavidin peroxidase complex (Vector, Burlingame, CA, USA). They were visualized with 3,3' -diaminobenzidine in 0.1 M Tris HCl buffer.

SOD1, SOD2, CAT, and Gpx immunoreactivity was measured from 8 sections per animal as follows. Images of SOD1-, SOD2-, CAT-, and Gpx-immunoreactive structures
were taken from each layer through an AxioM1 light microscope (Carl Zeiss, Oberkochen, Germany) equipped with a digital camera (Axiocam, Carl Zeiss, Oberkochen, Germany) connected to a PC monitor (Samsung, Korea). Semi-quantification of their immunoreactivity was evaluated with digital image analysis software (MetaMorph 4.01; Universal Imaging Corporation, Downingtown, PA, USA). The mean immunoreactivity was measured by a 0–255 gray scale system (white to dark signal corresponded from 255 to 0). Based on this approach, the level of immunoreactivity was scaled as −, ±, +, ++ or +++ representing negative (gray scale value: ≥200), weakly positive (gray scale value: 150–199), moderate (gray scale value: 100–149), strong (gray scale value: 50–99), or very strong (gray scale value: ≤49), respectively.

Results

Cresyl violet-positive cells
CV-positive cells were well observed in all hippocampal subregions in the vehicle-sham-group [Figure 1A and 1a]. However, in the vehicle-ischemia-group, CV-positive pyramidal cells were hardly found in the stratum pyramidale of the CA1 region 5 days after ischemia-reperfusion [Figure 1B and 1b]. In the 100 mg/kg OJE-ischemia-group, the distribution pattern of CV-positive cells was similar to that in the vehicle-ischemia-group [Figure 1C and 1c]. However, in the 200 mg/kg OJE-ischemia-group, abundant CV-positive pyramidal cells were observed in the stratum pyramidale of the CA1 region 5 days after ischemia-reperfusion [Figure 1D and 1d].

Superoxide dismutase 1 and 2 immunoreactivity
In this study, change patterns of SOD1 and 2 were generally similar. Moderate SOD1 and 2 immunoreactivity was observed in the stratum pyramidale of the CA1 region of the vehicle-sham-group [Figure 2a and 2g]. In the vehicle-ischemia-groups, SOD1 and 2 immunoreactivity was not significantly changed in the stratum pyramidale at 2 days postischemia [Table 1 and Figure 2c and 2i]; however, at 5 days postischemia, SOD1 and 2 immunoreactivity was significantly decreased in the stratum pyramidale and found in many nonpyramidal cells [Table 1 and Figure 2e and 2k].

In the 200 mg/kg OJE-sham-group, SOD1 and 2 immunoreactivity in the stratum pyramidale was higher than that in the vehicle-sham-group [Table 1 and Figure 2b and 2h], and, in the 200 mg/kg OJE-ischemia-groups, the immunoreactivity in the stratum pyramidale was maintained until 5 days after ischemia-reperfusion [Table 1 and Figure 2d, 2f, 2j and 2l].

Catalases immunoreactivity
Strong CAT immunoreactivity was detected in the stratum pyramidale of the CA1 region of the vehicle-sham-group [Figure 3a]. In the vehicle-ischemia-groups, CAT immunoreactivity was slightly decreased in the stratum pyramidale at 2 days postischemia [Table 1 and Figure 3c]. At 5 days postischemia, CAT immunoreactivity in the stratum pyramidale was significantly decreased, and many nonpyramidal cells showed CAT immunoreactivity [Table 1 and Figure 3e].

Figure 1: Cresyl violet staining in the hippocampus of the vehicle-sham- (A and a), vehicle-ischemia- (B and b), 100 mg/kg Oenanthe javanica extract-ischemia- (C and c) and 200 mg/kg Oenanthe javanica extract-ischemia- (D and d) groups 5 days after postischemia. In the vehicle-ischemia-group, cresyl violet-positive pyramidal cells are hardly observed in the stratum pyramidale (black asterisk) of the hippocampal CA1 region. Abundant pyramidal cells (white asterisk) are stained with cresyl violet in the stratum pyramidale of the 200 mg/kg Oenanthe javanica extract-ischemia-group. CA: Cornus ammonis; DG: Dentate gyrus; SO: Stratum oriens; SR: Stratum radiatum. Scale bar = 400 μm (A, B, C and D) and 60 μm (a, b, c and d).

Figure 2: Superoxide dismutase 1 and 2 immunohistochemistry in the hippocampal cornus ammonis 1 region of the vehicle-sham- (a and g), vehicle-ischemia- (c, e, i and k), 200 mg/kg Oenanthe javanica extract-sham- (b and h), and 200 mg/kg Oenanthe javanica extract-ischemia- (d, f, j and l) groups. In the vehicle-ischemia-group, superoxide dismutase 1 and 2 immunoreactivity is significantly decreased in the stratum pyramidale 5 days postischemia. In the 200 mg/kg Oenanthe javanica extract-sham-group, superoxide dismutase 1 and 2 immunoreactivity in the stratum pyramidale (asterisks) is higher than that in the vehicle-sham-group, and the immunoreactivity is maintained. SOD: Superoxide dismutase; SO: Stratum oriens; SR: Stratum radiatum. Scale bar = 60 μm.
In the 200 mg/kg OJE-sham- and ischemia-groups, CAT immunoreactivity in the stratum pyramidale of the CA1 region was similar to that in the vehicle-sham-group [Table 1 and Figure 3b, 3d and 3f].

Glutathione peroxidase immunoreactivity

In the vehicle-sham-group, strong Gpx immunoreactivity was detected in the stratum pyramidale of the CA1 region [Figure 3g]. Gpx immunoreactivity was decreased in the vehicle-ischemia-groups and, 5 days after ischemia-reperfusion, Gpx immunoreactivity was dramatically decreased in the stratum pyramidale, and its immunoreactivity was shown in many nonpyramidal cells [Table 1 and Figure 3i and 3k].

**DISCUSSION**

Many studies have reported that traditional medicinal plant extracts show therapeutic effects against cerebral ischemic insults. However, the neuroprotective effect of OJE against cerebral ischemic insults has not been studied yet, even though *O. javanica* has multiple biological activities.

In this study, we firstly examined the neuroprotective effect of OJE against ischemia-induced neuronal damage, and found that OJE protected the pyramidal neurons of the CA1 region from cerebral ischemic damage. This result is related with a previous study that showed that persicarin isolated from *O. javanica* protected cultured rat cortical cells from glutamate-induced neurotoxicity.

To the best of our knowledge, this study is the first report that showed the neuroprotective effects of OJE in an animal model of cerebral ischemia.

It has been well accepted that cerebral ischemia induces oxidative stress caused by the excessive generation of reactive oxygen species (ROS) and that amassed ROS results in the adverse modification of cellular components such as DNA, protein and lipids, which can impair cellular function and cause neuronal death. To counteract oxidative stress, the intracellular antioxidant enzyme system, including SODs, CAT, and Gpx, converts ROS into less noxious compounds. Extensive experiments have shown that antioxidants have protective potential against ischemic damage.

In this study, to elucidate the neuroprotective mechanism of OJE against ischemia-induced neuronal damage, we examined changes in SODs, CAT, and Gpx in the ischemic CA1 region and found that SODs, CAT, and Gpx

---

**Table 1: Semi-quantification of immunoreactivities of antioxidant enzymes in the hippocampal CA1 region of the vehicle-ischemia- and OJE-ischemia-group**

| Antibodies | Group | Category | Time after ischemia/reperfusion |
|------------|-------|----------|---------------------------------|
|            |       |          | Sham | 2 days | 5 days |
| SOD1       | Vehicle| CSP      | ±    | ±      | ±      |
|            |        | CSOR     | ±    | ±      | ±      |
| OJE        | CSP    | ++       | ++   | ++     |
|            | CSOR   | ++       | +    | +      |
| SOD2       | Vehicle| CSP      | +    | +      | ±      |
|            |        | CSOR     | ±    | ±      | ±      |
| OJE        | CSP    | ++       | ++   | ++     |
|            | CSOR   | +        | +    | +      |
| CAT        | Vehicle| CSP      | ++   | ++     | ±      |
|            |        | CSOR     | ±    | ±      | ±      |
| OJE        | CSP    | ++       | ++   | ++     |
|            | CSOR   | ±        | ±    | ±      |
| Gpx        | Vehicle| CSP      | ++   | ++     | ±      |
|            |        | CSOR     | +    | +      |
| OJE        | CSP    | +++      | +++  | +++    |
|            | CSOR   | +        | +    | +      |

The levels of immunoreactivity were defined as five grades, negative (−), weakly positive (+), moderate (++), strong (+++) and very strong (+++). CSP: Cells in stratum pyramidale; CSOR: Cells in stratum oriens and radiatum; SOD: Superoxide dismutase; CAT: Catalase; Gpx: Glutathione peroxidase; OJE: *Oenanthe javanica* extract; CA1: Cornus ammonis 1.
immunoreactivities in the OJE-sham-group were significantly higher than those in the vehicle-sham-group. This finding is similar with our recent study that reported that treatment with OJE significantly increased expressions of intracellular antioxidant enzymes in the normal rat kidney.[31] In addition, we found that SODs, CAT, and Gpx immunoreactivities in the OJE-treated-groups were continuously maintained after ischemia-reperfusion, although their immunoreactivities in the vehicle-ischemia-group were significantly decreased 5 days after ischemia-reperfusion.

Recently, it was reported that OJE had protective effect against H2O2-induced oxidative damage through antioxidant activity in HePG2 cells.[32] In addition, we demonstrated that the maintenance or increase of intracellular antioxidant enzymes by the administration of some traditional medicinal plant extracts is closely associated with protective effects against ischemia-induced neuronal death in the gerbil hippocampal CA1 region.[17,33,34] Therefore, it could be postulated that higher and maintained expressions of intracellular antioxidant enzymes in ischemic neurons after treatment with some extracts may be related with neuroprotective effects against ischemic damage.

In brief, our results show, for the first time, that treatment with OJE protected CA1 pyramidal neurons from ischemic damage induced by transient cerebral ischemia and suggest that the neuroprotection of OJE is related with increased or maintained intracellular antioxidant enzymes by OJE.
