Abstract

We will prove that by averaging of random variables (r.v.) and random fields (r.f.) its tails of distributions do not increase in comparison with the tails of source variables, essentially or almost exact, under very weak conditions.

Key words and phrases. Random variables (r.v.) and random fields (r.f.), spatial and conditional averaging, probability, Lebesgue - Riesz, Yudovich, Grand Lebesgue norm and spaces, Euclidean space, martingales, uniform integrability, tail of distribution, measurable functions, Young - Fenchel (Legendre) transform, Young’s inequality, slowly varying function, natural function, normalized sums, filtration, generating function, upper and lower estimation, conditional expectation, rearrangement invariant (r.i.) space, examples, square variation.

1 Preliminary. Definitions. Notations.

Let \((\Omega = \{\omega\}, \mathcal{B}, \mathbb{P})\) be non-trivial probability space with expectation \(\mathbb{E}\) and Variation \(\text{Var}\) and let \((X = \{x\}, M, \mu)\) be another probability space: \(\mu(X) = 1\). Let also \(\xi = \xi(x) = \xi(x, \omega), x \in X, \omega \in \Omega\) be numerical valued separable bi-measurable random field.

There are at least two version to introduce the notion of an averaging in the probability theory.

A. Define
\[
\xi[X] \overset{def}{=} \int_X \xi(x) \mu(dx) -
\]

the spatial averaging.

B. **Conditional averaging.** Let \( F \) be some sigma-subalgebra of the source one \( B \). Define for arbitrary integrable numerical valued r.v. \( \eta \) the ordinary conditional expectation

\[
\eta\{F\} \overset{def}{=} \mathbb{E}\eta/F.
\]  

Our target in this preprint is to deduce the exact norm and tail of distribution estimations for both this averaging in the terms of tails and norms of the source datum.

We state as it is announced that by both the introduced averaging: of random variables (r.v.) and random fields (r.f.) its tails of distributions do not essentially exact increase in comparison with the tails of source variables, under very weak conditions.

Recall that the so-called *tail function* \( T_\tau(t) \) for the numerical valued r.v. \( \tau \) is defined as follows

\[
T_\tau(t) \overset{def}{=} \mathbb{P}(|\tau| \geq t), \ t \geq 0.
\]  

Correspondingly, the tail function for the numerical valued random field \( \zeta = \zeta(x) = \zeta(x, \omega) \) is understood in the uniform sense

\[
T_\zeta(t) \overset{def}{=} \sup_{x \in X} T_{\zeta(x)}(t), \ t \geq 0,
\]

is of course the last \( \sup \) is not trivial.

2 **Averaging of random fields.**

**Proposition 2.1.** Norm estimation.

Let \((G, \| \cdot \|_G)\) be arbitrary Banach functional space defined on the random variables (measurable functions) \( \zeta : \Omega \to \mathbb{R} \) such that

\[
\forall x \in X \Rightarrow \xi(x) \in G.
\]

Suppose also that the function \( \beta(x) := \| \xi(x) \|_G \), \( x \in X \) is measurable. Then by virtue of integral version of triangle inequality

\[
\| \xi[X] \|_G = \| \int_X \xi(x) \mu(dx) \|_G \leq
\]
\[
\int_X ||\xi(x)||G \, \mu(dx) = \int_X \beta(x) \, \mu(dx),
\]  
(4)

if of course the last integral is finite.

For instance, denote by \( L_p(\Omega, P) = L_p(\Omega) \), \( p \geq 1 \) the classical Lebesgue -Riesz space consisting of all the numerical valued r.v. \( \nu \) having a finite norm \( ||\nu||_{\Omega,p} = \left[ \mathbb{E} |\nu|^p \right]^{1/p} = \left[ \int_{\Omega} |\nu(\omega)|^p \, P(d\omega) \right]^{1/p} \).

Then under formulated restrictions

\[
|| \xi[X] ||_{L_p(\Omega)} \leq \int_X ||\xi(x)||_{L_p(\Omega)} \cdot \mu(dx).
\]  
(5)

As other spaces may be considered, e.g. Marcinkiewicz, Lorentz ones. Let us bring an interest (in our opinion) example. The particular case of the classical Lorentz quasi - norm (and correspondent space) for the random variable \( \phi \) is defined as follows

\[
||\phi||_{L^{q,\infty}} \overset{def}{=} \sup_{t \geq 0} \left[ t^q T_\phi(t) \right]^{1/q}.
\]

To be more precisely, there exists an actually norm which is equivalent to the described before quasi - norm \[21\].

We derive applying these spaces.

**Proposition 2.2.** Suppose for the introduced r.f \( \xi(x) \)

\[
\sup_{x \in X} T_{\xi(x)}(t) \leq t^{-q}, \ t \geq 1, \ q = \text{const} > 1.
\]

Then

\[
\exists C = C(q) < \infty, \ \Rightarrow \ T_{\xi[X]}(t) \leq C \ t^{-q}, \ t \geq 1.
\]

Let us consider an important case for the r.v. having in general case an exponential decreasing tail of distribution.

**Grand Lebesgue Spaces.**

Let \( b = \text{const}, 1 < b \leq \infty \). Let also \( \psi = \psi(p), \ p \in (1, b) \) be certain numerical valued measurable strictly positive: \( \inf_{p \in [1,b]} \psi(p) > 0 \) function, not necessary to be bounded. Denotation: \( \text{Dom}(\psi) \overset{def}{=} \{ p : \psi(p) < \infty \} \),

\[
(1, b) := \text{supp}(\psi); \ \Psi[1,b] := \{ \psi : \text{supp}(\psi) = (1, b) \},
\]

\[
\Psi \overset{def}{=} \bigcup_{b>1} \Psi[1,b].
\]
Definition 2.1., see e.g. [15], [8], [10]. Let the function \( \psi(\cdot) \in \Psi[1, b] \), which is named as generating function for introduced after space. The so-called Grand Lebesgue Space \( G\psi \) is defined as a set of all random variables (measurable functions) \( \tau \) having a finite norm

\[
||\tau||_{G\psi} \overset{\text{def}}{=} \sup_{p \in (1, b)} \left\{ \frac{||\tau||_{L_p(\Omega)}}{\psi(p)} \right\}.
\]  

(6)

The particular case of these spaces and under some additional restrictions on the generating function \( \psi = \psi(p) \) correspond to the so-called Yudovich spaces, see [22], [23]. These spaces was applied at first in the theory of Partial Differential Equations (PDE), see [5], [6].

These spaces are complete Banach functional rearrangement invariant; they are investigated in many works, see e.g. [7], [8], [9], [10], [11], [12], [13], [14], [15], [16], [17], [18], [19]. It is important for us in particular to note that there is exact of course up to finite multiplicative constant interrelations under certain natural conditions on the generating function between belonging the r.v. \( \tau \) to this space and it tail behavior. Indeed, assume for definiteness that \( \tau \in G\psi \) and moreover \( ||\tau||_{G\psi} = 1 \); then

\[
T_\tau(t) \leq \exp\{-h^*(\ln t)\}, \quad t \geq e,
\]  

(7)

where \( h(p) = h[\psi](p) := p \ln \psi(p) \) and \( h^*(\cdot) \) is famous Young - Fenchel (Legendre) transform of the function \( h(\cdot) : \]

\[
h^*(u) \overset{\text{def}}{=} \sup_{p \in \text{Dom}(\psi)} (pu - h(p)).
\]

Inversely, let the tail function \( T_\tau(t), \ t \geq 0 \) be given. Introduce the following so-called natural function generated by \( \tau \)

\[
\psi_\tau(p) \overset{\text{def}}{=} \left[ p \int_0^\infty t^{p-1} T_\tau(t) \ dt \right]^{1/p} = ||\tau||_{L_p(\Omega)},
\]  

(8)

if it is finite for some value \( b \in (1, \infty] \), following, it is finite at last for all the values \( p \in [1, b) \).

As long as

\[
E|\tau|^p = p \int_0^\infty t^{p-1} T_\tau(t) \ dt = \psi_\tau^p(p), \ p \in [1, b),
\]

we conclude that if the last natural for the r.v. \( \tau \) function \( \psi_\tau(p) \) is finite inside some non-trivial segment \( p \in [1, b), \ 1 < b \leq \infty \), then

\[
\tau \in G\psi_\tau; \quad ||\tau||_{G\psi_\tau} = 1.
\]
Further, let the estimate (7) be given. Suppose in addition that the generating function \( \psi = \psi(p), \ p \in \text{Dom}(\psi) \) is continuous and suppose in the case when \( b = \infty \)

\[
\lim_{p \to \infty} \frac{\psi(p)}{p} = 0. \tag{9}
\]

Then the r.v. \( \tau \) belongs to the Grand Lebesgue Space \( G\psi : \)

\[
||\tau||_{G\psi} \leq K[\psi] < \infty, \tag{10}
\]

see e.g. [17].

These conditions on the generating function \( \psi(\cdot) \) are satisfied for example for the functions \( \psi_{m,L}(p) \) of the form

\[
\psi_{m,L}(p) = p^{1/m} L(p), \ m = \text{const} > 1, \ b = \infty, \tag{11}
\]

where \( L = L(p) \) be some continuous strictly positive slowly varying at infinity function such that

\[
\forall \theta > 0 \Rightarrow \sup_{p \geq 1} \left[ \frac{L(p^\theta)}{L(p)} \right] = C(\theta) < \infty. \tag{12}
\]

For instance, \( L(p) = [\ln(p + 1)]^r, \ r \in R. \)

We conclude that under formulated restrictions the r.v. \( \tau \) belongs to the space \( G\psi_{m,L} : \)

\[
\sup_{p \geq 1} \left\{ \frac{||\tau||_{p,\Omega}}{\psi_{m,L}(p)} \right\} = C(m, L) < \infty \tag{13}
\]

if and only if

\[
T_x(u) \leq \exp\left( -C_2(m, L) \frac{u^m}{L(u)} \right), \ u \geq e, \ \exists \ C_2(m, L) > 0. \tag{14}
\]

A very popular example of these spaces forms the so-called subgaussian space \( \text{Sub} = \text{Sub}(\Omega) ; \) it consists on the subgaussian random variables, for which \( \psi(p) = \psi_2(p) := \sqrt{p} : \)

\[
||\tau||_{\text{Sub}} = ||\tau||_{G\psi_2} \overset{\text{def}}{=} \sup_{p \geq 1} \left[ \frac{||\tau||_{p,\Omega}}{\sqrt{p}} \right]. \tag{15}
\]

The r.v. \( \tau \) belongs to the subgaussian space \( \text{Sub}(\Omega) \) iff

\[
\exists C > 0 \ \Rightarrow \ T_x(u) \leq \exp(-Cu^2), \ u \geq 0. \tag{16}
\]

**Remark 2.1.** As a rule, on the the r.v. \( \tau \) from the spaces \( G\psi_{m,L} \) is imposed the condition of centering: \( E\tau = 0. \)

Another examples. Suppose that the r.v. \( \tau \) be such that
\[ T_{\tau}(t) \leq T^{\beta,\gamma,L}(t), \ \beta > 1, \ \gamma > -1, \ L = L(t), \]

where

\[ T^{\beta,\gamma,L}(t) \overset{\text{def}}{=} t^{-\beta} (\ln t)^{\gamma} L(\ln t), \ \ t \geq e \]

and \( L = L(t), \ t \geq e \) be as before slowly varying at infinity positive continuous function. It is known \([17]\) that as \( p \in [1, \beta) \)

\[ \psi_{\tau}(p) = ||\tau||_p \leq C_1(\beta, \gamma, L) (\beta - p)^{-(\gamma + 1)\beta} L^{1/\beta}(1/(\beta - p)), \]  \(\text{(17)}\)

and conversely, if the relation (17) there holds, then

\[ T_{\tau}(t) \leq C_7(\beta, \gamma, L) T^{\beta,\gamma+1,L}(t). \]

Herewith both this estimations are unimprovable.

**Theorem 2.1.** Denote for the random field \( \xi(x), \ x \in X \)

\[ Q(t) := \sup_{x \in X} T_{\xi(x)}(t), \ t \geq 0, \]

\[ g_0(p) := \left[ p \int_0^\infty t^{p-1} Q(t) \ dt \right]^{1/p}, \]

\[ g(p) := p \ln g_0(p), \]

and suppose \( \exists b \in (1, \infty) \Rightarrow g(b) < \infty. \) We assert

\[ T_{\xi[X]}(t) \leq \exp \left( -g^*(\ln t) \right), \ t \geq e. \]  \(\text{(18)}\)

**Proof.** We have

\[ T_{\xi(x)}(t) \leq Q(t), \ x \in X, \ t \geq 0. \]

Therefore the random variables \( \xi(x), \ x \in X \) belongs to the unit ball of the Grand Lebesgue Space \( G_{g_0} : \)

\[ \sup_{x \in X} ||\xi(x)||_{G_{g_0}} \leq 1. \]

It remains to apply the proposition (7).

**Remark 2.2.** A more general version: assume that there exists a finite a.e. and non-negative measurable numerical valued function \( \theta = \theta(x), \ x \in X \) such that

\[ T_{\xi(x)}(t) \leq \exp \left\{ -h^*_\psi[\ln(t/\theta(x))] \right\}, \ t \geq e, \]
then

$$||\xi(x)||G\psi \leq C_4[\psi] \theta(x), \ C_4[\psi] < \infty,$$

therefore

$$||\xi[X]||G\psi \leq C_4[\psi] \int_X \theta(x) \mu(dx),$$

with correspondent tail estimate

$$T_{\xi[X]} \leq \exp \left[ -h^*_\psi(\ln t/C_5) \right], \ t \geq eC_5,$$  \hspace{1cm} (19)

where

$$C_5 = C_4[\psi] \int_X \theta(x) \mu(dx),$$

if of course the last integral is finite.

**Example 2.1.** Suppose

$$\sup_{x \in X} T_{\xi(x)}(u) \leq \exp \left( -u^m/L(u) \right), \ u \geq e,$$  \hspace{1cm} (20)

where as before $m = \text{const} > 1$, $L = L(p)$ is some continuous strictly positive slowly varying at infinity function such that

$$\forall \theta > 0 \Rightarrow \sup_{p \geq 1} \left[ \frac{L(p^\theta)}{L(p)} \right] = C(\theta) < \infty.$$  \hspace{1cm} (21)

We conclude that under formulated above restrictions that $\exists C_5(m, L) > 0 \Rightarrow$

$$T_{\xi[X]}(u) \leq \exp \left\{ -C_5(m, L) u^m/L(u) \right\}, \ u \geq e.$$  \hspace{1cm} (22)

Obviously, the last estimate (22) is non-improvable, of course, up to multiplicative constant $C_5(m, L)$.

**Example 2.2.** Suppose now in the introduced notations and restrictions

$$\sup_{x \in X} T_{\xi(x)}(u) \leq T^{\beta,\gamma,L}(t), \ t \geq 1,$$  \hspace{1cm} (23)

We derive arguing similarly to the previous example

$$T_{\xi[X]}(u) \leq T^{\beta,\gamma+1,L}(C_6(\beta, \gamma, L) t), \ t \geq e, \ C_6 > 0,$$  \hspace{1cm} (24)

and this estimate is also non-improvable still in the case when the set $X$ consists in a single point [18].
Example 2.3. Let us show that the proposition of theorem 2.1 is not true if we replace the averaging onto the classical normalized sums of the centered random variables. Let \( \{\zeta_i, \; i = 1, 2, \ldots; \zeta = \zeta_i \} \) be a sequence if independent symmetrical distributed r.v. such that
\[
\forall y \geq 0 \implies T_\zeta(y) = \exp(-y^q), \; q = \text{const} > 2.
\]
Denote
\[
S_n := n^{-1/2} \sum_{i=1}^{n} \zeta_i; \; \sigma^2 = \sigma^2(q) \overset{\text{def}}{=} \text{Var}(\zeta) \in (0, \infty).
\]
We derive by virtue of CLT for all the positive values \( y \), say for \( y \geq 1 \)
\[
\sup_n P(S_n > y) \geq \lim_{n \to \infty} P(S_n > y) \geq \exp \left( -C_0 \; y^2 \right),
\]
\( C_0 = C_0(q) \in (0, \infty) \); so that the tails of distribution of the r.v. \( S_n \) are ”much heavier” as ones for the source variable \( \zeta \).

3 Conditional averaging.

Let as in the first section (2) \( \nu \overset{\text{def}}{=} \eta \{F\} \overset{\text{def}}{=} \mathbb{E}\eta/F, \) where \( F \) is some sub - sigma field of the source sigma algebra \( \mathcal{B} \).

Assume that
\[
T_\eta(t) \leq R(t), \; t \geq 0;
\]
where \( R = R(t) \) is non - negative bounded: \( R(t) \leq 1 \) non - increasing measurable function such that \( R(\infty) = 0 \). Introduce the \( \Psi \) function
\[
\delta(p) = \delta[R](p) \overset{\text{def}}{=} \left[ p \; \int_{0}^{\infty} t^{p-1} R(t) \; dt \right]^{1/p},
\]
and suppose \( \delta(\cdot) \in \Psi \); then
\[
\mathbb{E}|\eta|^p \leq \delta^p(p).
\]
Since the function \( g(y) = |y|^p, \; p \geq 1 \) is convex, one can apply the Jensen’s inequality for the conditional expectations
\[
\mathbb{E}|\nu|^p \leq \mathbb{E}|\eta|^p \leq \delta^p(p), \; p \in [1, b);
\]
following \( \nu \in G\delta \) and we obtain the inequality
\[
T_\nu(t) \leq \exp \left( -v^*(\ln \; t) \right), \; t \geq e,
\]
(25)
where
\[ v(p) = p \ln \delta(p), \ p \in \text{Dom}(\delta). \]

To summarize,

**Proposition 3.1.** We obtain under formulated notations and restrictions
\[ ||\nu||G\delta \leq 1, \] (26)
and hence the estimation (25) there holds.

The examples may be considered alike ones in the previous section, under at the same restrictions.

**Example 3.1.** If
\[ T\eta(u) \leq \exp \{ -u^m/L(u) \} , \ u \geq e, \] (27)
then
\[ T\nu(u) \leq \exp \{ -C_7(m, L) u^m/L(u) \} , \ u \geq e, \ C_7 > 0. \] (28)

**Example 3.2.** Suppose
\[ T\eta(u) \leq T^{\beta, \gamma, L}(t), \ t \geq 1, \ \beta > 1, \ \gamma > -1. \] (29)
We derive
\[ T\nu(u) \leq T^{\beta, \gamma+1, L}(C_8(\beta, \gamma, L) t), \ t \geq e, \ C_8 > 0, \] (30)
and this estimate is also essentially non-improvable, see e.g. [18].

**Example 3.3.** Let \( \Omega = (0, 1) \) equipped with the classical Lebesgue measure. Define the r.v. \( \eta = \omega^{-\alpha}, \ \omega \in (0, 1); \ \alpha = \text{const} \in (0, 1) \) and put
\[ F := \{ \emptyset, (0, 1/2], (1/2, 1), (0, 1) \}. \]
We have
\[ \mathbb{E}|\eta|^p = \frac{1}{1 - \alpha p}, \ 1 \leq p < 1/\alpha \]
and \( \mathbb{E}|\eta|^p = \infty, \ p \geq 1/\alpha. \) The r.v. \( \nu = \mathbb{E}\eta/F \) has a form
\[ \nu(\omega) = 2^{\alpha}/(1 - \alpha), \ \omega \in (0, 1/2] \]
and
\[ \nu(\omega) = (2 - 2^{\alpha})/(1 - \alpha), \ \omega \in (1/2, 1). \]
Thus, the r.v. \( \nu \) is bounded, despite that the source r.v. \( \eta \) has not all the moments \( E|\eta|^p, p \geq 1/\alpha \).

4 Applications to the martingale theory.

A. Uniform integrable martingales.

Suppose that there is certain filtration on the source probability sigma-field \( \mathcal{B} \), i.e. an increasing sequence of sigma-subfields \( \{F_n\} \) of canonical one \( \mathcal{B} \), and let \((\kappa_n, F_n), n = 1, 2, \ldots\) be an uniform integrable martingale:

\[
E\kappa_m/F_k = \kappa_k, \quad 1 \leq k \leq m
\]

We conclude by virtue of theorem J.Doob there exists with probability one a limit

\[
\kappa \overset{\text{def}}{=} \lim_{n \to \infty} \kappa_n. \quad (31)
\]

Assume that

\[
T_\kappa(t) \leq U(t), \quad t \geq 0,
\]

where \( U = U(t) \) is some non-negative bounded \( U(t) \leq 1 \) non-increasing function for which \( \lim U(t) = 0, \quad t \to \infty \). Introduce as before the following \( \Psi - \) function

\[
\rho(p) \overset{\text{def}}{=} \left[ p \int_0^\infty t^{p-1} U(t) \ dt \right]^{1/p},
\]

and we suppose \( \rho \in \Psi(b) \) for some value \( b \in (1, \infty] \).

We get on the basis of proposition 3.1 using the fact that \( \kappa_n = E\kappa/F_n \)

Proposition 4.1.

\[
||\kappa_n||G\rho \leq 1 \quad (32)
\]

with correspondent tail estimation (7).

Further, define the following finite a.e. random variable

\[
\hat{\kappa} := \sup_n \kappa_n
\]

and a new \( \Psi - \) function
\[ \hat{\rho}(p) := p/(p - 1) \cdot \rho(p), \; p \in (1, b). \]

**Proposition 4.2.**

\[ ||\hat{\kappa}||_G \hat{\rho} \leq 1, \quad (33) \]

with correspondent tail estimation.

**Proof** is quite alike to the previous one; one can apply the famous Doob’s inequality

\[ E|\hat{\kappa}|^p \leq \left[ \frac{p}{p-1} \right]^p \cdot \rho^p(p) = [ \hat{\rho}(p) ]^p. \]

**Remark 4.1.** The proposition 4.2 allows a simple (particular) inversion. Assume namely that the estimation (33) is satisfied. Then the r.v. \{\kappa_n\} are uniform integrable and, following, by virtue of theorem J.Doob there exists a limit a.e.

\[ P(\lim_{n \to \infty} \kappa_n = \kappa) = 1. \quad (34) \]

It follows from (34) and (33) that in turn

\[ \sup_n ||\kappa_n||_G \hat{\rho} < \infty. \]

**B. General case: a non-uniform integrable martingales.**

Let again \((\kappa_n, F_n)\) be a martingale; we do not suppose in this subsection that it is uniform integrable. Then the sequence \(\kappa_n\) must be normed; and as it is noted in [20] the natural norming sequence may be chosen as a its square variation

\[ [\kappa_n]^2 \overset{\text{def}}{=} \kappa_1^2 + \sum_{i=2}^{n} (\kappa_i - \kappa_{i-1})^2, \; n \geq 2. \quad (35) \]

But the square variation sequence is random; therefore we offer its expectation as a capacity of norming sequence

\[ \sigma_n^2 \overset{\text{def}}{=} E[\kappa_n]^2, \; n \geq 2; \quad \sigma_1^2 := E\kappa_1^2. \quad (36) \]

*It will be presumed further that \(\sigma_n \in (0, \infty), \; n \geq 1.\)*

For instance, if our martingale may be represented as a sum of the centered independent r.v.

\[ \kappa_n = \sum_{j=1}^{n} \epsilon_j, \quad F_n = \sigma\{ \epsilon_j, \; 1 \leq j \leq n \}, \]
such that $\text{Var}(\epsilon_j) < \infty$, then

$$\sigma_n^2 = \sum_{j=1}^{n} \text{Var}(\epsilon_j).$$

Further, suppose as above that

$$\sup_n T_{\kappa_n/\sigma_n}(t) \leq W(t), \quad t \geq 1,$$

where $W(\cdot)$ is non-negative bounded $W \leq 1$ non-increasing function such that $W(\infty) = 0$. Define

$$v(p) := \left[ p \int_0^\infty t^{p-1} W(t) \, dt \right]^{1/p}, \quad \hat{v}(p) := pv(p).$$

**Proposition 4.3.**

One can apply the famous Burkholder's inequality [2]

$$\left\| \max_{k=1,2,\ldots,n} \kappa_k \right\|_p \leq p v(p) = \hat{v}(p),$$

or equally

$$\left\| \max_{k=1,2,\ldots,n} \kappa_k \right\| G\hat{v} \leq 1$$

with correspondent tail estimate (7).

5 Concluding remarks.

It is interest in our opinion to generalize obtained results on the variables, and martingales, taking values in Banach spaces.
