Suppression of superconducting parameters by correlated quasi-two-dimensional magnetic fluctuations

A. E. Koshelev

Materials Science Division, Argonne National Laboratory, Argonne, Illinois 60439

(Dated: June 9, 2020)

We consider a clean layered magnetic superconductor in which a continuous magnetic transition takes place inside superconducting state. We assume that the exchange interaction between superconducting and magnetic subsystems is weak so that superconductivity is not destroyed at the magnetic transition. A representative example of such material is RbEuFe₄As₄. We investigate the suppression of the superconducting gap and superfluid density by correlated magnetic fluctuations in the vicinity of the magnetic transition. The influence of nonuniform exchange field on superconducting parameters is very sensitive to the relation between the magnetic correlation length, \( \xi_h \), and superconducting coherence length \( \xi_s \) defining the ‘scattering’ (\( \xi_h < \xi_s \)) and ‘smooth’ (\( \xi_h > \xi_s \)) regimes. As a small uniform exchange field does not affect the superconducting gap and superfluid density at zero temperature, smoothening of the spatial variations of the exchange field reduces its effects on these parameters. We develop a quantitative description of this ‘scattering-to-smooth’ crossover for the case of quasi-two-dimensional magnetic fluctuations realized in RbEuFe₄As₄. Since the magnetic-scattering energy scale is comparable with the gap in the crossover region, the standard quasiclassical approximation is not applicable and full microscopic treatment is required. We find that the corrections to both the gap and superfluid density increase proportionally to \( \xi_s \) until it remains much smaller than \( \xi_s \). In the opposite limit, when the correlation length exceeds the coherence length both parameters have much weaker dependence on \( \xi_h \). Moreover, the gap correction may decrease with increasing of \( \xi_s \) in the immediate vicinity of the magnetic transition if it is located at temperature much lower than the superconducting transition. We also find that the crossover between the two regimes is unexpectedly broad: the standard scattering approximation becomes sufficient only when \( \xi_s \) is substantially smaller than \( \xi_s \).

I. INTRODUCTION

Since the seminal work of Abrikosov and Gor’kov (AG)\(^{11}\) and its extensions\(^{2–4}\), the pair breaking by magnetic scattering has been established as a key concept in the physics of superconductivity. Its applications extend far beyond the original physical system for which the theory was developed, singlet superconductors with dilute magnetic impurities. In particular, the magnetic pair-breaking scattering strongly influences properties of superconducting materials containing an embedded periodic lattice of magnetic rare-earth ions. Several classes of such materials are known at present including magnetic Chevrel phases \( REM_2X_8 \) (\( RE=\)rare-earth element and \( X=\)S, Se), ternary rhodium borides \( RERh_4B_2\)\(^{2,3}\), the rare-earth nickel borocarbides \( RENi_2B_2C\)\(^{10,11}\) and recently discovered Eu-based iron pnictides\(^{12–16}\). Some of these compounds experience a magnetic-ordering transition inside the superconducting state. Depending on the strength of the exchange interaction between the rare-earth moments and conducting electrons, the magnetic transition may either destroy superconductivity or leave it intact. In any case, in the paramagnetic state, the fluctuating magnetic moments suppress superconductivity via magnetic scattering, similar to magnetic impurities. Near the ferromagnetic transition, the moments become strongly correlated which enhances the suppression. The AG theory has been generalized to describe this enhancement in several theoretical studies\(^{17–19}\). A straightforward generalization, however, is only possible when the magnetic correlation length \( \xi_h \) is shorter than the superconducting coherence length \( \xi_s \) and this condition was always assumed in all theoretical works. For a continuous magnetic transition, there is always temperature range where this condition is violated, see Fig. \( 1(a) \). A small uniform exchange field does not modify superconducting gap in clean materials at zero temperature\(^{10} \), because, in absence of free quasiparticles, the exchange field does not generate spin polarization of the Cooper-pair condensate. This observation indicates that, once the exchange field becomes smooth at the scale of coherence length, its efficiency in suppressing superconducting parameters at low temperatures diminishes. We can conclude that the existing treatments of the impact of correlated magnetic fluctuations on superconductivity are incomplete. A full theoretical description of this phenomenon requires consideration of the crossover between the ‘scattering’ and ‘smooth’ regimes illustrated in Fig. \( 1(a) \). For most magnetic superconductors, however, such full theory would be a mostly academic exercise, because the coherence length is typically much larger than the separation between magnetic ions. Consider, for example, the magnetic nickel borocarbide \( ErNi_2B_2C \), which has the superconducting transition at \( T_c \approx 11 \) K and magnetic transition at \( T_m \approx 6 K\)\(^{19} \). Its c-axis upper critical field has linear slope 0.3 T/K near \( T_c \)\(^{20} \), from which we can estimate the in-plane coherence length at \( T_c \) as \( \xi_s(T_c) \approx 18 \) nm which is \( \approx 54 \) times larger than the distance between the \( Er^{3+} \) moments. Therefore, in this and similar materials the magnetic correlation length exceeds the coherence length only within an extremely narrow tempera-
ture range near the magnetic transition. The situation is very different, however, in Eu-based layered iron pnictides, such as RbEuFe$_4$As$_4$. The latter material has the superconducting transition at 36.5 K and the magnetic transition at 15K. The magnetism is quasi-two-dimensional: the Eu$^{2+}$ moments have strong ferromagnetic interactions inside the magnetic layers with easy-plane anisotropy and weak interactions between the magnetic planes leading to helical interlayer order. Due to the quasi-two-dimensional nature of magnetism, the in-plane magnetic correlation length smoothly grows within an extended temperature range. Another relevant material’s property is a very short in-plane coherence length, $\sim 1.5$–2 nm, which is only 4–6 times larger than the distance between the magnetic ions. As a consequence, contrary to most magnetic superconductors, the magnetic correlation length exceeds the coherence length within a noticeable temperature range near the magnetic transition. Therefore, for the magnetic iron pnictides, the crossover between the ‘scattering’ and ‘smooth’ regimes is very relevant. Recent vortex imaging in RbEuFe$_4$As$_4$ with scanning Hall-probe spectroscopy revealed a significant increase of the London penetration depth in the vicinity of the magnetic transition. This suggests that the exchange interaction between Eu$^{2+}$ moments and Cooper pairs leads to substantial suppression of superconducting parameters near $T_m$.

The goal of this paper is to develop a quantitative theoretical description of the influence of correlated magnetic fluctuations on the superconducting gap and supercurrent response with a proper treatment of the crossover at $\xi_h \sim \xi_s$. The problem occurs to be technically challenging because in the crossover region the probability of magnetic scattering varies at the energy scale comparable with the temperature or the gap. This forbids the standard energy integration necessary for the quasiclassical approximation and requires a full microscopic consideration. In this consideration, one has to include the self-energy correction to the electronic spectrum and maintain the energy dependence of the scattering probability. As this accurate analysis is rather complicated, we utilize several simplifying assumptions. We limit ourselves to the case of weak exchange interaction and consider only the lowest-order corrections. We also assume the static approximation for magnetic fluctuations. This assumption is justified when typical frequency scale for magnetic fluctuations is smaller than the superconducting gap. Due to the critical slowing down, this always becomes valid sufficiently close to the transition. In the scattering regime, the dynamic effects have been investigated in several theoretical papers, see, e.g., [17,20,22]. The behavior is also sensitive to the dimensionality of magnetic fluctuations. Having in mind application to layered magnetic superconductors, such as RbEuFe$_4$As$_4$, we assume quasi-two-dimensional magnetic fluctuations. In this case the discussed effects are more pronounced than for three-dimensional magnetic fluctuations.

The paper is organized as follows. In Sec. [III] we introduce the model for layered magnetic superconductors. In Sec. [III] we evaluate the self energy caused by scattering by correlated magnetic fluctuations for arbitrary relation between the magnetic correlation length and coherence length and develop a quantitative description of the crossover between the scattering and smooth regimes. In Sec. [IV] we use these results to evaluate the exchange correction to the gap. In Sec. [V] we evaluate the leading correction to the electromagnetic kernel accounting for the vertex correction. Also, in Appendix [B] this correction is evaluated in the scattering regime with quasiclassical approach. Finally, in Sec. [VI] we discuss the results and illustrate them by plotting representative temperature dependences for the parameters roughly corresponding to RbEuFe$_4$As$_4$.

II. MODEL

We consider a layered material composed of superconducting and magnetic layers described by the Hamiltonian

$$\hat{\mathcal{H}} = \hat{\mathcal{H}}_S + \hat{\mathcal{H}}_M + \hat{\mathcal{H}}_{MS},$$

where

$$\hat{\mathcal{H}}_S = \sum_{n,\sigma} \xi^{2D}(p) a_{n,\sigma}^\dagger(p) a_{n,\sigma}(p) + \sum_{n,\sigma} \Delta n_{n,\sigma} a_{n,\sigma}^\dagger(-p) + \Delta^* n_{n,\sigma} a_{n,\sigma}(p)$$

$$\hat{\mathcal{H}}_M = \sum_{n,\sigma} \sum_{\alpha,\beta} \hat{\mathcal{H}}_{Mn} r J_{mn}(r-R) S_{\alpha\beta}(R) a_{\alpha\beta}(r)$$

is the standard BCS Hamiltonian describing a layered superconductor. Here $\sigma$ is spin index, $\xi^{2D}(p) = \varepsilon^{2D}(p) - \mu$ is the single-layer spectrum, $t_\perp$ is the interlayer hopping integral, $\Delta$ is the superconducting gap. The full 3D spectrum for this model is $\hat{\mathcal{S}} = \xi^{2D}(p) + 2 t_\perp \cos(p, s)$. However, its exact shape has a very little effect on further consideration. The second term, $\hat{\mathcal{H}}_M$, describes the quasi-two-dimensional magnetic subsystem leading to a continuous phase transition at $T_m$. The last term

$$\hat{\mathcal{H}}_{MS} = \sum_{n,\sigma,\alpha} \int \frac{d^2 r}{R} J_{mn}(r-R) S_{\alpha\beta}(R) \sigma_{\alpha\beta} a_{n,\alpha}^\dagger(r) a_{n,\beta}(r)$$

describes the interaction between the magnetic and superconducting layers with the strength set by the non-local exchange constants $J_{mn}(r-R)$. Here the index $m$ marks magnetic layers, $\sigma_{\alpha\beta}$ is Pauli-matrix vector, and summation is assumed over the spin indices $\alpha$ and $\beta$. We can rewrite the interaction term as

$$\hat{\mathcal{H}}_{MS} = - \sum_n \int \frac{d^2 r}{R} a_{n,\alpha}^\dagger(r) \hat{\mathcal{H}}_{n}(r) \sigma_{\alpha\beta} a_{n,\beta}(r),$$
The influence of the fluctuating magnetic moments on superconductivity is very different in the regions $\xi_h > \xi_s$ and $\xi_h < \xi_s$. In the case $\xi_h \gg k_F^{-1}$ with $h k_F = p_F$. The small circle illustrates the small-angle scattering on magnetic fluctuations with the range $|p - p'| \sim \hbar/\xi_h$ and the ring with width $\hbar/\xi_s$ illustrate the range relevant for superconductivity.

The fluctuating part of the exchange field also depends on time. We assume that the time scales of magnetic fluctuations exceeds time scales relevant for superconductivity and employ the quasistatic approximation. This assumption is justified near the transition due to the critical slowing down. The fluctuating part is characterized by the correlation function

$$\langle \tilde{h}(r)\tilde{h}(r') \rangle = \sum_{m,R} J_{nm}(r-R)S_m(R) \delta_{nm}$$

is the effective exchange field acting on spins of conducting electrons. It can be split into the average part $\bar{h}$ due to either polarization of the moments by the magnetic field or spontaneous magnetization in the ordered state and the fluctuating part $\h_n(r)$, $\h_n(r) = \bar{h} + \tilde{h}_n(r)$,

$$\tilde{h} = -\sum_{m,R} J_{nm}(r-R)\tilde{S},$$

$$\tilde{h}_n(r) = -\sum_{m,R} J_{nm}(r-R)\tilde{S}_m(R).$$

The fluctuating part of the exchange field also depends on time. We assume that the time scales of magnetic fluctuations exceeds time scales relevant for superconductivity and employ the quasistatic approximation. This assumption is justified near the transition due to the critical slowing down. The fluctuating part is characterized by the correlation function

$$\langle \tilde{h}(r)\tilde{h}(r') \rangle = \sum_{m,R} \sum_{m',R'} J_{nm}(r-R)J_{n'm'}(r'-R') \langle \tilde{S}_m(R)\tilde{S}_m(R') \rangle.$$ 

The logarithmic divergency $K_0(r/\xi_h) \propto \ln(\xi_h/r)$ has to be terminated at the distance between neighboring
moments \( r \sim a \). Since the function \( f_{\hbar}(r/\xi_h) \) is normalized by the condition \( f_{\hbar}(0) = 1 \), this means that \( C_h \approx 2\pi/\ln(\xi_h/a) \).

We will use the Green’s functions formulation of the superconductivity theory. For investigation of scattering by the magnetic fluctuations, we have to operate with the matrix \( 4 \times 4 \) Green’s function:

\[
\hat{G}(1, 2) = -\left( \frac{\langle T_t \hat{a}_b^{\dagger}(1) a_{b}(2) \rangle}{\langle T_t \hat{a}_b^{\dagger}(1) a_{b}(2) \rangle} \right).
\]

We will expand it with respect to the fluctuating exchange field. The unperturbed Green’s function can be written as

\[
\hat{G}_0 = -\frac{i\omega_n \hat{r}_0 + \xi_p \hat{r}_z}{\omega_n^2 + \xi_p^2 + \Delta^2}
\]

where \( \hat{r}_0 \) and \( \hat{r}_z \) are the Pauli matrices in the spin and Nambu space, respectively. We see that the unperturbed Green’s function can be expanded as \( \hat{G} = \sum_{ab} \hat{r}_a \hat{r}_b G_{ab} \) and, without the uniform exchange field, the only nonzero components are \( 00, 0z \) and \( yy \). For the single-band BCS model, the gap equation is

\[
\Delta = U T \sum_{\omega_n} \int \frac{d^3p}{(2\pi)^3} G_{yy}(p),
\]

where \( U \) is the pairing interaction.

### III. SCATTERING BY FLUCTUATING EXCHANGE FIELD

The Green’s function renormalized by scattering is

\[
\hat{G} = \hat{G}_0 - \hat{\Sigma}
\]

where \( \hat{G}_0 = i\omega_n \hat{r}_0 - \xi_p \hat{r}_z + \Delta \hat{r}_y \) and

\[
\hat{\Sigma}(p) = \int \frac{d^3q}{(2\pi)^3} \langle |\hat{h}_{q, i}|^2 \rangle \hat{a}_i \hat{G}(p + q) \hat{a}_i
\]

is the self-energy due to the scattering on the fluctuating exchange field with \( \hat{a}_i = (\hat{r}_z, \hat{r}_x, \hat{r}_y, \hat{r}_x, \hat{r}_z, \hat{r}_y) \). Using the expansion \( \hat{\Sigma}(p) = \sum_{ab} \Sigma_{ab} \hat{r}_a \hat{r}_b \), we obtain that the relevant components with \( ab = 00, 0z, yy \) are

\[
\Sigma_{00}(p) = \int \frac{d^3p'}{(2\pi)^3} \langle |\hat{h}_{p-p'}|^2 \rangle G_{00}(p'),
\]

with

\[
\Sigma_{00}(p) = -\int \frac{d^3p'}{(2\pi)^3} \langle |\hat{h}_{p-p'}|^2 \rangle \frac{i\omega_n}{\omega_n^2 + \xi_p^2 + \Delta^2}, \quad \Sigma_{0z}(p) = -\int \frac{d^3p'}{(2\pi)^3} \langle |\hat{h}_{p-p'}|^2 \rangle \frac{\xi_{p'}}{\omega_n^2 + \xi_p^2 + \Delta^2},
\]

and \( \Sigma_{yy}(p) = -\frac{\Delta}{i\omega_n} \Sigma_{00}(p) \).

The behavior of \( \hat{\Sigma}_p \) depends on the relation between three length scales: the magnetic correlation length \( \xi_m \), in-plane coherence length \( \xi_z \), and inverse Fermi wave vector \( k_F^{-1} \). Consider first limiting cases qualitatively. For very long correlations \( \xi_h > \xi_z \), we have a slowly varying exchange field. In this case, we can neglect \( p' \) dependence everywhere except \( \langle |\hat{h}_{p-p'}|^2 \rangle \) giving

\[
\hat{\Sigma}(p) \approx \frac{1}{2\tau_m} - \frac{i\omega_n \hat{r}_0 + \Delta \hat{r}_y \hat{r}_y}{\sqrt{\omega_n^2 + \Delta^2}}
\]

with the scattering rate

\[
\frac{1}{2\tau_m} = \int \frac{\pi dS_F}{(2\pi)^3 v_F} \langle |\hat{h}_{p-p'}|^2 \rangle,
\]

which accounts for possibility that the range of \( \langle |\hat{h}_{p-p'}|^2 \rangle \) may be much smaller than the Fermi-surface size. Note that, in contrast to the case of long correlations, Eq. (17), (i) the \( p \) dependence of \( \hat{\Sigma}(p) \) in Eq. (15) can be neglected and (ii) the \( \Sigma_{0z} \) component can be omitted. These are standard approximations of the AG theory. In the regime \( \xi_h > \xi_z \), the magnetic fluctuations give small-angle scattering, see illustration in Fig. 1(b). The dependence of the scattering rate on the correlation length following from Eq. (15) is sensitive to the dimensionality of scattering. For three-dimensional scattering, the scattering rate increases logarithmically with \( \xi_h \). In our quasi-2D case, we assume that scattering occurs in the whole range of \( p_z - p'_z \) but with small change of the in-plane momentum. In this case Eq. (19) gives

\[
\frac{1}{2\tau_m} = \frac{2\pi}{\pi dS_F} \frac{\int \pi dq}{(2\pi)^3 v_F} C_h \hat{h}_0^2 \hat{\xi}_h = \frac{C_h \hat{h}_0^2 \hat{\xi}_h}{4v_F^2}.
\]

In general case, the product \( C_h \hat{h}_0^2 \hat{\xi}_h \) in this formula and in several results below, can be directly computed from the correlation function of the exchange field as

\[
C_h \hat{h}_0^2 \hat{\xi}_h = \int_0^\infty dr \langle \hat{n}(r) \hat{n}(0) \rangle.
\]

This relation allows evaluation of the scattering rate from the spin-spin correlation function, see Eq. (5), which can be computed for a particular magnetic model. We can
see that in quasi-2D case the scattering rate increases linearly with $\xi_h$, much faster than in 3D case. For completeness, we also present here the result for very short correlation $\xi_h k_F < 1$ when magnetic fluctuations scatter at all angles. In this case we can replace $|\hat{h}_{p-p'}|^2$ with $|\hat{h}_0|^2$ and obtain the Abrikosov-Gor'kov result for uncorrelated magnetic impurities

$$\frac{1}{2\tau_m} = C_n v h_0^2 s \xi_h^2, \quad (22)$$

where $\nu$ is the density of states. In particular, for quasi-2D electronic spectrum $\nu = m/(2\pi h^2 s)$ where $m$ is the effective mass.

Away from the magnetic transition, the magnetic correlation length $\xi_h$ is of the order of separation between the magnetic moments $a$. For a continuous magnetic transition inside the superconducting state, the magnetic correlation length rapidly increases for $T \to T_m$ and at some point exceeds the coherence length. At this crossover the impact of magnetic fluctuations on superconductivity modifies qualitatively. We now quantify the crossover the impact of magnetic fluctuations on superconductivity modifies qualitatively. We now quantify the crossover between the regimes $\xi_h > \xi_s$, Eq. (17), and $\xi_h < \xi_s$, Eqs. (18) and (20). It is important to note that in the second (scattering) regime only two components of $\Sigma$ are essential, 00 and $yy$. In the first regime, however, the 0z component describing spectrum renormalization has to be included. The latter component obviously also has to be taken into account in the description of the crossover. First, we consider the 00 component (the 00 and $yy$ components are related as $\Sigma_{yy} = -\Delta/\Sigma_{00}$). As the scattering in the regime $k_F\xi_h \gtrsim 1$ is small angle, we need to consider only a small region at the Fermi surface near the initial momentum $p$. Selecting $x$ axis along this momentum and $y$ axis in the perpendicular direction (see Fig. 1(b)) and using $|\langle \hat{h}_{\mathbf{q}} \rangle|^2$ in Eq. (10), we transform Eq. (10a) as

$$\Sigma_{00}(p) = -\int \frac{dp'_x dp'_y}{(2\pi)^2} \frac{C_n h_0^2 \xi_h^2}{1 + \xi_h^2 (p'_x - p_x)^2 + \xi_h^2 p_y'^2} \times \frac{i \omega_n}{\omega_n^2 + v_F^2 (p'_x - p_F)^2 + \Delta^2}. \quad (23)$$

Integrating with respect to $p'_y$, we obtain

$$\Sigma_{00}(p) = -\frac{C_n h_0^2 \xi_h^2}{4 \pi} \int_{-\infty}^{\infty} dp'_x \frac{1}{\sqrt{1 + \xi_h^2 p'_x^2}} \times \frac{i \omega_n}{\omega_n^2 + v_F^2 (p'_x - p_F)^2 + \Delta^2}$$

$$= -\frac{C_n h_0^2}{4 \pi} \frac{i \omega_n}{\omega_n^2 + \Delta^2} U(\delta k_x, g_n), \quad (24)$$

where $\delta p_x = p_x - p_F,$

$$g_n = \frac{v_F/\xi_h}{\sqrt{\omega_n^2 + \Delta^2}}; \quad \delta k_x = \frac{v_F (p_x - p_F)}{\sqrt{\omega_n^2 + \Delta^2}} = \frac{\xi_p}{\sqrt{\omega_n^2 + \Delta^2}}, \quad (25)$$

and the reduced function $U(k, g)$ is defined by the integral

$$U(k, g) = \int_{-\infty}^{\infty} \frac{du}{\sqrt{1 + u^2}} \frac{1}{1 + (gu + k)^2},$$

which can be taken analytically giving

$$U(k, g) = \text{Re} \left[ W(k, g) \right], \quad (26)$$

$$W(k, g) = \frac{2}{\sqrt{(ik+1)^2 - g^2}} \ln \left( \frac{ik+1+\sqrt{(ik+1)^2 - g^2}}{g} \right).$$

We note that the $k$ dependence of the function $U(k, g)$ corresponding to the $\xi_p$ dependence of the self energy is essential only for $g \lesssim 1$. The value of the function $U(k, g)$ at $k = 0$ has the simple analytical form

$$U(0, g) = \begin{cases} \frac{2}{\sqrt{1-g^2}} \ln \frac{1+\sqrt{1-g^2}}{g} & \text{for } g < 1 \\ \frac{2}{\sqrt{g^2-1}} \arctan \sqrt{g^2-1} & \text{for } g > 1. \end{cases}$$

The asymptotic $U(0, g) \propto 1/g$ for $g \gg 1$ corresponds to the scattering regime. Eqs. (18) and (20). In this limit the $k$ dependence of the function $U(k, g)$ can be neglected. On the other hand, the asymptotic for $g \ll 1$ is

$$U(k, g) \simeq 2 \left[ \frac{1}{1+k^2} \ln \left( \frac{2 \sqrt{1+k^2}}{g} \right) + \frac{k}{1+k^2} \arctan k \right].$$

It corresponds to the uniform-field result in Eq. (17) only for the main logarithmic term. Additional terms appear because the correlation function $\langle \hat{h}_\mathbf{q}(r) \hat{h}_\mathbf{q}(r') \rangle$ in Eq. (9) is not a constant at $r < \xi_h$ but increases logarithmically as $\ln (\xi_h/r)$.

As mentioned above, for the proper description of the crossover at $\xi_h \sim \xi_s$, we also need to take into account the 0z component of the self energy,

$$\Sigma_{0z}(p) = -\frac{C_n h_0^2 \xi_h^2}{4 \pi} \int_{-\infty}^{\infty} dp'_x \frac{1}{\sqrt{1 + \xi_h^2 p'_x^2}} \times \frac{v_F (p'_x - p_F)}{\omega_n^2 + v_F^2 (p'_x - p_F)^2 + \Delta^2}. \quad (27)$$

Following the same route as in derivation of Eq. (24), we present it as

$$\Sigma_{0z}(p) = -\frac{C_n h_0^2}{4 \pi} \frac{1}{\sqrt{\omega_n^2 + \Delta^2}} V(\delta k_x, g_n), \quad (28)$$

where the parameters $g_n$ and $\delta k_x$ are defined in Eq. (25),

$$V(k, g) = \int_{-\infty}^{\infty} \frac{du}{\sqrt{1+u^2}} \frac{1}{1+(gu+k)^2} = -\text{Im} \left[ W(k, g) \right], \quad (29)$$
and the function $W(k,g)$ is defined in Eq. (26). In particular, for $g \to 0$

$$V(k,g) \simeq \frac{2}{1 + k^2} \left[ k \ln \left( \frac{2}{g} \right) - \arctan k \right].$$

As follows from Eq. (14), the renormalized Green's function can be obtained by substitutions $i\omega_n \to i\tilde{\omega}_n = i\omega_n - \Sigma_{00}$, $\Delta \to \tilde{\Delta} = \Delta - \Sigma_{yy}$, and $\xi_p \to \tilde{\xi}_p = \xi_p + \Sigma_0$. The renormalized frequency, gap, and spectrum can be written as

$$\tilde{\omega}_n = \omega_n(1 + \alpha_n), \quad \tilde{\Delta} = \Delta_0(1 - \alpha_n), \quad \tilde{\xi}_p = \xi_p(1 - \beta_n) \quad (30)$$

with

$$\alpha_n = \frac{C_h h_0^2 U(\delta k_x, g_n)}{4\pi \omega_n^2 + \Delta_0^2}, \quad \beta_n = \frac{C_h h_0^2 V(\delta k_x, g_n) / \xi}{4\pi \sqrt{\omega_n^2 + \Delta_0^2}}. \quad (31)$$

With derived results for the self-energy in Eqs. (24) and (28), we proceed with evaluation of correction to the gap parameter from Eq. (13).

### IV. CORRECTION TO THE GAP

The superconducting gap is the most natural parameter characterizing the strength of superconductivity at a given temperature. In this section, we calculate the suppression of this parameter by correlated magnetic fluctuations. The key observation is that a small uniform exchange field has no influence on the gap at zero temperature. Therefore, one can expect that the suppression caused by correlated magnetic fluctuations at low temperatures diminishes when the magnetic correlation length exceeds the superconducting coherence length.

The gap equation in Eq. (13) is determined by the integral

$$\mathcal{I} = \int d^3p \frac{\Omega_{yy}(p)}{(2\pi)^3} = \nu \int_{-\infty}^{\infty} d\xi \frac{\tilde{\Delta}}{\omega_n^2 + \xi^2 + \Delta_0^2}, \quad (32)$$

where the parameters with “~” are defined in Eqs. (30) and (31). We evaluate the linear correction to $\mathcal{I}$ with respect to $\alpha_n, \beta_n \propto h_0^2$ as

$$\delta \mathcal{I} = -\nu \int_{-\infty}^{\infty} d\xi \frac{\Delta_0}{\omega_n^2 + \xi^2 + \Delta_0^2} \times \left( \frac{2\alpha_n (\omega_n^2 - \Delta_0^2) - 2\beta_n \xi^2}{(\omega_n^2 + \xi^2 + \Delta_0^2)} \right).$$

Making the substitution $\xi = z\sqrt{\omega_n^2 + \Delta_0^2}$, we transform this correction to the following form

$$\delta \mathcal{I} = -\frac{C_h h_0^2}{4\pi} \frac{\Delta_0}{\omega_n^2 + \Delta_0^2} \left[ \int_{-\infty}^{\infty} dz \frac{W(z, g_n) (z - i)^2 + 4\omega_n^2 \omega_n^2}{(z^2 + 1)^2} \right]. \quad (33)$$

Calculation of the integral described in appendix A yields the result

$$\delta \mathcal{I} = -\frac{C_h h_0^2}{4\pi} \frac{\Delta_0}{\omega_n^2 + \Delta_0^2} \left[ \int_{-\infty}^{\infty} dz \frac{\omega_n^2 (4 - g_n^2) - 2\Delta_0^2}{(4 - g_n^2) g_n} \ln \left( 2 + \sqrt{4 - g_n^2} \right) \right]. \quad (34)$$

The corrected equation for the gap $\Delta = UT \sum_\omega \mathcal{I}_0 + \delta \mathcal{I}$ with $\mathcal{I}_0 = \pi / \sqrt{\omega_n^2 + \Delta_0^2}$ gives the gap correction caused by the nonuniform exchange field

$$\tilde{\Delta} = -\frac{C_h h_0^2 T}{\omega_n^2 + \Delta_0^2} \left[ \int_{-\infty}^{\infty} dz \frac{\omega_n^2 (4 - g_n^2) - 2\Delta_0^2}{(4 - g_n^2) g_n} \ln \left( 2 + \sqrt{4 - g_n^2} \right) \right].$$

Substituting the definition of $g_n$ in Eq. (25), we finally obtain

$$\tilde{\Delta} = -\left[ \frac{C_h h_0^2 T}{\omega_n^2 + \Delta_0^2} \right] \left[ \int_{-\infty}^{\infty} dz \frac{\omega_n^2 (4 - g_n^2) - 2\Delta_0^2}{(4 - g_n^2) g_n} \ln \left( 2 + \sqrt{4 - g_n^2} \right) \right],$$

with $\Omega_n = \sqrt{\omega_n^2 + \Delta_0^2}$. and the magnetic-scattering energy scale $\varepsilon_h = v_F / \xi_h$. Introducing the reduced variables

$$\tilde{T} = 2\pi T / \Delta_0(T), \quad \tilde{\omega}_n = \tilde{T}(n + 1/2), \quad \alpha_n = \epsilon_h(T) / 2\Delta_0(T) = \xi_s(T) / \xi_h(T)$$

with $\xi_s(T) = v_F / 2\Delta_0(T)$, and using the estimate $C_h \approx 2\pi / \ln (\xi_s / a)$, we rewrite this result in the form convenient for numerical evaluation.
\[ \bar{\Delta}(T) = -\frac{h_0^2}{2\Delta_0(T) \ln (\xi_h(T)/a)} V_\Delta \left( \frac{2\pi T}{\Delta_0(T)}, \frac{\xi_s(T)}{\xi_h(T)} \right), \]  

\[ V_\Delta \left( \bar{T}, \alpha_h \right) = \left[ D(\bar{T}) \right]^{-1} \bar{T} \sum_{n=0}^\infty R(\hat{\omega}_n, \alpha_h), \]  

\[ D(\bar{T}) = \bar{T} \sum_{n=0}^\infty (\hat{\omega}_n^2 + 1)^{-3/2}, \]  

\[ R(z, \alpha_h) = \frac{1}{(z^2 + 1)^{3/2} (\alpha_h^2 - 1)} \left[ 1 + \frac{2z^2 - 1 - 2z^2 \alpha_h^2}{z^2 + 1} \right] L(z, \alpha_h), \]  

\[ L(z, \alpha_h) = \left\{ \begin{array}{ll} \frac{\sqrt{z^2 + 1}}{\sqrt{\alpha_h^2 - z^2 - 1}} \ln \left( \frac{\sqrt{z^2 + 1} + \sqrt{\alpha_h^2 - 1}}{\alpha_h} \right), & z^2 > \alpha_h^2 - 1 \\ \frac{\sqrt{z^2 + 1}}{\sqrt{\alpha_h^2 - z^2 - 1}} \arctan \left( \frac{\sqrt{\alpha_h^2 - z^2 - 1}}{\sqrt{z^2 + 1}} \right), & z^2 < \alpha_h^2 - 1 \end{array} \right. \]  

Note that the function \( L(z, \alpha_h) \) does not have singularity at \( z = \sqrt{\alpha_h^2 - 1} \) for \( \alpha_h > 1 \), contrary to what its shape may suggest. We see that the gap correction has the amplitude \( h_0^2/\Delta_0 \) and mostly depends on two dimensionless parameters: reduced temperature \( T/\Delta_0(T) \) and the ratio \( \alpha_h = \xi_s(T)/\xi_h(T) \). It also weakly depends on the ratio \( \xi_h/a \), which determines the logarithmic factor in the denominator of Eq. (36a).

Let us discuss asymptotic behavior of the reduced function \( V_\Delta(\bar{T}, \alpha_h) \) and the gap correction it gives. In the range \( \alpha_h \gg 1 \) corresponding to the scattering regime, the function \( R(z, \alpha_h) \) in Eq. (36d) behaves as \( R(z, \alpha_h) \approx \frac{\pi \sqrt{z^2 + 1}}{\alpha_h (z^2 + 1) \tau} \). This gives the following asymptotics of the function \( V_\Delta(\bar{T}, \alpha_h) \)

\[ V_\Delta \left( \bar{T}, \alpha_h \right) \approx \frac{\pi}{\alpha_h} V_\Delta(\bar{T}), \]  

\[ V_\Delta(\bar{T}) = \left[ D(\bar{T}) \right]^{-1} \bar{T} \sum_{n=0}^\infty \frac{\hat{\omega}_n^2}{(\hat{\omega}_n^2 + 1)^{3/2}}, \]  

where the limiting behaviors of the function \( V_\Delta(\bar{T}) \) are \( V_\Delta(0) = \pi/4 \) and \( V_\Delta(\bar{T}) \approx \pi^2 \bar{T}/[14 \zeta(3)] \) for \( \bar{T} \gg 1 \) with \( \zeta(3) \approx 1.202 \). Correspondingly, the correction to the gap in this regime simplifies to

\[ \tilde{\Delta}(T) \approx -\frac{\pi \xi_h h_0^2}{v_F \ln (\xi_h/a)} V_\Delta(\bar{T}) = -\frac{1}{\tau_m} V_\Delta(\bar{T}). \]  

This is a well-known result for the gap correction caused by the magnetic scattering [12].

In the opposite regime \( \alpha_h \to 0 \) corresponding to the vicinity of the magnetic transition, the function \( R(z, \alpha_h) \) has a logarithmic dependence on \( \alpha_h \)

\[ R(z, \alpha_h) = R_0(z) + R_1(z) \ln \left( \frac{1}{\alpha_h} \right), \]  

\[ R_0(z) = \frac{1}{(z^2 + 1)^3/2} \ln \left( \frac{2\sqrt{z^2 + 1}}{z^2 + 1} \right), \]  

\[ R_1(z) = \frac{2z^2 - 1}{(z^2 + 1)^{3/2}} \]  

meaning that \( V_\Delta(\bar{T}, \alpha_h) \) also logarithmically diverges for \( \alpha_h \to 0 \),

\[ V_\Delta \left( \bar{T}, \alpha_h \right) = A(\bar{T}) + B(\bar{T}) \ln \left( \frac{1}{\alpha_h} \right), \]  

\[ A(\bar{T}) = \left[ D(\bar{T}) \right]^{-1} \bar{T} \sum_{n=0}^\infty R_0(\hat{\omega}_n), \]  

\[ B(\bar{T}) = \left[ D(\bar{T}) \right]^{-1} \bar{T} \sum_{n=0}^\infty R_1(\hat{\omega}_n) \]  

with \( A(0) = 1, B(0) = 0 \). The plots of the coefficients \( A(\bar{T}) \) and \( B(\bar{T}) \) are shown in Fig. 2. The corresponding correction to the gap can be presented as

\[ \tilde{\Delta}(T) = -\frac{h_0^2 B(\bar{T})}{2\Delta_0} \left[ 1 + \frac{\ln (\xi_h/a)}{\ln (\xi_h/a)} \right]. \]  

Therefore, the absolute value of correction \( |\tilde{\Delta}| \) decreases when \( T \) approaches \( T_m \) if the ratio \( A(\bar{T})/B(\bar{T}) \) exceeds \( \ln (\xi_s/a) \), which always occurs at sufficiently low temperatures, see inset in Fig. 2. In this case the overall dependence of the correction on \( \xi_s \) is nonmonotonic and maximum suppression of the gap occurs at \( \xi_h \approx \xi_s \). The limiting value at \( T = T_m \), \( \Delta(T_m) = -h_0^2 B(T_m)/2\Delta_0 \), corresponds to the correction from a uniform exchange field equal to \( h_0 \). It vanishes for \( T_m \to 0 \) as \( \exp(-\Delta_0/T_m) \).
This is a monotonically-decreasing function with the integration noticeably overestimate the gap correction for rather more accurate asymptotic presented in Eq. (42) by dotted line and the scattering-regime dependence by dashed line and as discussed above. For zero temperature, we also show the scattering-regime asymptotics (dashed line) and more accurate asymptotics presented in Eq. (42) (dotted line).

At temperatures much smaller than \( T_c \), the summation over the Matsubara frequencies in Eq. (36b) can be transformed into integration leading to

\[
\Delta(0) = - \frac{\hbar^2}{2\Delta_{0}\ln(\xi_h/a)} V_{\Delta}(\frac{\xi_s}{\xi_h}) , \tag{41}
\]

where the reduced function \( V_{\Delta}(\alpha_h) \equiv V_{\Delta}(0,\alpha_h) \) is defined by the integral

\[
V_{\Delta}(\alpha_h) = \int_0^\infty R(z,\alpha_h) \, dz.
\]

This is a monotonically-decreasing function with the asymptotics

\[
V_{\Delta}(\alpha_h) \approx \begin{cases} 1 + \frac{\alpha_h^2}{2} (6\ln\alpha_h+1) & \text{for } \alpha_h \ll 1 \\ \frac{\pi^2}{4\alpha_h^2} - \frac{2\ln\alpha_h+1}{\alpha_h^2} & \text{for } \alpha_h \gg 1 \end{cases} . \tag{42}
\]

It also has the exact value \( V_{\Delta}(1) = \frac{\pi^2}{4} - \frac{3}{2} \). The large-\( \alpha_h \) asymptotics corresponds to the magnetic-scattering regime. Substituting the first leading term into Eq. (41) yields the known result for the gap correction at zero temperature \( \Delta(0) \approx -\pi/4\tau_m \), where \( \tau_m \) is given by Eq. (20).

Plots of the numerically evaluated function \( V_{\Delta}(\tilde{T},\alpha_h) \) are shown in Fig. 3 for several values of the reduced temperature \( \tilde{T} \). The function monotonically decreases with \( \alpha_h \) and increases with temperature. At zero temperature this function approaches a finite value for \( \alpha_h \to 0 \) while at finite temperatures it logarithmically diverges, as discussed above. For zero temperature, we also show the scattering-regime dependence by dashed line and more accurate asymptotic presented in Eq. (42) by dotted line. We can see that the scattering approximation noticeably overestimate the gap correction for rather large values of \( \alpha_h \). The finite value of the function for \( \alpha_h \to 0 \) at zero temperature is in an apparent contradiction with the known result that a uniform exchange field does not change the gap at zero temperature. This finite value is the consequence of small-distance behavior of the exchange-field correlation function for the two-dimensional case: it does not approach a constant for \( r \ll \xi_h \) but keeps growing logarithmically, see Eqs. (9) and (11). We note, however, that despite this small-\( \alpha_h \) saturation of the function \( V_{\Delta}(0,\alpha_h) \), the gap correction in Eq. (36a) does have a nonmonotonic dependence on \( \xi_h \) and vanishes in the limit \( \xi_h \to \infty \) at low temperatures because of the logarithmic factor in the denominator.

V. CORRECTION TO THE ELECTROMAGNETIC KERNEL AND LONDON PENETRATION DEPTH

In this section, we investigate the correction to the superconducting current response caused by the exchange interaction with correlated magnetic fluctuations. As in the case of the gap parameter, there are two different regimes depending on the relation between the magnetic correlation length \( \xi_h \) and superconducting coherence length \( \xi_s \). Our goal is to quantitatively describe the crossover between these two regimes. The case \( \xi_h < \xi_s \) corresponds to the well-studied magnetic-scattering regime. Influence of magnetic scattering on the electromagnetic kernel, which determines the London penetration depth, was investigated by Skalski et al.\[10\]
see also Ref.\textsuperscript{3} Recently, a very detailed investigation of this problem has been performed within the quasiclassical approach.\textsuperscript{20} Most studies, however, have been done for isotropic magnetic screening. The case of correlated magnetic fluctuation in the regime $k_F \xi_h \gg 1$ requires a proper accounting for the vertex correction to the kernel which is equivalent to accounting for the reverse scattering events in quasiclassical approach.\textsuperscript{2}

The superconducting current response

$$j_\alpha(q, \omega) = -Q_{\alpha\beta}(q, \omega) A_\beta(q, \omega)$$

(43)

is determined by the electromagnetic kernel $Q_{\alpha\beta}(q, \omega)$. In strongly type-II superconductors, the screening of magnetic field is determined by the local static kernel $Q_{\alpha\beta} \equiv Q_{\alpha\beta}(0, 0)$. The superfluid density $n_s$ introduced in the phenomenological London theory is related to $Q_{\alpha\beta}$ as $Q_{\alpha\beta} = e^2 n_s / c m_{\alpha\beta}$, where $m_{\alpha\beta}$ is the effective mass tensor. The London penetration depth components $\lambda_{\alpha}$ are related to the static uniform kernel as $Q_{\alpha\beta} = c / (4\pi \lambda_{\alpha}^2)$. In nonmagnetic superconductors the screening length $\lambda_{\alpha}$ is identical to this 'bare' length $\lambda_{\alpha}$ defined via the electromagnetic kernel. In magnetic superconductors, however, the screening length $\lambda_{\alpha}$ is reduced by the magnetic response of local moments as $\lambda_{\alpha} = \lambda_{\alpha} / \sqrt{\mu}$, where $\mu$ is the magnetic permeability in the magnetic-field direction.\textsuperscript{21,22}

Note that the exchange and magnetic response have opposite influences on the screening length: the former enlarges and the latter reduces it. In the following, we concentrate on the calculation of the bare London penetration depth.

In the Green's function formalism, the kernel can be evaluated as\textsuperscript{3}

$$Q_{\alpha\beta}(q, \omega) = \frac{e^2 n}{cm_{\alpha\beta}} + \frac{e^2}{2c} T \sum_{\omega_n} \int \frac{d^3 p}{(2\pi)^3} v_\alpha v_\beta 
× \text{Tr} \left[ \hat{G}(p, \omega_n) \hat{G}(p - q, \omega_n - \omega) \right],$$

(44)

where $n$ is total density and $v_\alpha = \partial \xi_p / \partial p_\alpha$ are the velocity components.\textsuperscript{7} In particular, for a free case

$$Q_{\alpha\beta}^{(0)} = \frac{2\pi e^2}{c} \nu \langle v_\alpha v_\beta \rangle T \sum_{\omega_n} \frac{\Delta_0^2}{(\omega_n^2 + \Delta_0^2)^{3/2}}$$

(45)

giving $Q_{\alpha\beta}^{(0)} = 2\pi e^2 \nu \langle v_\alpha v_\beta \rangle$ at zero temperature.

We first consider the scattering regime, $\xi_h \ll \xi_s$, within the quasiclassical approximation. The generalization of the isotropic-scattering calculations in Ref.\textsuperscript{3} for arbitrary scattering described in Appendix\textsuperscript{3} gives the following result for the correction to $\lambda_{\alpha}^2$ due to the magnetic scattering

$$\lambda_{\alpha}^2(T) = -\lambda_{\alpha}^{-2}(T) \left[ \frac{1}{\tau_m \Delta_0(T)} V_{\lambda,m} \left( \frac{2\pi T}{\Delta_0(T)} \right) \right],$$

(46)

with

$$V_{\lambda,m}(\hat{T}) = \frac{1}{D(\hat{T})} \int_{q=0}^\infty \frac{2\omega_n^2 - 1}{(1+\omega_n^2)^{3/2}} V_{\Delta}(\hat{T}) + \frac{3\omega_n^2 - 1}{(1+\omega_n^2)^3},$$

(47)

$$V_{\lambda,m,\tau}(\hat{T}) = \frac{1}{2D(\hat{T})} \int_{q=0}^\infty \frac{1 - \omega_n^2}{(1+\omega_n^2)^3},$$

(48)

where the functions $D(\hat{T})$ and $V_{\Delta}(\hat{T})$ are defined in Eqs. (36c) and (37b), respectively. Here $\tau_m$ is the magnetic-scattering lifetime, Eqs. (19) and (20), and $\tau_{m,\tau}$ is the corresponding transport time,

$$\frac{1}{2\tau_{m,\tau}} = \int \frac{\pi dS_{p'}}{(2\pi)^3 v_F} \left( 1 - \frac{\mathbf{v} \cdot \mathbf{v}'}{\langle \mathbf{v}^2 \rangle} \right) \langle |\mathbf{h}_{p-p'}|^2 \rangle.$$
where the first term in \( C_{\alpha\beta}(\omega) \) is the self-energy correction with \( \Sigma(p, \omega) \) given by Eq. (15) and the second term is the vertex correction with

\[
\delta \dot{v}_\beta = \sum_i \frac{d^3p'}{(2\pi)^3} \dot{a}_i \hat{G}_0(p') v'_i \hat{G}_0(p') \dot{a}_i \left\langle \vert \hat{h}_{p-p'} \vert^2 \right\rangle .
\]

(52)

Figure 4 shows the diagrammatic presentation of these equations. We split the vertex correction into two contributions

\[
\delta \dot{v}_\beta = v_\beta \hat{\Gamma}_p + \delta \dot{v}_\beta,
\]

\[
\hat{\Gamma}_p = \sum_i \frac{d^3p'}{(2\pi)^3} \dot{a}_i \hat{G}_0(p') \hat{G}_0(p') \dot{a}_i \left\langle \vert \hat{h}_{p-p'} \vert^2 \right\rangle ,
\]

\[
\delta \dot{v}_\beta = \sum_i \frac{d^3p'}{(2\pi)^3} \dot{a}_i \hat{G}_0(p') \left( v'_\beta - v_\beta \right) \hat{G}_0(p') \dot{a}_i \times \left\langle \vert \hat{h}_{p-p'} \vert^2 \right\rangle .
\]

The second contribution \( \delta \dot{v}_\beta \) is proportional to the transport magnetic scattering rate and in our situation is typically smaller than the first one. We therefore focus on the calculation of the first contribution.

Using the relations

\[
\hat{G}_0 \hat{G}_0 = i \frac{\partial \hat{G}_0}{\partial \omega} ,
\]

\[
\hat{\Gamma} = i \frac{\partial \hat{G}_0}{\partial p} ,
\]

(53a)

(53b)

where the second relation is usually called Ward identity, we can present \( C_{\alpha\beta}(\omega) \) as

\[
C_{\alpha\beta}(\omega) = - C_{\alpha\beta}(\omega) + C_{\text{tr}}^{\alpha\beta}(\omega) ,
\]

\[
C_{\alpha\beta}(\omega) = i \frac{\partial}{\partial \omega} \int \frac{d^3p}{(2\pi)^3} v_\alpha v_\beta \text{Tr} \left[ \hat{G}_0(p, \omega) \Sigma(p, \omega) \hat{G}_0(p, \omega) \right] ,
\]

(54)

\[
C_{\text{tr}}^{\alpha\beta}(\omega) = \int \frac{d^3p}{(2\pi)^3} v_\alpha \text{Tr} \left[ \hat{G}_0(p, \omega) \delta \dot{v}_\beta \hat{G}_0(p, \omega) \right] .
\]

The term \( C_{\text{tr}}^{\alpha\beta}(\omega) \) corresponds to contribution in Eq. (40) proportional to the transport magnetic scattering rate \( 1/\tau_m \). As discussed above, in our case this term is typically small and does not increase when the temperature approaches the magnetic transition. That is why we will neglect this term in the following consideration. As the term \( C_{\alpha\beta}^{\text{tr}}(\omega) \) is proportional to a full derivative with respect to \( \omega \), it vanishes at zero temperature. To evaluate this term, we explicitly compute the trace inside the integral as

\[
\text{Tr} \left[ \hat{G}_0(p, \omega) \Sigma(p, \omega) \hat{G}_0(p, \omega) \right] = 4 \left( G_{00}^2 + G_{0z}^2 + G_{yz}^2 \right) \Sigma_{00} + 2G_{00}G_{0z} \Sigma_{0z} + 2G_{00}G_{yy} \Sigma_{yy} ,
\]

where \( \Sigma_{00} \) and \( \Sigma_{0z} \) are given by Eqs. (24) and (28), respectively, and \( \Sigma_{yy} = - (\Delta/\omega) \Sigma_{00} \). Substituting these results into Eq. (54), we transform \( C_{\alpha\beta}^{m, \text{tr}}(\omega) \) to

\[
C_{\alpha\beta}^{m, \text{tr}}(\omega) = \frac{\rho h_F^2}{\pi} \nu \left\langle v_\alpha v_\beta \right\rangle \times \frac{\partial}{\partial \omega} \omega \left( \omega^2 + \Delta_0^2 \right)^{3/2} \text{Re} \int_{-\infty}^{\infty} dz \frac{-\omega^2 + 3\Delta_0^2}{(z^2 + 1)^2} W(z, g) ,
\]

where \( z = \xi/\sqrt{\omega^2 + \Delta_0^2} \). The parameter \( g \equiv g_n \) and the function \( W(z, g) \) are defined in Eqs. (25) and (26), respectively. Computation of the \( z \) integral yields the result...
C_{\alpha \beta}^m(\omega) = -4C_h \hbar^2 \nu (\nu \nu) \frac{\partial}{\partial \omega} \left\{ \frac{\omega \Delta_0^2}{(\omega^2 + \Delta_0^2)^{3/2}} \left[ 1 - \frac{6 - g^2}{\sqrt{4 - g^2}} \ln \left( \frac{2 + \sqrt{4 - g^2}}{g} \right) \right] \right\}.  

Therefore, the corresponding correction to the kernel, Eq. (50), is

$$\delta Q_{\alpha \beta}^\Delta = -2C_h \hbar^2 \nu (\nu \nu) T \sum_{\omega_n} \frac{\partial}{\partial \omega_n} \left\{ \frac{\omega_n \Delta_0^2}{(\omega_n^2 + \Delta_0^2)^{3/2}} \left[ 1 - \frac{6 - g^2}{\sqrt{4 - g^2}} \ln \left( \frac{2 + \sqrt{4 - g^2}}{g} \right) \right] \right\}.  \tag{56}$$

This result gives correction at the fixed gap parameter. The full correction also contains the contribution due to the shift of $\Delta$, $\delta Q_{\alpha \beta}^\Delta = \Delta \delta Q_{\alpha \beta}^{(0)} / d \Delta$, where $\Delta$ is given by Eq. (36a). Using the same reduced variables as in Eq. (50), we rewrite the corresponding correction to $\lambda^{-2} \propto Q_{\alpha \alpha}$ in the reduced form suitable for numerical evaluation

$$\lambda^{-2}(T) = -\lambda^{-2}(T) \frac{\hbar^2}{2 \Delta_0^2 \ln (\xi_h / a)} V_Q \left( \frac{2 \pi T}{\Delta_0}, \frac{\xi_s}{\xi_h} \right) \tag{57a}$$

with

$$V_Q(T, \alpha_h) = \left[ D(T) \right]^{-1} T \sum_{n=0}^{\infty} \left[ K_Q(\tilde{\omega}_n) V_\Delta(T, \alpha_h) + R_Q(\tilde{\omega}_n, \alpha_h) \right],  \tag{57b}$$

$$K_Q(z) = -\frac{\partial}{\partial z} \left[ \frac{z}{(z^2 + 1)^{3/2}} \right], \tag{57c}$$

$$R_Q(z, \alpha_h) = -\frac{\partial}{\partial z} \left[ \frac{z}{(z^2 + 1)^{3/2}} \frac{1 - \left( 3 - 2\alpha_h^2 \right) L(z, \alpha_h)}{(z^2 + 1)^{3/2}} \right], \tag{57d}$$

where the first term in the curly brackets in Eq. (57b) is due to the gap correction, the function $V_\Delta(T, \alpha_h)$ is defined in Eq. (36b), and the function $L(z, \alpha_h)$ in the last definition is defined in Eq. (36c). For brevity in Eq. (57a), we omitted the $T$ dependences of $\Delta_0(T)$, $\xi_s(T)$, and $\xi_h(T)$. Plots of the function $V_Q(T, \alpha_h)$ versus $\alpha_h$ for different values of $T$ are shown in Fig. 5. As the function $V_\Delta(T, \alpha_h)$ shown in Fig. 5 this function also monotonically decreases with increasing of both $T$ and $\alpha_h$. The essential difference is that the function $V_Q(T, \alpha_h)$ vanishes for $T \to 0$ while the function $V_\Delta(T, \alpha_h)$ approaches the finite limit.

The large-$\alpha_h$ asymptotics of the function $V_Q(T, \alpha_h)$ is $V_Q(T, \alpha_h) \approx T \Delta_0 \alpha_h V_{\lambda, m}(T)$, where the function $V_{\lambda, m}(T)$ is defined in Eq. (47). These asymptotics are also shown in Fig. 5 by dashed lines. Noting also the relation $\pi h^2 / (2\alpha_h \Delta_0 \ln (\xi_h / a)) = 1 / \tau_{\lambda}$, we see that in the limit $\alpha_h \gg 1$ the above result reproduces the correction in Eq. (46) for the scattering regime.

At small $\alpha_h$ corresponding to the proximity of the magnetic transition, the function $R_Q(z, \alpha_h)$ has logarithmic dependence on $\alpha_h$,

$$R_Q(z, \alpha_h) \approx R_Q(0)(z) + R_Q(1)(z) \ln \left( \frac{1}{\alpha_h} \right),$$

$$R_Q(0)(z) = \frac{\partial}{\partial z} \left[ \frac{z - 3 \ln (2\sqrt{z^2 + 1})}{(z^2 + 1)^{3/2}} \right],$$

$$R_Q(1)(z) = -\frac{\partial}{\partial z} \frac{3z}{(z^2 + 1)^{3/2}}.$$

The function $V_\Delta(T, \alpha_h)$ describing the gap contribution also has logarithmic dependence on $\alpha_h$, Eq. (39). Correspondingly, the function $V_Q(T, \alpha_h)$ also logarithmically diverges with $\alpha_h \to 0$,

$$V_Q(T, \alpha_h) = A_Q(T) + B_Q(T) \ln \left( \frac{1}{\alpha_h} \right), \tag{58a}$$

with

$$A_Q(T) = \left[ D(T) \right]^{-1} T \sum_{n=0}^{\infty} \left[ K_Q(\tilde{\omega}_n) A(T) + R_Q(0)(\tilde{\omega}_n) \right], \tag{58b}$$

$$B_Q(T) = \left[ D(T) \right]^{-1} T \sum_{n=0}^{\infty} \left[ K_Q(\tilde{\omega}_n) B(T) + R_Q(1)(\tilde{\omega}_n) \right], \tag{58c}$$

where the coefficients $A(T)$ and $B(T)$ are defined in Eq. (39). The small-$\alpha_h$ asymptotics are plotted in Fig. 6 with dotted lines and plots of the coefficients $A_Q(T)$ and $B_Q(T)$ and their ratio are presented in Fig. 6. Note that the coefficient $A_Q(T)$ becomes negative for $T < 0.683$. Even though the small-$\alpha_h$ behavior in Eq. (39a) looks similar to the behavior of the gap in Eq. (39), the essential difference is that both coefficients $A_Q(T)$ and $B_Q(T)$ vanish at $T = 0$.

Similar to Eq. (40), we can present the correction in Eq. (57a) in the limit $\xi_h \gg \xi_s$ as

$$\lambda^{-2} \lambda = -\lambda^{-2} \frac{2\hbar^2 B_Q(T)}{2 \Delta_0^2} \left[ 1 - \frac{\ln \left( \frac{\xi_s}{\xi_h} \right) - A_Q(T) / B_Q(T)}{\ln (\xi_h / a)} \right]. \tag{59}$$
VI. DISCUSSION

In summary, we evaluated the corrections to the gap, Eq. (36a), and superfluid density, Eq. (57a), caused by the exchange interaction with quasi-two-dimensional magnetic fluctuations in materials composed of superconducting and local-moment layers. Growth of the correlation length near the magnetic transition enhances spin-flip scattering leading to increasing suppression of superconducting parameters. This suppression significantly weakens when the magnetic correlation length exceeds the coherence length. In addition to dependence on the correlation length $\xi_{h}(T)$, the corrections have also direct regular dependence on the ratio $T/\Delta(T)$. Moreover, as one can see from Figs. 3 and 5, in the paramagnetic state these dependences are opposite. While, in the immediate vicinity of the magnetic transition the growth of $\xi_{h}(T)$ dominates, in a wider range, the overall temperature dependence is determined by the interplay between both sources. To generate the parameter’s temperature dependences for real materials from the derived general formulas, one need to specify the temperature dependent gap, coherence length, and magnetic correlation length, as well as the strength of the exchange field.

Even though the consideration of this paper has been mostly motivated by physics of RbEuFe$_{4}$As$_{4}$, at present, there are too many uncertainties in the parameters of this material to make a reliable quantitative predictions. Therefore, we limit ourselves with showing expected qualitative behavior using representative parameters and illustrating general trends. Figure 7(left) shows the temperature dependences of the gap and $\lambda^{-2}$ for the parameters very roughly corresponding to RbEuFe$_{4}$As$_{4}$. Namely, we assume (i) the the Ginzburg-Landau coherence length $\xi_{GL}^{c0}$ = 1.46nm, following from the linear slope of the c-axis upper critical field $\xi_{c0}$ = 21,22, (ii) the BCS value of the zero-temperature gap, $\Delta_{0}(0)$ = 1.76$T_{c}$ ≈ 5.6meV, (iii) the BCS temperature dependences for all unperturbed superconducting parameters, (iv) the amplitude of the exchange field $h_{0} = 0.6T_{c}$, (v) the magnetic transition at $t_{m} = T_{m}/T_{c}$ = 0.4, and (vi) Berezinskii-Kosterlitz-Thouless (BKT) shape for the magnetic correlation length, $\xi_{h}(T) = a \exp[b\sqrt{T_{m}/(T-T_{m})}]$, where $a = 0.39$ nm is the distance between the neighboring Eu$^{2+}$ moments and we take the value $b = 0.5$ for nonuniversal numerical constant. For these parameters, $\xi_{c}(T_{m}) = 6.6a$ and the ‘scattering-to-smooth’ crossover is nominally located at $t_{cr}$ ≈ 0.43. We see, however, that above this temperature the behavior is not well described by the scattering-regime asymptotics shown by the dashed lines. This is related to the broad range of the crossover. Consequently, for selected parameters, the gap does not display a nonmonotonic behavior, expected from the anal-

The ratio $A_{Q}(\tilde{T})/B_{Q}(\tilde{T})$ is of the order unity in the whole temperature range and becomes negative for $\tilde{T} < 0.683$, see inset in Fig. 5, meaning that the nominator $\ln(\xi_{c}/a) - A_{Q}(\tilde{T})/B_{Q}(\tilde{T})$ is always positive. As a consequence, the correction to the superfluid density monotonically increases when temperature approaches $T_{m}$. This is different from the behavior of the gap correction, Eq. (36a), which becomes nonmonotonic at small temperatures. The maximum suppression of $\lambda^{-2}$ for $\xi_{h} \rightarrow \infty$, $\lambda_{\alpha,\max}^{-2} = -(\hbar v_{f}^{2} / 2\Delta(0) \xi_{h}^{2} / 2\Delta(0) ) B_{Q}(2\pi T_{m} / \Delta_{0})$, corresponds to the correction from a uniform exchange field equal to $h_{0}$. 

FIG. 5. Plots of the function $V_{Q}(\tilde{T}, \alpha_{h})$ in Eq. (57b) which determines the correction to the electromagnetic kernel and London penetration depth in Eq. (57a). The dashed lines show large-$\alpha_{h}$ asymptotics, $V_{Q}(\tilde{T}, \alpha_{h}) \propto 1/\alpha_{h}$, corresponding to the scattering regime. The dotted lines show small-$\alpha_{h}$ asymptotics, $V_{Q}(\tilde{T}, \alpha_{h}) \propto \ln(1/\alpha_{h})$.

FIG. 6. Temperature dependence of the coefficients $A_{Q}(\tilde{T})$ and $B_{Q}(\tilde{T})$ defined by Eqs. (58b) and (58c), respectively, which determine the small-$\alpha_{h}$ asymptotics of the function $V_{Q}(\tilde{T}, \alpha_{h})$, Eq. (58a). The inset shows the temperature dependence of their ratio. The coefficient $A_{Q}(\tilde{T})$ changes sign at $T = 0.683$. 

The plot of $A_{Q}(\tilde{T})/B_{Q}(\tilde{T})$ is of the order unity in the whole temperature range and becomes negative for $\tilde{T} < 0.683$, see inset in Fig. 5, meaning that the nominator $\ln(\xi_{c}/a) - A_{Q}(\tilde{T})/B_{Q}(\tilde{T})$ is always positive. As a consequence, the correction to the superfluid density monotonically increases when temperature approaches $T_{m}$. This is different from the behavior of the gap correction, Eq. (36a), which becomes nonmonotonic at small temperatures. The maximum suppression of $\lambda^{-2}$ for $\xi_{h} \rightarrow \infty$, $\lambda_{\alpha,\max}^{-2} = -(\hbar v_{f}^{2} / 2\Delta(0) \xi_{h}^{2} / 2\Delta(0) ) B_{Q}(2\pi T_{m} / \Delta_{0})$, corresponds to the correction from a uniform exchange field equal to $h_{0}$. 

FIG. 6. Temperature dependence of the coefficients $A_{Q}(\tilde{T})$ and $B_{Q}(\tilde{T})$ defined by Eqs. (58b) and (58c), respectively, which determine the small-$\alpha_{h}$ asymptotics of the function $V_{Q}(\tilde{T}, \alpha_{h})$, Eq. (58a). The inset shows the temperature dependence of their ratio. The coefficient $A_{Q}(\tilde{T})$ changes sign at $T = 0.683$. 

The ratio $A_{Q}(\tilde{T})/B_{Q}(\tilde{T})$ is of the order unity in the whole temperature range and becomes negative for $\tilde{T} < 0.683$, see inset in Fig. 5, meaning that the nominator $\ln(\xi_{c}/a) - A_{Q}(\tilde{T})/B_{Q}(\tilde{T})$ is always positive. As a consequence, the correction to the superfluid density monotonically increases when temperature approaches $T_{m}$. This is different from the behavior of the gap correction, Eq. (36a), which becomes nonmonotonic at small temperatures. The maximum suppression of $\lambda^{-2}$ for $\xi_{h} \rightarrow \infty$, $\lambda_{\alpha,\max}^{-2} = -(\hbar v_{f}^{2} / 2\Delta(0) \xi_{h}^{2} / 2\Delta(0) ) B_{Q}(2\pi T_{m} / \Delta_{0})$, corresponds to the correction from a uniform exchange field equal to $h_{0}$.
analysis of asymptotics. In fact, due to the interplay between two competing temperature dependences, both corrections are almost temperature independent in the range $0.42 < t < 0.47$. Nevertheless, we see that, according to the general predictions, $\Delta(T)$ somewhat increases when $T$ approaches $T_m$, while $[\lambda(T)]^{-2}$ shows a noticeable drop. For illustrative purposes, we show in Fig. 7(right) the plots of $\Delta(T)$ and $[\lambda(T)]^{-2}$ for the same parameters as in the previous figure except for larger coherence length, $\xi_s^{GL} = 10a \approx 3.9\text{nm}$. In this case $\xi_s(T_m) = 17.6a$ and the crossover nominally takes place much closer to $t_m$, at $t_c \approx 0.41$. In this case the behavior at $t > 0.43 - 0.44$ is already fairly well described by the scattering asymptotics. The gap in this case does have a nonmonotonic temperature dependence.

Clearly, the plots in Fig. 7(left) do not literally describe the behavior of RbEuFe$_4$As$_4$, and serve only as a qualitative illustration. This material has several additional features that influence the behavior of the parameters but substantially complicate an accurate analysis. Firstly, the assumed two-dimensional behavior always breaks down sufficiently close to the transition and the dimensional crossover to the three-dimensional regime takes place. In this 3D regime the correlations between the different magnetic layers emerge meaning that the assumption for two-dimensional scattering does not work any more. In addition, the magnetic correlation length does not follow the BKT temperature dependence assumed in Fig. [7]. Secondly, due to spatial separation between the magnetic and conducting layers, we expect a significant nonlocality of the exchange interaction, see Eq. [6], ranging at least 2–3 lattice spacing. Consideration of this manuscript assumes that the magnetic correlation length exceeds this nonlocality range. This assumption is only justified close to the magnetic transition. The nonlocality significantly reduces the exchange corrections at higher temperatures, when $\xi_s$ drops below the nonlocality range. Finally, our single-band consideration does not take into account a complicated multiple-band structure of RbEuFe$_4$As$_4$.

In this paper, we developed a general theoretical framework for the analysis of the influence of correlated mag-
netic fluctuations on superconducting parameters. We focus on the behavior of the gap and superfluid density for the in-plane current direction, but the consideration can be directly extended to other thermodynamic and transport properties. For some properties, however, such as specific heat and magnetization, a reliable separation of the superconducting contribution from the magnetic background in experiment is challenging. This makes a theoretical analysis somewhat academic. Our result can be straightforwardly generalized to the case of a large exchange field leading to a strong suppression of superconductivity. Such generalization requires the development of a self-consistent scheme similar to the AG theory. For the problem considered here, this is a formidable theoretical task.

Appendix A: Calculation of the integral for the gap correction

In this appendix we briefly describe calculation of the integral in Eq. (33) leading to result in Eq. (34). Substituting the function $W(z, g)$ defined in Eq. (26) into Eq. (33), we present

$$I = \frac{4\pi}{\omega} \frac{\Delta_0}{(\omega^2 + 4\omega_n^2)} \left[ T_1(g) + \frac{4\omega_n^2}{\omega_n^2 + \Delta_0^2} T_2(g) \right],$$

(A1)

where

$$T_1(g) = \mathrm{Re} \left[ \int_{-\infty}^{\infty} dz \frac{2}{(iz + 1)^2 - g^2} \ln \left( \frac{iz + 1 + \sqrt{(iz + 1)^2 - g^2}}{g} \right) \right],$$

$$T_2(g) = \mathrm{Re} \left[ \int_{-\infty}^{\infty} dz \frac{2}{(z^2 + 1)^2 - g^2} \ln \left( \frac{iz + 1 + \sqrt{(iz + 1)^2 - g^2}}{g} \right) \right].$$

The integral for $T_1(g)$ has a pole at $z = -i$ and branches at the imaginary axis terminating at $z_{\pm} = i(1 \pm g)$. Deforming the integration contour into the complex plane, we reduce it to the integral along the square root-branch $z = ix, 1 + g < x < \infty$,

$$T_1(g) = -2\pi \int_{1+g}^{\infty} dx \frac{2}{(x + 1)^2 - g^2} \ln \left( \frac{2 + \sqrt{4 - g^2}}{g} \right).$$

The integral for $T_1(g)$, has the same square-root branches and the poles at $z = \pm i$. Consequently, we split the integral into contribution from the pole at $z = i$ and square root branch $z = ix$, $1 + g < x < \infty$ which yeilds

$$T_2(g) = -\pi \frac{\pi^2}{2g} - \pi \frac{\pi^2}{2g} + 4\pi \int_{1+g}^{\infty} dx \frac{1}{(x^2 - 1)^2 - g^2} \ln \left( \frac{2 + \sqrt{4 - g^2}}{g} \right).$$

Substituting the above results into Eq. (A1), we arrive to Eq. (34).

Appendix B: Magnetic-scattering correction to the London penetration depth using quasiclassical approach

The London penetration depth $\lambda$ in the presence of isotropic potential and magnetic scattering has been investigated within the quasiclassical approach in Ref. [32]. Here we derive a general equation for $\lambda$ for arbitrary magnetic scattering having in mind application to the case of correlated magnetic fluctuations. The Eilenberger equations for the quasiclassical Green’s functions, $f(p, r)$, $f^\dagger(p, r)$, and $g(p, r)$ for arbitrary scattering are [32]

$$v\Pi f = \Delta_{g} - 2\omega_n f$$

$$+ g \langle [W(p, p') - W_m(p, p')] f \rangle'$$

$$- f \langle [W(p, p') + W_m(p, p')] g \rangle'$$

$$+ g \langle [W(p', p') - W_m(p', p')] f' \rangle'$$

$$- f \langle [W(p', p') + W_m(p', p')] g' \rangle'$$

(B1a)

$$+ g \langle [W(p', p') - W_m(p', p')] f \rangle'$$

$$- f \langle [W(p', p') + W_m(p', p')] g \rangle'$$

(B1b)

where we used shortened notations $f \equiv f(p, r)$, $f' \equiv f(p', r)$, $\Pi f \equiv (\nabla + 2\pi i A / \phi_0) f$, $(A(p'))' \equiv \int_{\mathbb{R}^3} d^3 p' \rho(p') A(p')$, and $\rho(p) = [(2\pi)^3 \pi v_F(p)]^{-1}$. Further, $W(p, p')$ and $W_m(p, p')$ are the probabilities of potential and magnetic scattering defining the corresponding scattering times as

$$1/\tau = \langle W(p, p') \rangle', \quad 1/\tau_m = \langle W_m(p, p') \rangle'.$$

For the model considered in this paper $W_m(p, p') = 2\pi \nu \langle |\tilde{h}_{p-p'}|^2 \rangle$. The above equations have to be supplemented with the normalization condition $g^2 = 1 - f f'$,
the gap equation
\[ \frac{\Delta}{2\pi T} \ln \frac{T_0}{T} = \sum_{\omega_n > 0} \left( \frac{\Delta}{\omega} - (f) \right), \]  
(B2)
and formula for the current
\[ j = 4\pi e\nu T \text{Im} \sum_{\omega_n > 0} \langle v q \rangle. \]  
(B3)

Our goal is to derive the response to weak supercurrents. In linear order, weak supercurrents do not modify the gap absolute value but only add the same phase \( \theta(r) \) to \( \Delta \) and \( f \) and the opposite phase to \( f^\dagger \). Therefore, the linear-order solutions have the form,
\[ \Delta = \Delta_0 e^{i\theta}, \quad f = (f_0 + f_1)e^{i\theta}, \]
\[ f^\dagger = (f_0 + f_1)e^{-i\theta}, \quad g = g_0 + g_1, \]
where only the phase \( \theta \) has coordinate dependence, while \( f_1, f_1^\dagger, g_1 \) are uniform meaning that \( \Pi f = iPf \) and \( \Pi^\dagger f^\dagger = -iPf^\dagger \) with \( P = \nabla \theta + 2\pi A/\phi_0 \). Equations for the linear corrections are
\[ 2\Delta_0 g_1 - 2\omega_n f_1 + \frac{g_1(p)}{\tau_-} f_0 - \frac{f_1(p)}{\tau_+} g_0 + \frac{1}{\tau_+} f_0 \]
\[ + g_0 \left[ \langle W(p, p') - W_m(p, p') \rangle f_1(p') \right]', \]
\[ - f_0 \left[ \langle W(p, p') + W_m(p, p') \rangle g_1(p') \right]' = iv_\alpha \Omega_0 f_0, \]  
(B4)
\[ g_0 g_1 = -f_0 f_1 \]  
(B5)
with \( \frac{1}{\tau_\pm} = \frac{1}{\tau} \pm \frac{1}{\tau_m} \). The remaining averages in the first equation account for the reverse scattering events. These averages vanish for the case of isotropic scattering. We assume that the solutions are proportional to \( v_\alpha P_\alpha \) and define the corresponding averages as
\[ \langle W(p, p')v_\alpha' \rangle' = \frac{1}{\tau_\alpha} v_\alpha, \quad \langle W_m(p, p')v_\alpha' \rangle' = \frac{1}{\tau_m} v_\alpha, \]
giving
\[ \frac{1}{\tau_\alpha} = \langle \langle W(p, p')v_\alpha v_\alpha' \rangle' \rangle', \quad \frac{1}{\tau_m} = \langle \langle W_m(p, p')v_\alpha v_\alpha' \rangle' \rangle'. \]  
(B6)
These quantities determine the corresponding transport times in a standard way, \( 1/\tau_\alpha = 1/\tau - 1/\tau_\sigma \) and \( 1/\tau_m = 1/\tau_m - 1/\tau_\sigma \). In the case of correlated magnetic fluctuation which we consider in this paper, the transport rate is much smaller than the total scattering rate. The averaging in Eq. (B6) can now be performed as,
\[ \langle W(p, p')f_1(p') \rangle' = \frac{f_1(p)}{\tau_\pm}. \]
with \( 1/\tau_\pm = 1/\tau \pm 1/\tau_m \). This allows us to rewrite Eq. (B4) as
\[ 2\Delta_0 g_1 - 2\omega_n f_1 + \frac{g_1}{\tau_-} f_0 + \frac{f_1}{\tau_-} g_0 - \frac{f_1}{\tau_+} g_0 = iv_\alpha \Omega_0 f_0, \]  
(B7)
Substituting \( g_1 = -f_0 f_1/g_0 \) from Eq. (B5), we obtain the solutions
\[ f_1 = -\frac{iv_\alpha f_0 P_\alpha}{2\omega_n + 2\Delta_0 f_0 g_0 \left( \frac{1}{\tau_-} - \frac{1}{\tau_+} \right) + g_0 \left( \frac{1}{\tau_-} - \frac{1}{\tau_+} \right)}, \]  
(B8)
\[ g_1 = \frac{f_0^2}{g_0} \frac{iv_\alpha P_\alpha}{2\omega_n + 2\Delta_0 f_0 g_0 \left( \frac{1}{\tau_-} - \frac{1}{\tau_+} \right) + g_0 \left( \frac{1}{\tau_-} - \frac{1}{\tau_+} \right)}. \]  
(B9)
We can rewrite the scattering-rate differences here in terms of scattering and transport times as
\[ \frac{1}{\tau_-} - \frac{1}{\tau_+} = \frac{1}{\tau_{tr}} - \frac{2}{\tau_m} + \frac{1}{\tau_{tr}}, \]
\[ \frac{1}{\tau_+} - \frac{1}{\tau_-} = \frac{1}{\tau_{tr}} + \frac{2}{\tau_m} - \frac{1}{\tau_{tr}}. \]
We use a standard parametrization for the unperturbed Green’s function components
\[ f_0 = \frac{1}{\sqrt{1 + u^2}}, \quad g_0 = \frac{u}{\sqrt{1 + u^2}}. \]
The parameter \( u \) obeys the Abrikosov-Gor’kov equation
\[ u \left( 1 - \frac{1}{\tau_m \Delta \sqrt{1 + u^2}} \right) = \frac{\omega_n}{\Delta}. \]  
(B10)
and determines the gap via equation
\[ \Delta \ln \frac{T_0}{T} = 2\pi T \sum_{\omega_n > 0} \left( \frac{\Delta}{\omega_n} - \frac{1}{\sqrt{1 + u^2}} \right). \]  
(B11)
We proceed with the derivation of the current response using Eq. (B3). Rewriting \( g_1 \) in Eq. (B9) in terms of the parameter \( u \)
\[ g_1 = \frac{iv_\alpha P_\alpha}{(1 + u^2) \left( 2\Delta \sqrt{1 + u^2} + \frac{1}{\tau_+} \right) - \frac{2}{\tau_m}}, \]
and substituting it into Eq. (B3), we obtain the linear current response as
\[ j_\alpha = 4\pi e\nu T \sum_{\omega_n > 0} \frac{\langle v_\alpha'^2 \rangle}{(1 + u^2) \left( 2\Delta \sqrt{1 + u^2} + \frac{1}{\tau_+} \right) - \frac{2}{\tau_m}} P_\alpha. \]  
(B12)
Using the definition \( 4\pi j_\alpha/c = -\lambda_\alpha^2 A_\alpha \) and \( P_\alpha = 2\pi A_\alpha/\phi_0 \), we finally obtain the result for \( \lambda_\alpha^2 \)
\[ \lambda_\alpha^2 = \frac{16\pi^2 e\nu \langle v_\alpha'^2 \rangle T}{c\phi_0} \sum_{\omega_n > 0} \frac{1}{(1 + u^2) \left( \Delta \sqrt{1 + u^2} + \frac{1}{\tau_+} \right) - \frac{1}{\tau_m}}. \]  
(B13)
This result can be used for self-consistent evaluation of the London penetration depth of arbitrary scattering. Note that it is different from the similar result in Ref.12 by the sign in front of \( \frac{1}{\tau_m} \) in the denominator.
a. Small-scattering-rate expansion

For comparison with the results in the main text, we derive small correction to $\lambda_{\alpha}^{-2}$ in the case of weak scattering. Expanding the parameter $u$ in Eq. (B10), $u = \frac{\omega_n}{\lambda} + u_m$, we obtain

$$u_m \approx \frac{\omega_n}{\tau_m \Delta \sqrt{\omega_n^2 + \Delta^2}}.$$  

Substituting this expansion into the gap equation, Eq. (B11), we derive the correction to the gap, $\Delta = \Delta_0 + \Delta$,

$$\Delta = -\frac{2\pi T}{\tau_m \Delta_0 \omega_n > 0 \frac{\omega_n^2}{(\Delta_0^2 + \Delta_0^2)^{3/2}}} \left[ 2\pi T \sum_{\omega_n > 0} \frac{1}{(\Delta_0^2 + \Delta_0^2)^{3/2}} \right]^{-1}.$$  

(B14)

In the reduced form, this correction is identical to Eq. (38).

To derive the correction to $\lambda_{\alpha}^{-2}$, we expand the fraction in Eq. (B13)

$$\frac{1}{1 + u^2 \left( \sum_{\omega_n > 0} \frac{\omega_n^2}{(\Delta_0^2 + \Delta_0^2)^{3/2}} \left[ 2\pi T \sum_{\omega_n > 0} \frac{1}{(\Delta_0^2 + \Delta_0^2)^{3/2}} \right]^{-1} \right)} \approx \frac{\Delta^2}{(\Delta_0^2 + \Delta_0^2)^{3/2}}$$

and also separate the contribution from the gap correction

$$\frac{\Delta^2}{(\Delta_0^2 + \Delta_0^2)^{3/2}} \approx \frac{\Delta_0^2}{(\Delta_0^2 + \Delta_0^2)^{3/2}} + \Delta_0 \frac{(2\omega_n^2 - \Delta_0^2)}{(\Delta_0^2 + \Delta_0^2)^{3/2}}.$$  

This gives the correction to $\lambda_{\alpha}^{-2}$,

$$\lambda_{\alpha}^{-2} \approx \lambda_{0\alpha}^{-2} + \lambda_{1\alpha}^{-2},$$

$$\lambda_{0\alpha}^{-2} = \frac{16\pi^4 \nu^2}{\phi_0^2} \tau \sum_{\omega_n > 0} \frac{\Delta_0^2}{(\Delta_0^2 + \Delta_0^2)^{3/2}},$$

$$\lambda_{1\alpha}^{-2} = \frac{16\pi^4 \nu^2}{\phi_0^2} \tau \sum_{\omega_n > 0} \left[ \frac{\Delta_0 \Delta (2\omega_n^2 - \Delta_0^2)}{(\Delta_0^2 + \Delta_0^2)^{5/2}} - \frac{\Delta_0^2 (3\omega_n^2 - \Delta_0^2)}{\tau_m (\Delta_0^2 + \Delta_0^2)^3} + \frac{\Delta_0^2 (\omega_n^2 - \Delta_0^2)}{2\tau_m (\Delta_0^2 + \Delta_0^2)^3} - \frac{\Delta_0^2}{2\tau_m (\Delta_0^2 + \Delta_0^2)^3} \right].$$  

(B15)

We see that, in contrast to the potential scattering, which only influences the London penetration depth via the transport time, the magnetic-scattering contribution to $\lambda_{\alpha}^{-2}$ also has contributions proportional to the total scattering rate $1/\tau_m$, both direct and via the gap correction. This pair-breaking contribution, however, vanishes at zero temperature. For numerical convenience, we can rewrite the correction in the following reduced form

$$\lambda_{\alpha}^{-2}(T) = -\lambda_{0\alpha}^{-2}(T) \left[ \frac{1}{\tau_m \Delta_0} V_{\lambda\alpha} \left( \frac{2\pi T}{\Delta_0} \right) + \frac{1}{\tau_{\text{tr}} \Delta_0} V_{\lambda\alpha}^{\text{tr}} \left( \frac{2\pi T}{\Delta_0} \right) \right],$$  

(B16)

with

$$V_{\lambda\alpha}(T) = \left[ D(T) \right]^{-1} \sum_{n=0}^{\infty} \frac{2\omega_n^2 - 1}{(1 + \omega_n^2)^{3/2}} V_{\Delta} \left( T \right) + \frac{3\omega_n^2 - 1}{(1 + \omega_n^2)^3},$$

$$V_{\lambda\alpha}^{\text{tr}}(T) = \frac{1}{2} \left[ D(T) \right]^{-1} \sum_{n=0}^{\infty} \frac{1 - \omega_n^2}{(1 + \omega_n^2)^3},$$

$$V_{\lambda\alpha}^{\text{tr}}(T) = \frac{1}{2} \left[ D(T) \right]^{-1} \sum_{n=0}^{\infty} \frac{1}{(1 + \omega_n^2)^3},$$

where $\omega_n \equiv \frac{T}{n + \frac{1}{2}}$, $D(T)$ is defined in Eq. (36c), and $V_{\Delta}(T)$ in the formula for $V_{\lambda\alpha}(T)$ is defined in Eq. (37b). For zero temperature, we derive the following result for the gap correction

$$\lambda_{1\alpha}^{-2}(0) = -\frac{\pi}{8} \lambda_{0\alpha}^{-2} \left( \frac{1}{2\tau_{\text{tr}} \Delta_0} + \frac{1}{\tau_{\text{tr}} \Delta_0} \right)$$  

(B17)

with $\lambda_{0\alpha}^{-2} = 8\pi^3 \nu^2 / \phi_0^2$. Therefore, the correction to the London penetration depth at $T = 0$ in the clean case is proportional to transport scattering rates for both scattering channels.

---
