**IMMEDIATE POSTOPERATIVE REHABILITATION FOR PATIENTS WITH NEWLY-DIAGNOSED GLIOMA**

Mitsuyo Ikeda1, Shin Yamada, Yasutomo Okajima, Kenki Saito, Kenichi Kobayashi, Yoshiaki Shikokawa, Motoo Nagane; 1Division of Rehabilitation Service, Kyouin University Hospital, Tokyo, Japan

**BACKGROUND:** Importance of early intensive rehabilitation is recently emphasized not only for Stroke Unit but for Intensive Care Unit. We have started such early comprehensive rehabilitation for patients after brain tumor surgery. Rehabilitation therapists were specially assigned to our brain surgery unit as members of the ward staffs. The purpose of this study is to show how this rehabilitation trial works for post-surgery patients with glioma.

**METHODS:** Thirty-two patients with glioma (20 males and 12 females) who were admitted to our institution in the year of 2018 were included. Mean age was 61.8±13.3 years; glioblastoma was the major tumor type (24 patients). We retrospectively analyzed rehabilitation outcome focusing on improvement of the Functional Independence Measure (FIM) scores during hospitalization. **RESULTS:** Mean duration from surgery to the first rehabilitation intervention was 2.4±1.2 days, and mean hospital stay was 74.4±31.4 days. Twenty patients were discharged to home (62%) and 12 were transferred to other hospitals for convalescence. Motor, cognitive and total FIM scores were 41.0±22.2, 18.0±7.5, and 59.1±27.3 before surgery, whereas they were 61.4±28.6, 21.5±9.4, and 83.2±36.9, respectively, at discharge. Motor FIM items revealed more remarkable improvement than those of cognitive ones. Since starting the early intensive rehabilitation trial, patients with brain tumor have been systematically rehabilitated with an organized manner before and after surgery.

**CONCLUSION:** Early intensive rehabilitation for patients with brain tumor is recommended to be done by on-ward therapists who are assigned to work specially as members of the ward. Both motor and cognitive improvement is expected during hospitalization even in patients with malignant brain tumors.

**PRESOCRACY AND DELAYED COMPLICATIONS OF MEDULLOBLASTOMA IN KOBEE CHILDREN’S HOSPITAL**

Atsufumi Kawamura1, Junji Koyama1, Nobuyuki Akutsu, Shunsuke Yamamisu1; 1Department of Neurosurgery, Hyogo Prefectural Kobe Children’s Hospital, Hyogo, Japan

Medulloblastoma is the most common pediatric malignant tumor and about 84.2% of cases are under 15 years old. With a current combined-modality approach that includes surgical approach, chemotherapy and radiation therapy, 5-year survival rates have become 70–85% and also the so-called long-term survivors have increased in our country. This report reviews the prognostic and delayed complications of medulloblastoma in our institute. Cases were 14 boys and 11 girls from January,2010 to May, 2019. Mean age was 6.5 years old (4 months to 14 years old), 18 cases received gross total removal and 12 cases were high risk group. Eleven cases had relapsed or new tumor. The details are that 5 year survival rates in our institute is 88.8% and 4 cases had neuro-psychological complications, 5 cases had complications from endocrinal disorders which were not confirmed after the end of all treatments. 2 secondary cancer had appeared 5 and 8 years after the first treatments. The more the survivor in medulloblastoma cases increase, neurosurgeons have to consider long term follow up more than 5 years and pay more attention to support activity of daily life of these patients.

**END-OF-LIFE PHASE OF GLOMIBLASTOMA**

Tomoko Omura1, Yasuyi Miyakita1, Takaki Omura1, Makoto Ohno1, Masamichi Takahashi1, Natsuko Satomi1, Kenji Fujimoto1, Yoshitaka Naito1; 1National Cancer Center Hospital

**BACKGROUND:** Despite aggressive treatment with surgery and chemoradiation therapy, it is difficult to cure patients with glioblastoma (GBM). The end-of-life (EOL) phase of patients with GBM, and related problems, have not been sufficiently studied. Many cancer patients died in the hospital (84%) in 2017, but the Japanese government has recommended palliative home-care and the number of deaths at home has recently been increasing. This study explores the current situation of EOL care for GBM patients in our hospital.

**METHODS:** We retrospectively examined clinical course and EOL phase of 166 consecutive patients who were treated in our hospital between 2010 and 2017. **RESULTS:** In total, 107 patients died; 28 (26%) at home, 25 (23%) in hospice care, 99 (95%) in nursing homes, 21 (20%) in long-term care hospitals (LTC), 13 (12%) in our hospital, and 11 (10%) in other neurological hospitals. The median survival time and length of EOL phase for patients who died at home were 596 and 77 days; 469 and 103 days in hospice care; 528 days and 149 days in LTC; 388 days and 52 days in our hospital; 802 and 91 days in other neurological hospital; and 565 days and 53 days in nursing homes, respectively. The EOL patients who transferred to LTC or was started palliative care in other neurological hospital was 60. That of other patients was 50. The patients who died at home entered deep coma in the last 3.5 days (n=24) of life and could not take oral feeds for 7 days (n=26). **CONCLUSION:** According to our patient study, the brain-based palliative care team were 59 days. EOL phase of GBM may be longer than other cancer. We must consider the problems of the EOL phase and improve the quality of EOL care.

**SHORT-TERM INTENSIVE REHABILITATION FOR PATIENTS WITH NEWLY-DIAGNOSED MALIGNANT GLIOMA WITH SPECIAL REFERENCE TO MEDICAL COOPERATION TEAM**

Takeshi Maeda1, Masao Matsutani1, Momoka Kato1; Daijiro Okamura1, Syoschi Muraya1; 1GOTANDA rehabilitation hospital

**PURPOSE:** Many reports presented that patients with GBM had stable HRQoL during their remission time. However, there are few reports on the situation of ADL that is the basis of QOL. This prospective study was designed to evaluate the effectiveness of intensive rehabilitation for physically disabled patients with GBM after the initial treatment.

**PATIENTS AND METHOD:** Twelve patients with newly-diagnosed glioblastoma presenting with severe physical disabilities were registered after the completion of postsurgical radiation therapy combined with TMZ. All patients were evaluated by means of a core set of clinical scales of Functional Independence Measure (FIM), Sitting Balance score, Standing Balance score, and Mimi-mental State Examination (MMSE). Patients were evaluated before the beginning and at the end of rehabilitation treatment. The daily rehabilitation program consisted of individual 180-min sessions of treatment, seven days a week, for four to six consecutive weeks. Speech therapy was included when aphasia was diagnosed.

**RESULTS:** Ten of 12 patients presented with mean increased FIM score of 26.6 points that reached the individual maximum point within 10 to 56 days. **CONCLUSION:** A short-time intensive rehabilitation (4 to 6 weeks) is effective for GBM patients during TMZ withdrawal period after the postoperative radiation therapy. This effective program requires close teamwork with the medical cooperation team of the medical and rehabilitation hospitals: explanation to patients and relatives, explanation of the significance of the short-term rehabilitation, which is different from stroke rehabilitation, adjustment of hospitalization date considering radiotherapy and chemotherapy schedule, and adjustment of MRI imaging or bevacizumab administration schedule during rehabilitation.
