Fairlamb, Alexis Valentin, Bertrand Courtioux, and Pierre Verhaeghe*

ABSTRACT: An antikinetoplastid pharmacomodulation study was conducted at position 6 of the 8-nitroquinolin-2(1H)-one pharmacophore. Fifteen new derivatives were synthesized and evaluated in vitro against L. infantum, T. brucei brucei, and T. cruzi, in parallel with a cytotoxicity assay on the human HepG2 cell line. A potent and selective 6-bromo-substituted antitrypanosomal derivative 12 was revealed, presenting EC50 values of 12 and 500 nM on T. b. brucei trypanastigotes and T. cruzi amastigotes respectively, in comparison with four reference drugs (30 nM ≤ EC50 ≤ 13 μM). Moreover, compound 12 was not genotoxic in the comet assay and showed high in vitro microsomal stability (half life >40 min) as well as favorable pharmacokinetic behavior in the mouse after oral administration. Finally, molecule 12 (E° = −0.37 V/NHE) was shown to be bioactivated by type 1 nitroreductases, in both Leishmania and Trypanosoma, and appears to be a good candidate to search for novel antitrypanosomal lead compounds.

KEYWORDS: Trypanosoma brucei brucei, Trypanosoma cruzi, 8-nitroquinolin-2(1H)-ones, redox potentials, NTR1

Human African trypanosomiasis (HAT),1 Chagas diseases (CD),2 and visceral leishmaniasis (VL)3 are infectious diseases caused by unicellular flagellated kinetoplastid parasites belonging to the Trypanosoma and Leishmania genera. From an epidemiological point of view, the World Health Organization (WHO) estimates that millions of people are at risk of contracting HAT, CD, and VL. These three diseases are also estimated to be responsible for about 30 000 annual deaths, with the caveat that these numbers may be underestimated due to the difficulty in accessing some rural areas and the unspecific symptoms during the early stage of these infections.4 Although these diseases are lethal if untreated, there are very few efficient and safe drugs available, each of them presenting various drawbacks for the patient (toxicity, emergence of resistances, mode of administration, treatment cost). Thus because of the lack of consideration and investments from the pharmaceutical industry, the WHO classified HAT, CD, and VL among “neglected tropical diseases” (NTDs).5

In this context, nitroaromatic derivatives play a key role in the fight against kinetoplastids (Figure 1). Beyond Nifurtimox and Benznidazole (antiparasitic drugs), nitroaromatics are fully part of the research efforts of the Drugs for Neglected Diseases initiative (DNDi). Thus among the few novel chemical entities in clinical trials against these infections,6 the development of fexinidazole (an orally available 5-nitroimidazole derivative that received an agreement from the European Medicines Agency (EMA) in the treatment of HAT in 2018 and that is in phase 2 against CD),7,8 delamanid (a derivative that is marketed against tuberculosis and that was studied against VL),10 and DNDi-0690 (a 2-nitroimidazoazole derivative from delamanid and that has recently entered phase-I clinical trials against VL) illustrate well the strong potential of nitroaromatic molecules in the search for novel antiparasiticam0s.

The antiparasitic mechanism of action of these molecules involves parasitic nitroreductases (NTRs). NTRs contain a flavin as a cofactor and catalyze the one- or two-electron reduction of nitrodrugs into cytotoxic electrophilic metabolites such as nitroso and hydroxylamine derivatives, which are able to form covalent adducts with DNA or proteins.9 Two NTRs were found in Leishmania: a mitochondrial NTR1 catalyzing a two-electron reduction13 and a cytosolic NTR2 catalyzing a one-electron reduction.14 In Trypanosoma, only a mitochondrial type 1 NTR is expressed.15,16 It is important to note that...
these enzymes are absent from mammalian cells, an important feature for developing selective antikinetoplastid molecules. Moreover, depending on the chemical structure of nitrated derivatives, the selectivity for NTRs could be modulated. For instance, fexinidazole is selectively bioactivated by NTR1 in both *Leishmania* and *Trypanosoma*; meanwhile, delamanid is only bioactivated by NTR2 in *Leishmania*. 14

In this context, by studying the antiparasitic potential of the 8-nitroquinoline scaffold, 17 our research team reported a new antileishmanial pharmacophore: 8-nitroquinolin-2(1H)-one. 18 After pharmacomodulation studies at position 4, 19,20 an electrochemistry-guided work highlighted the importance of an intramolecular hydrogen bond between the nitro group and the lactam function. 21 This work also led to the identification of a new 3-bromosubstituted antikinetoplastid hit compound derivative (Hit 1, Figure 2), which is bioactivated by type 1 NTRs, in both *L. donovani* and *T. brucei brucei* (T. b. brucei). 21

Recently, by introducing a *p*-carboxyphenyl functionality at position 3 of the pharmacophore, we reported a new selective antitrypanosomal hit compound (Hit 2, Figure 2). 22

We herein present a medicinal chemistry work that greatly improved the antitrypanosomal activity of the current series via the synthesis of novel derivatives bearing electron-withdrawing groups at position 6 of the quinolinone scaffold.

To increase the oxidant character of the series and facilitate its bioactivation by nitroreductases, 15 derivatives (1−15) were prepared, bearing various electron-withdrawing groups (EWGs) at position 6. As presented in Scheme 1, eight compounds bearing a trifluoromethyl group at position 6 of the quinolinone scaffold were synthesized according to a previously reported protocol. 23 In brief, 3-ethoxycryloyl chloride was synthesized in two steps by the saponification...
of commercial 3,3′-diethoxyethylpropionate followed by a reaction with thionyl chloride. This acyl chloride was then reacted with p-trifluoromethylaniline to afford, after a cyclization step in H₂SO₄ (98%), compound 1 in 42% yield (a). Molecule 1 was then either nitrated at position 8, using classical conditions, to afford compound 2 in 89% yield (b) or selectively halogenated at position 3 to generate derivative 3 or 4 in 48 and 54% yield, respectively (c and d). The O-methylation of compound 2 was performed with a protocol using a mixture of methyl iodide and sodium hydride to prepare derivative 5 in 69% yield (e). Nitrated molecule 2 could also undergo chlorination at position 3, affording compound 6 in 88% yield (f), or react with NaBrO₃ in refluxing HBr, leading to 12 in good yield (d). Taking into account that we previously reported the benefit of introducing a p-carboxyphenyl moiety at position 3 of the scaffold toward antitrypanosomal activity, we finally engaged dibromo-derivative 10 into a Suzuki−Miyaura reaction with p-(methoxycarbonyl)phenylboronic acid and then saponified the resulting ester coupling product to afford carboxylic acid 13 (e). Finally, from brominated compound 12, derivatives 14 and 15 were obtained through a Sonogashira coupling reaction (f).

Figure 3. Redox potentials of synthesized nitroaromatic compounds determined by cyclic voltammetry.

Electrochemistry. Because the compounds were expected to be nitroreductase substrates, we studied the influence of the introduction of EWGs at position 6 of the pharmacophore toward redox potentials. Thus redox potentials (couple R-N=O/RNO2) of the synthesized compounds were measured by cyclic voltammetry in DMSO (one-electron reversible reduction). Redox potentials ranged between −0.36 and −0.75 V/NHE (Figure 3). In comparison with the original pharmacophore, the introduction of a bromine atom at position 6 (compound 9) led to a significant increase in the E° value from −0.54 to −0.40 V. The same effect was observed when a bromine atom was introduced at position 6 of hit 2 (compound 13), with an increase in the E° value of +0.16 V. It is important to note that introducing a bromine atom has a higher influence on the redox potential at position 6 (compound 9) compared with position 3 (hit 1): +0.14 versus +0.09 V. The influence of the CF3 group toward the redox potential of the scaffold was the same as that of the bromine atom: +0.15 V (comparison between the pharmacophore and compound 2). Then, when two bromine atoms were combined at positions 3 and 6 (compound 10), a slight increase of +0.03 V was observed (no additive effect) in comparison with 6-bromo-derivative 9. Surprisingly, by comparing compounds 7 and 10−12, there was almost no effect of the variation of the EWG at position 3 or 6 toward the redox potential values, with all compounds ranging from −0.36 to −0.37 V. Finally, by comparing compound 2 with its O-methylated derivative 5, it appeared that the redox potential value was drastically lower (−0.36 V shift). This shift is not only due to the donating mesomeric effect of the methoxy group but also due to the disappearance of the intramolecular hydrogen bond between the nitro group and the lactam function.21

**Compound Evaluation.** The cytotoxicity of all compounds was first assessed on the human HepG2 cell line using doxorubicin as a positive control (Table 1). Compared with this reference drug (EC50 = 0.2 μM), the series showed little (CC50 = 17 μM) to no (CC50 > 100 μM) cytotoxicity. Non-nitrated molecules 1, 3, and 4, O-methylated derivative 5, and 8-amino-derivative 8, considered as negative controls, displayed high CC50 values, >100 μM. The results show that the introduction of a bromine atom or a CF3 group at position 6 of the nitrated scaffold leads to derivatives (2 and 9) that are four to five times more cytotoxic (CC50 = 28−41 μM) than the 8-nitroquinolinone pharmacophore (CC50 = 164 μM). When introducing an additional halogen atom at position 3 of the scaffold (6, 7, 10−12), the cytotoxicity remains close to the ones of 6-monosubstituted derivatives (CC50 = 17−41 μM). Nevertheless, introducing a p-carboxyphenyl functionality at position 3 of the scaffold (compound 13) results in a three-fold decrease in the cytotoxicity (CC50 = 60 μM) in comparison with the 3,6-dibromo derivative 10 (CC50 = 17 μM).

All synthesized molecules were screened in vitro for their activity against *Leishmania infantum* axenic amastigotes, and their EC50 values were compared with the ones of three reference drugs (amphotericin B, miltefosine, and fexinidazole) and antikinetoplastid hit 1 (Table 1). Among the tested compounds, only compound 7 (E° = −0.36 V) showed a weak antileishmanial activity, displaying an EC50 value of 3.9 μM in addition to a selectivity index superior to 10. Derivatives of 7 without a nitro group at position 8 of the scaffold (1, 3, 4, and 8) were inactive toward *L. infantum* as well as the O-methylated analogue 5 (E° = −0.75 V), confirming both the key role of the nitro group toward antiparasitic activity and the importance of the interaction between the nitro group and the lactam function to confer suitable redox potentials for displaying antileishmanial properties in this chemical series.

Note that, contrary to hit 2, which was not active against *L. infantum* (EC50 > 100 μM), the 6-bromo derivative 13 was active (EC50 = 8 μM). All molecules were also screened in vitro for their antitrypanosomal activity against *T. b. brucei* trypomastigotes, and their EC50 values were compared with the ones of three reference drugs, suramin, eflorenithine, and fexinidazole, and with antitrypanosomal hit 2. Among the 15 tested molecules, 7, 9, 10, 11, 12, and 13 displayed both submicromolar activity (12 ≤ EC50 ≤ 200 nM) and good selectivity indices (SI > 200) in comparison with suramin (EC50 = 30 nM), eflorenithine (EC50 = 13 μM), fexinidazole (EC50 = 400 nM), and hit 2 (EC50 = 1.5 μM). Molecule 12 was the most active and selective in the series: EC50 = 12 nM and SI = 1508. Compounds without a nitro group at position 8 of the scaffold

*Calculated with MarvinSketch (ChemAxon).

appeared to be inactive (compounds 1, 3, and 4), and amino-derivative 8 was quite less active (EC_{50} = 9 μM). It is important to note that the introduction of a bromine atom at position 6 of the scaffold seems crucial to afford highly active antitrypanosomal molecules, with compound 9 being 334 times more active than the 8-nitroquinolinol-2(1H)-one pharmacophore and 27 times more active than its 3-bromo isomer (hit 1). This key effect of the bromine atom at position 6 of the scaffold also appears when comparing the activities of 3-chloro-6-bromo hit-compound 12 with its 3-chloro-analogue A: 12 is 100 times more active than A. When comparing molecules 2 and 9, it appeared that the CF_{3} group does not provide the same level of improvement in activity. Introducing an additional halogen at position 3 of hit molecule 9, leading to dibromo-derivative 10 and dihalo-derivative 12, afforded the most active compounds in the series (EC_{50} = 12–50 nM). A comparison between compound 12 and 3,6-dichlorosubstituted derivative 11 showed that the replacement of the bromine atom by a chlorine atom at position 6 was not in favor of antitrypanosomal activity. During pharmacomodulation studies at position 3 of the scaffold, hit 2 was identified as a promising antitrypanosomal hit with an EC_{50} of 1.5 μM. When a bromine atom is introduced at position 6 of hit 2, leading to compound 13, the antitrypanosomal activity is improved, reaching an EC_{50} value of 200 nM.

Thus the molecule presenting the best antitrypanosomal profile in the series, regarding both the activity and the selectivity, was compound 12. To better evaluate its antitrypanosomal potential, an in vitro evaluation against intracellular T. cruzi amastigotes was carried out using benzimidazole and fexinidazole as positive controls (Table 1). Quite interestingly, despite being about 10 times more cytotoxic than reference drugs, molecule 12 displayed a high activity (EC_{50} = 0.5 μM) against T. cruzi, identical to the one of benzimidazole (EC_{50} = 0.5 μM) and better than the one of fexinidazole (EC_{50} = 3 μM).

To investigate more deeply the potential of compounds 7, 12, and 13 as the most active antikinetoplastid compounds of the studied series, an in vitro pharmacokinetic evaluation was performed, including a microsomal stability assay (female mouse microsomes), a human albumin binding assay, and a PAMPA assay using a blood–brain barrier (BBB) model (Table 2). All compounds presented good microsomal stability (T_{1/2} > 40 min) and strong binding to human albumin (≥99%). However, the development of antitrypanosomal agents requires that molecules cross the BBB, as the second stage of HAT is meningoencephalitic. A PAMPA assay on a BBB model was then performed. Compounds 7 and 12 diffused through the lipid bilayer with Pe values significantly higher than the positive control (Pe = 450.3 and 405.1 nm/s, respectively), whereas compound 13 displayed a low Pe value (Pe = 12.7 nm/s), indicating a limited crossing of the BBB, hindering the further development of 13. This last result is not surprising because electrostatic repulsions between the negatively charged carboxylic acid group of this molecule and the negatively charged membrane constituents are probably responsible for its low permeability across the BBB in the PAMPA model. Moreover, 13 has a molecular weight approaching 400 g/mol, which could also contribute to limiting its diffusion across the BBB. Unfortunately, the methylic ester precursor or 13 could not be evaluated in vitro because of a lack of aqueous solubility. The ability of hit-compound 12 to cross the BBB in the PAMPA assay is in accordance with its central nervous system multiparameter optimization (CNS MPO) score that has a calculated value of 4.35. Finally, the aqueous solubility of hit-compound 12 was measured with a thermodynamic solubility assay at physiological pH and was determined at 21.7 μM (Table 2).

To check the antikinetoplastid mechanism of the bio-activation of compounds 7, 12, and 13, their activities were evaluated in vitro toward Leishmania donovani promastigote strains overexpressing leishmanial nitroreductases (NTR1 or NTR2). EC_{50} values were determined and compared with the ones obtained on a wild-type strain to evaluate the
bioactivation of these nitroaromatic compounds (Table 3). As reported for hit 1,21 compounds 7 and 12 are selectively

Table 3. Evaluation of the Bioactivation of Compounds 7, 12, and 13 by Leishmanial and Trypanosomal NTRs

|------------------------------------------|-----------|
| compound                                 | wild type | NTR overexpressing |
| Hit 1                                    | 17.7 ± 1.0 | 3.9 ± 0.1 |
| Hit 2                                    | 5.4 ± 0.12 | 4.2 ± 0.2 |
| 7                                       | 6.7 ± 0.4 | 0.9 ± 0.03 |
| 12                                      | 0.3 ± 0.06 | 0.02 ± 0.008 |
| 13                                      | 4.0 ± 0.2 | 0.4 ± 0.009 |
| Nifurtimox                               | 1.9 ± 0.05 | 0.6 ± 0.05 |

bioactivated by leishmanial NTR1, with EC50 values being 3.5 and 16 times lower on the strain overexpressing the NTR than on the wild type. Contrary to 7 and 12, compound 13 did not demonstrate significant bioactivation by NTR1 or by NTR2 in Leishmania. The same experiments were carried out with compounds 7, 12, and 13 on T. b. brucei strains overexpressing the type 1 trypanosomal NTR, comparing the EC50 values with the ones determined on the wild type strain (Table 3). All tested compounds were bioactivated by the type 1 nitroreductase of T. b. brucei, being, respectively, 7, 15, and 40 times more active against the strain overexpressing the NTR than against the wild type. It is interesting to note that hit 2 (E° = −0.56 V) did not seem to be bioactivated by T. b. brucei NTR, whereas its 6-brominated derivative 13 (E° = −0.40 V) was. Finally, hit-compound 12 also appeared to be six times more active than nifurtimox against T. b. brucei, underlining the potential of this molecule as an antitypanosomal candidate.

Even though many safe nitroaromatic molecules are today on the market (for example, antiprotocoal 5-nitroimidazoles such as metronidazole, some benzodiazepines like lorazepam, anti-Parkinson’s catechol O-methyltransferase (COMT) inhibitors like entacapone, antiandrogens like flutamide, anti-inflammatory nimesulide, immunomodulating azathioprine, anticoagulant acenocoumarol, antihemophilic nicasamide, etc.) or in clinical trials (for instance, delamanid), drugs including a nitroaromatic moiety suffer from a bad reputation as possible mutagenic or genotoxic molecules, which narrows their pharmaceutical development.29 The Ames test is the most commonly used assay to evaluate the mutagenic potential of compounds, using Salmonella typhimurium strains. However, these bacteria possess NTR, making the Ames test generally unsuitable for the evaluation of most of nitroaromatic compounds, with the genotoxicity being attributed to the reduced metabolites that are bioactivated by these bacterial enzymes (absent in human cells).30 Thus it is accepted that the comet assay or the micronucleus assay are more pertinent methods to evaluate the genotoxic potential of nitroaromatic compounds. For example, fexinidazole is positive in the Ames test but negative in the micronucleus assay.31 A comet assay was then performed on the HepG2 cell line with hit compound 12, using methylmethanesulphonate (MMS) as a positive control (see the Supporting Information). Compound 12 was not genotoxic after 2 or 72 h of incubation or at 1 or 10 μM, concentrations chosen to be lower than its CC50 on HepG2 cell line (CC50 = 18 μM).

Regarding tolerance in the mouse, a once daily oral dose of compound 12, at 25 or 50 mg/kg, was administrated to eight mice (four mice in each group). These two doses were well tolerated with just a little apathy during 1 h for all mice receiving the dose of 50 mg/kg. The administration of a repeated dose of 25 mg/kg once daily for 5 days was well tolerated without any adverse effect noted. The no-observed-adverse-effect level (NOAEL)31 in mice was then set at 25 mg/kg/day. After euthanasia, no lesions were found on the different organs (kidney, liver, brain, heart, and lung).

Finally, the in vivo pharmacokinetic parameters were determined in the mouse, after oral administration at 25 mg/kg in a mixture of 5% Tween 80 and 95% of 0.5% carboxymethylcellulose in water, by using the QuEChERS method.32 Monolix SoftX software was used to analyze the data by a noncompartmental model to fit pharmacokinetics parameters.33 As presented in the Supporting Information (Figure S17), hit-compound 12 showed good pharmacokinetic properties: 12 is highly and rapidly absorbed after oral administration and shows good exposure. Its plasmatic half life (2.9 h) is higher than the one of the drug fexinidazole (0.8 h).31

Conclusions. Via an antitypanosomal pharmacomodulation study of the 8-nitroquinolin-2(1H)-one scaffold, by introducing an EWG at positions 3 and 6 of the quinolinone ring, a novel potent antitypanosomal hit-compound (12) was identified, displaying high activities toward T. b. brucei (EC50 = 12 nM) and T. cruzi (EC50 = 0.5 μM) in comparison with efomithine (EC50 = 13 μM), suramin (EC50 = 30 nM), benzimidazole (EC50 = 0.5 μM), and fexinidazole (EC50 = 0.4 and 3.0 μM). Compound 12 displays good in vitro pharmacokinetic parameters (good microsomal stability and BBB permeability), is rapidly absorbed after oral administration, and is well tolerated in the mouse at 25 mg/kg. Nitroaromatic hit compound 12 is selectively bioactivated by type 1 NTR in both Leishmania and Trypanosoma. An electrochemistry study showed the strong influence of the introduction of an EWG in the benzenic part of the pharmacophore toward the redox potentials and the corresponding antitypanosomal activities. Finally, the lack of genotoxicity of compound 12 in the comet assay is an additional favorable element so as to consider further development. Compound 12 meets all criteria for an antitypanosomal hit, as defined by Katsuno and coworkers.34 In vivo studies on the mice model of trypanosomiasis are now planned to investigate the potential of this compound to become an antitypanosomal lead.

1. Material and methods

Chemistry

All reagents and solvents were obtained from commercial sources (Fluorochem®, Sigma-Aldrich® or Alfa Aesar®) and used as received. The progress of the reactions was monitored by pre-coated thin layer chromatography (TLC) sheets ALUGRAM® SIL G/UV254 from Macherey-Nagel and were visualized by ultraviolet light at 254 nm. The $^1$H and $^{13}$C-NMR spectra were recorded on a Bruker UltraShield 300 MHz, a Bruker IconNMR 400 MHz, or a Bruker Avance NEO 600 MHz instrument and data are presented as follows: chemical shifts in parts per million (δ) using tetramethylsilane (TMS) as reference, coupling constant in Hertz (Hz), multiplicity by abbreviations: (s) singlet, (d) doublet, (t) triplet, (q) quartet, (dd) doublet of doublets, (m) multiplet and (br s) broad singlet. Melting points are uncorrected and were measured on a Stuart Melting Point SMP3 instrument. High-resolution mass measurements were done on a GCT Premier Spectrometer (DCI, CH₄, HRMS) or Xevo G2 QTOF (Waters, ESI+, HRMS) instrument at the Université Paul Sabatier, Toulouse. Microwave reactions were operated in a CEM Discover® microwave reactor.

Preparation of 6-trifluoromethylquinolin-2(1H)-one 1

In a first step, 4.5 g of 3,3’-diethoxyacryloyl chloride (33.4 mmol, 1.2 equiv.), prepared from ethyl 3,3’-diethoxypropionate by a saponification followed by a reaction with SOCl₂, were added dropwise at rt onto 3.5 mL of o-trifluoromethylaniline (27.8 mmol, 1 equiv.) in 50 mL of dichloromethane, in the presence of 4.5 mL of pyridine (55.6 mmol, 2 equiv.). After 6 h, the reaction mixture was poured into
water, neutralized with HCl and extracted three times with dichloromethane (3 × 100 mL). The resulting organic layer was washed with brine, dried over anhydrous Na$_2$SO$_4$ and evaporated *in vacuo* to afford a dark oil. In a second step, the crude residue was reacted with 98% sulfuric acid (40 mL) and stirred at rt for 2 h (monitored by TLC). The reaction mixture was then poured into ice, neutralized with K$_2$CO$_3$ and extracted twice with dichloromethane (2 × 100 mL) and once with ethyl acetate (100 mL). The resulting organic layer was washed with water, dried over anhydrous Na$_2$SO$_4$ and evaporated *in vacuo*. The crude residue was purified by chromatography on silica gel using ethyl acetate as an eluent. Compound 1 was isolated and recrystallized in isopropanol to yield a white solid (42%, 11.68 mmol, 2.5 g).

**Compound 1** (C$_{10}$H$_6$F$_3$NO): mp 201 °C, $^1$H NMR (400 MHz, CDCl$_3$) $\delta$: 6.83 (d, 1H, $J$ = 9.6 Hz, H3), 7.54 (d, 1H, $J$ = 8.7 Hz, H8), 7.76 (dd, 1H, $J$ = 1.8 and 8.7 Hz, H7), 7.89 (d, 1H, $J$ = 1.8 Hz, H5), 7.90 (d, 1H, $J$ = 9.6 Hz, H4), 12.43 (br s, 1H, NH). $^{13}$C NMR (100 MHz, CDCl$_3$) $\delta$: 116.8 (CH), 119.3 (C), 122.9 (CH), 123.9 (q, $J$=271.6 Hz, C), 125.2 (q, $J$=33.2 Hz, C), 125.4 (q, $J$=4.1 Hz, CH), 127.1 (q, $J$=3.4 Hz, CH), 140.4 (C), 140.8 (CH), 164.6 (C). HRMS (DCI CH$_4$) caled for C$_{10}$H$_7$F$_3$NO [M+H]$^+$ 214.0480, found 214.0475.

**Preparation of 8-nitro-6-trifluoromethylquinolin-2(1H)-one 2**

H$_2$SO$_4$ (98%, 10 mL) were added onto 500 mg of 6-trifluoromethylquinolin-2(1H)-one 1 (2.34 mmol, 1 equiv.), cooled with an ice bath. 0.96 mL of 65% HNO$_3$ (14.1 mmol, 5 equiv.) were then added dropwise at 0°C and the reaction mixture was stirred at rt for 2 h. The reaction mixture was successively poured into ice, neutralized with K$_2$CO$_3$, extracted three times with dichloromethane (3 × 50 mL) and once with ethyl acetate (50 mL). The organic layer was washed with water, dried over anhydrous MgSO$_4$ and evaporated *in vacuo*. The crude residue was purified by chromatography on silica gel using ethyl acetate as an eluent. Compound 2 was isolated and recrystallized in acetonitrile to yield a pale yellow solid (89%, 2.1 mmol, 540 mg).

**Compound 2** (C$_{10}$H$_5$F$_3$N$_2$O$_3$): mp 177 °C, $^1$H NMR (400 MHz, CDCl$_3$) $\delta$: 6.86 (dd, 1H, $J$ = 9.8 and 1.9 Hz, H3), 7.85 (d, 1H, $J$ = 9.8 Hz, H4), 8.12 (d, 1H, $J$ = 2.0 Hz, H5), 8.73 (d, 1H, $J$ = 2.0 Hz, H7), 11.33 (br s, 1H, NH). $^{13}$C NMR (100 MHz, CDCl$_3$) $\delta$: 122.4 (C), 122.6 (q, $J$ = 271.6 Hz, C), 124.1 (q, $J$ = 35.2 Hz, CH), 140.4 (C), 164.6 (C). HRMS (DCI CH$_4$) caled for C$_{10}$H$_5$F$_3$N$_2$O$_3$ [M+H]$^+$ 255.0647, found 255.0638.
S4 Hz, C), 124.8 (q, \( J = 3.4 \text{ Hz}, \text{CH} \), 125.2 (CH), 131.9 (q, \( J = 3.4 \text{ Hz}, \text{CH} \), 132.7 (C), 135.7 (C), 139.5 (CH), 161.0 (C). HRMS (ESI+) calcd for C_{10}H_{6}F_{3}N_{2}O_{3} [M+H]^+ 259.0331 found 259.0333.

Preparation of 3-chloro-6-trifluoromethylquinolin-2(1H)-one 3
A solution of 15 mL of hydrochloric acid (37%) was added onto 500 mg of 6-trifluoromethylquinolin-2(1H)-one 1 (2.35 mmol, 1 equiv.). The reaction mixture was then stirred at 100 °C before 300 mg of sodium chlorate (2.8 mmol, 1.2 equiv.) were added with caution (Cl₂ formation). After 7 h under reflux, the reaction mixture was left for 1 h under the hood to evacuate remaining Cl₂ vapor, and then was poured into ice, neutralized with K₂CO₃, extracted three times with dichloromethane (3 × 50 mL) and once with ethyl acetate (50 mL). The organic layer was washed with water, dried over anhydrous MgSO₄ and evaporated in vacuo. The crude residue was purified by chromatography on silica gel using dichloromethane/ethyl acetate (90/10) as an eluent. Compound 3 was isolated and recrystallized in isopropanol to yield a white solid (48%, 1.1 mmol, 280 mg).

Compound 3 (C_{10}H_{5}ClF_{3}NO), mp 210 °C, \(^1\text{H NMR (400 MHz, CDCl}_3)\) \( \delta: 7.63 (d, 1H, J = 8.7 \text{ Hz}, \text{H8}), 7.76 (d d, 1H, J = 8.8 \text{ and } 1.4 \text{ Hz, H7}), 7.83 (d, J = 1.4 \text{ Hz, 1H, H5}), 8.07 (s, 1H, H4), 12.6 \text{ (br s, 1H, NH)}. \(^{13}\text{C NMR (100 MHz, CDCl}_3)\) \( \delta: 117.0 \text{ (CH)}, 119.0 \text{ (C)}, 123.7 \text{ (C, J = 271.8 Hz)}, 124.6 \text{ (CH, J = 4.2 Hz)}, 125.9 \text{ (C, J = 33.3 Hz)}, 127.1 \text{ (CH, J = 3.3 Hz)}, 128.0 \text{ (C)}, 138.0 \text{ (CH)}, 138.9 \text{ (C)}, 160.3 \text{ (C)}.\) HRMS (DCI CH₄) calcd for C_{10}H_{6}ClF_{3}NO [M+H]^+ 248.0090, found 248.0079.

Preparation of 3-bromo-6-trifluoromethylquinolin-2(1H)-one 4
6-Trifluoromethylquinolin-2(1H)-one 1 (1.87 mmol, 400 mg) and 835 mg of \( N\)-bromosuccinimide (4.69 mmol, 2.5 equiv.) were added in a sealed flask of 25 mL. Then, 10 mL of acetonitrile were added and the reaction mixture was heated at 140 °C in a microwave reactor during 2 hours. The reaction mixture was poured into water and extracted three times with dichloromethane (3 × 50 mL). The organic layer was washed twice with a sodium carbonate solution (pH = 8) and twice with a diluted hydrochloric acid solution (pH=4), dried over anhydrous Na₂SO₄ and evaporated in vacuo. The crude residue was purified by chromatography on silica gel using dichloromethane/ethyl acetate (75/25) as an eluent. Compound 4 was isolated and recrystallized in acetonitrile to yield a white solid (54%, 1.0 mmol, 293 mg).

54
Compound 4 (C_{10}H_{5}BrF_{3}NO), mp 233 °C, {^1}H NMR (400 MHz, CDCl\textsubscript{3}) δ: 7.58 (d, 1H, \textit{J} = 8.7 Hz, H8), 7.78 (dd, 1H, \textit{J} = 8.7 and 1.6 Hz, H7), 7.83 (d, \textit{J} = 1.6 Hz, 1H, H5), 8.29 (s, 1H, H4), 12.23 (br s, 1H, NH). 13C NMR (100 MHz, CDCl\textsubscript{3}) δ: 116.9 (CH), 118.6 (C), 119.5 (C), 123.7 (q, \textit{J} = 272.0 Hz, C), 124.5 (q, \textit{J} = 4.1 Hz, CH), 125.8 (q, \textit{J} = 33.4 Hz, C), 127.3 (q, \textit{J} = 3.4 Hz, CH), 139.5 (C), 142.0 (CH), 160.2 (C). HRMS (ESI-) calcd for C_{10}H_{4}BrF_{3}NO \text{[M-H]} - 289.9428, found 289.9433.

Preparation of 2-methoxy-8-nitro-6-trifluoromethylquinoline 5

Under argon atmosphere, 250 mg of 8-nitro-6-trifluoromethylquinolin-2(1H)-one 2 (0.97 mmol, 1 equiv.) were solubilized in 5 mL of dry DMF and were added onto a DMF solution (5 mL) of 77 mg of 60% sodium hydride (1.93 mmol, 2 equiv.). After 10 min of stirring at rt, 120 µL of methyl iodide (1.93 mmol, 2 equiv.) were added dropwise. The reaction mixture was stirred at rt during 3 h, before being poured into ice and extracted four times with ethyl acetate (4 × 25 mL). The organic layer was washed twice with water, once with brine, dried over anhydrous MgSO\textsubscript{4} and evaporated \textit{in vacuo}. The crude residue was purified by chromatography on silica gel using dichloromethane as eluent. Compound 5 was isolated and recrystallized in isopropanol to yield a white solid (69%, 0.66 mmol, 181 mg).

Compound 5 (C_{11}H_{7}N_{2}O_{3}F_{3}): mp 165 °C, {^1}H NMR (400 MHz, CDCl\textsubscript{3}) δ: 4.10 (s, 3H, CH\textsubscript{3}), 7.13 (d, 1H, \textit{J} = 8.9 Hz, H3), 8.13 (d, 1H, \textit{J} = 8.9 Hz, H4), 8.16 (d, 1H, \textit{J} = 2.0 Hz, H5), 8.20 (d, 1H, \textit{J} = 2.0 Hz, H7). 13C NMR (100 MHz, CDCl\textsubscript{3}) δ: 54.5 (CH\textsubscript{3}), 116.6 (CH), 120.3 (CH, q, \textit{J} = 3.4 Hz), 123.1 (C, q, \textit{J} = 272.4 Hz), 125.0 (C, q, \textit{J} = 35.0 Hz), 125.7 (C), 128.6 (CH, q, \textit{J} = 3.98 Hz), 138.9 (CH), 139.8 (C), 146.6 (C), 165.1 (C). HRMS (DCI CH\textsubscript{4}) calcd for C_{11}H_{8}N_{2}O_{3}F_{3} \text{[M+H]}\textsuperscript{+} 273.0487, found 273.0474.

Preparation of 3-chloro-8-nitro-6-trifluoromethylquinolin-2(1H)-one 6

A solution of 25 mL of hydrochloric acid (37%) was added onto 150 mg of 6-trifluoromethyl-8-nitroquinolin-2(1H)-one 2 (0.58 mmol, 1 equiv.). The reaction mixture was then stirred at 100 °C before 186 mg of sodium chlorate (1.74 mmol, 3 equiv.) were added with caution (Cl\textsubscript{2} formation). After 2 h under reflux, the reaction mixture was left for 1 h under the hood to evacuate remaining Cl\textsubscript{2} vapor, and then was poured into ice, neutralized with K\textsubscript{2}CO\textsubscript{3}, extracted three times with dichloromethane (3 × 25
mL) and once with ethyl acetate (25 mL). The organic layer was washed with water, dried over anhydrous MgSO₄ and evaporated in vacuo. The crude residue was isolated and recrystallized in isopropanol to yield a yellow solid (88%, 0.51 mmol, 150 mg).

Compound 6 (C₁₀H₄ClF₃N₂O₃): mp 153 °C, ¹H NMR (400 MHz, CDCl₃) δ: 8.06 (s, 1H, H₄), 8.10 (d, 1H, J = 2.0 Hz, H₅), 8.74 (d, 1H, J = 2.0 Hz, H₇), 11.55 (br s, 1H, NH). ¹³C NMR (100 MHz, CDCl₃) δ: 122.1 (C), 122.4 (C, q, J = 272.6 Hz), 124.6 (C, q, J = 3.7 Hz), 124.9 (C, q, J = 35.6 Hz), 130.9 (C), 131.1 (CH, q, J = 3.55 Hz), 132.9 (C), 134.2 (C), 136.4 (CH), 157.0 (C). HRMS (DCI CH₄) calcd for C₁₀H₅ClF₃N₂O₃ [M+H]⁺ 292.9941, found 292.9933.

Preparation of 3-bromo-8-nitro-6-trifluoromethylquinolin-2(1H)-one 7

A solution of 20 mL of hydrobromic acid (48%) was added onto 350 mg of 6-trifluoromethyl-8-nitroquinolin-2(1H)-one 2 (1.36 mmol, 1 equiv.). The reaction mixture was then stirred at 100 °C before 345 mg of sodium bromate (4.07 mmol, 3 equiv.) were added with caution (Br₂ formation). After 3 h under reflux, the reaction mixture was left for 1 h under the hood to evacuate remaining Br₂ vapor, and then was poured into ice, neutralized with K₂CO₃ and extracted three times with dichloromethane (3 × 50 mL). The organic layer was washed with water, dried over anhydrous Na₂SO₄ and evaporated in vacuo. The crude residue was purified by chromatography on silica gel using dichloromethane as an eluent. Compound 7 was isolated and recrystallized in acetonitrile to yield a pale yellow solid (94%, 1.27 mmol, 430 mg).

Compound 7 (C₁₀H₅BrF₃N₂O₃): mp 168 °C, ¹H NMR (400 MHz, CDCl₃) δ: 8.10 (d, 1H, J = 2.0 Hz, H₅), 8.29 (s, 1H, H₄), 8.76 (d, 1H, J = 2.0 Hz, H₇), 11.51 (br s, 1H, NH). ¹³C NMR (150 MHz, CDCl₃) δ: 121.6 (C), 122.4 (C, q, J = 272.6 Hz), 122.5 (C), 124.7 (C, q, J = 3.6 Hz), 124.7 (CH, q, J = 35.4 Hz), 131.0 (CH, q, J = 3.5 Hz), 132.9 (C), 134.7 (C), 140.5 (CH), 157.1 (C). HRMS (DCI CH₄) calcd for C₁₀H₅BrF₃N₂O₃ [M+H]⁺ 336.9436, found 336.9437.
Preparation of 8-amino-3-bromo-6-trifluoromethylquinolin-2(1H)-one 8

Ethanol (20 mL) was added onto 130 mg of 3-bromo-8-nitro-6-trifluoromethylquinolin-2(1H)-one 7 (0.38 mmol, 1 equiv.) and 365 mg of tin (II) chloride (1.92 mmol, 5 equiv.). The reaction mixture was refluxed for 5 h. The reaction mixture was then neutralized into an aqueous solution of K$_2$CO$_3$, filtered on celite, extracted twice with dichloromethane (3 × 50 mL) and once with ethyl acetate (50 mL). The combined organic layers were washed with water, dried over anhydrous MgSO$_4$ and evaporated in vacuo. The crude residue was washed with a diluted hydrochloric solution (pH = 1) three times. Compound 8 was isolated to yield an orange solid (68%, 0.26 mmol, 80 mg).

Compound 8 (C$_{10}$H$_6$BrF$_3$N$_2$O): Tdec. 238 °C, $^1$H NMR (300 MHz, DMSO-d$_6$) δ: 6.03 (br s, 2 H, NH$_2$), 7.06 (d, 1 H, J = 2.0 Hz, H7), 7.31 (d, 1H, J = 2.0 Hz, H5), 8.55 (s, 1H, H4), 11.67 (br s, 1H, NH). $^{13}$C NMR (100 MHz, DMSO-d$_6$) δ: 109.6 (CH, q, J = 4.3 Hz), 112.1 (CH, q, J = 4.3 Hz), 118.3 (C), 120.0 (C), 123.9 (C, q, J = 31.9 Hz), 124.8 (C, q, J = 271.9 Hz), 127.8 (C), 136.6 (C), 142.9 (CH), 158.4 (C).

HRMS (ESI +) calcd for C$_{10}$H$_6$BrF$_3$N$_2$O [M+H]$^+$ 306.9694, found 306.9700.

Preparation of 6-bromo-8-nitroquinolin-2(1H)-one 9 and 3,6-dibromo-8-nitroquinolin-2(1H)-one 10

8-Nitroquinolin-2(1H)-one (150 mg, 0.79 mmol, 1 equiv.) was dissolved into 25 mL of refluxing acetic acid saturated with sodium acetate. Then, 80 µL of bromine (1.58 mmol, 2 equiv.) were added dropwise and the reaction mixture was refluxed overnight. The reaction mixture was successively poured into ice, neutralized with K$_2$CO$_3$, extracted three times with dichloromethane (2 × 25 mL) and once with ethyl acetate (25 mL). The organic layer was washed with water, dried over anhydrous MgSO$_4$ and evaporated in vacuo. The crude residue was purified by chromatography on silica gel using dichloromethane/ethyl acetate (80/20) as an eluent. Compound 9 was isolated to yield a yellow solid (9%, 0.07 mmol, 20 mg) and compound 10 was isolated, after recrystallization in acetonitrile, to yield a yellow solid (33%, 0.26 mmol, 91 mg).

Compound 9 (C$_9$H$_5$BrN$_2$O$_3$): mp 230 °C, $^1$H NMR (400 MHz, CDCl$_3$) δ: 6.79 (dd, 1H, J = 9.7 and 2.0 Hz, H3), 7.72 (d, 1H, J = 9.7 Hz, H4), 8.00 (d, 1H, J = 2.2 Hz, H5), 8.60 (d, 1H, J = 2.2 Hz, H7), 11.19 (br s, 1H, NH). $^{13}$C NMR (150 MHz, CDCl$_3$) δ: 113.4 (C), 123.5 (C), 125.0 (CH), 130.3 (CH), 132.8
(C), 133.3 (C), 137.7 (CH), 138.7 (CH), 161.0 (C). HRMS (ESI-) calcd for C₉H₄BrN₂O₃ [M-H]⁻ 266.9405, found 266.9402.

Compound 10 (C₉H₄Br₂N₂O₃): mp 202 °C, ¹H NMR (400 MHz, CDCl₃) δ: 7.96 (d, 1H, J = 2.2, H₅), 8.16 (s, 1H, H₄), 8.63 (d, 1H, J = 2.2, H₇), 11.38 (br s, 1H, NH). ¹³C NMR (150 MHz, CDCl₃) δ: 114.1 (C), 121.3 (C), 123.5 (C), 130.4 (CH), 131.8 (C), 133.4 (C), 136.7 (CH), 139.8 (CH), 157.0 (C). HRMS (ESI-) calcd for C₉H₃Br₂N₂O₃ [M-H]⁻ 344.8510, found 344.8508.

Preparation of 3,6-dichloro-8-nitroquinolin-2(1H)-one 11
A solution of 15 mL of hydrochloric acid (37%) was added onto 100 mg of 8-nitroquinolin-2(1H)-one (0.53 mmol, 1 equiv.). The reaction mixture was then stirred at 100 °C before 280 mg of sodium chlorate (2.63 mmol, 5 equiv.) were added with caution (Cl₂ formation). After 24 h under reflux, the reaction mixture was left for 1 h under the hood to evacuate remaining Cl₂ vapor, and then was poured into ice, neutralized with K₂CO₃ and extracted three times with dichloromethane (3 × 50 mL). The organic layer was washed with water, dried over anhydrous Na₂SO₄ and evaporated in vacuo. The crude residue was purified by chromatography on silica gel using diethyl ether as an eluent, isolated and recrystallized in acetonitrile to yield a yellow solid (56%, 0.29 mmol, 76 mg).

Compound 11 (C₉H₅Cl₂N₂O₃): mp 197-198 °C, ¹H NMR (400 MHz, CDCl₃) δ: 7.83 (d, 1H, J = 2.3 Hz, H₅), 7.93 (s, 1H, H₄), 8.49 (d, 1H, J = 2.3 Hz, H₇), 11.42 (br s, 1H, NH). ¹³C NMR (100 MHz, CDCl₃) δ: 122.8 (C), 127.5 (CH), 127.7 (C), 130.6 (C), 130.9 (C), 133.3 (C), 133.9 (CH), 135.8 (CH), 157.0 (C). HRMS (DCI CH₄) calcd for C₉H₅Cl₂N₂O₃ [M+H⁺] 258.9677, found 258.9672.

Preparation of 6-bromo-3-chloro-8-nitroquinolin-2(1H)-one 12
A solution of 20 mL of hydrobromic acid (48%) was added onto 250 mg of 3-chloro-8-nitroquinolin-2(1H)-one (1.11 mmol, 1 equiv.). The reaction mixture was then stirred at 100°C before 700 mg of sodium bromate (4.4 mmol, 4 equiv.) were added with caution (Br₂ formation). After 24 h under reflux, the reaction mixture was left for 1 h under the hood to evacuate remaining Br₂ vapor, and then was poured into ice, neutralized with K₂CO₃ and extracted three times with dichloromethane (3 × 50 mL). The organic layer
was washed with water, dried over anhydrous MgSO\textsubscript{4} and evaporated in vacuo. The crude residue was purified by chromatography on silica gel using dichloromethane as an eluent. Compound 12 was isolated and recrystallized in isopropanol to yield a yellow solid (79%, 0.88 mmol, 266 mg).

Compound 12 (C\textsubscript{9}H\textsubscript{4}BrClN\textsubscript{2}O\textsubscript{3}): mp 232-233 °C, \textsuperscript{1}H NMR (400 MHz, CDCl\textsubscript{3}) δ: 7.93 (s, 1H, H4), 7.97 (d, 1H, J = 2.2 Hz, H5), 8.61 (d, 1H, J = 2.2 Hz, H7), 11.41 (br s, 1H, NH). \textsuperscript{13}C NMR (100 MHz, CDCl\textsubscript{3}) δ: 114.2 (C), 123.1 (C), 130.2 (CH), 130.5 (C), 131.2 (C), 133.3 (C), 135.7 (CH), 136.8 (CH), 157.0 (C). HRMS (DCI CH\textsubscript{4}) calcd pour C\textsubscript{9}H\textsubscript{4}BrClN\textsubscript{2}O\textsubscript{3} [M+H]\textsuperscript{+} 302.9172, found 302.9169.

Preparation of 6-bromo-3-(4-carboxyphenyl)-8-nitroquinolin-2(1\textsubscript{H})-one 13

In a sealed flask of 25 mL, 1 equiv. of 3,6-dibromo-8-nitroquinolin-2(1\textsubscript{H})-one 10 (0.86 mmol, 300 mg), 3 equiv. of cesium carbonate (2.6 mmol, 843 mg), 0.1 equiv. of Pd(PPh\textsubscript{3})\textsubscript{4} (0.086 mmol, 100 mg) and 1.2 equiv. of 4-(methoxycarbonyl)phenylboronic acid (1.03 mmol, 185 mg) were added. Under argon atmosphere, 10 mL of dimethoxyethane and 2 mL of water were then added. The reaction mixture was heated at 80 °C in a microwave reactor during 2 hours. The reaction mixture was poured into water, extracted twice with dichloromethane (2 × 50 mL) and twice with ethyl acetate (2 x 50 mL). The organic layer was washed with water, dried over anhydrous MgSO\textsubscript{4} and evaporated in vacuo. The crude residue was purified by chromatography on silica gel using dichloromethane/ethyl acetate (97/3) as an eluent. 6-bromo-3-(4-carboxymethylphenyl)-8-nitroquinolin-2(1\textsubscript{H})-one was isolated to yield a yellow solid (56%, 0.48 mmol, 195 mg). A solution of 40 mL of H\textsubscript{2}O/Ethanol (2/8) was added onto 95 mg of this compound (0.23 mmol, 1 equiv.). Then, 47 mg of NaOH (1.18 mmol, 5 equiv.) were added and the reaction mixture was stirred at 60°C for 2 h. The reaction mixture was then poured into water, neutralized with HCl 37% and extracted three times with ethyl acetate (3 × 25 mL). The combined organic layers were washed with a hydrochloric solution (pH = 1), dried over anhydrous MgSO\textsubscript{4} and evaporated in vacuo. The crude residue was washed with a sodium carbonate solution (pH = 9) and compound 13 was isolated as a pale brown solid (98%, 0.22 mmol, 88 mg). Global 2-step synthesis yield from 10= 55%.

Compound 13 (C\textsubscript{16}H\textsubscript{9}BrN\textsubscript{2}O\textsubscript{5}): Tdec. 300 °C, \textsuperscript{1}H NMR (400 MHz, DMSO-d\textsubscript{6}) δ: 7.90-8.06 (m, 4H, H2', H3', H5' and H6'), 8.40 (s, 1H, H4), 8.48 (d, 1H, J = 2.2 Hz, H5), 8.54 (d, 1H, J = 2.2 Hz, H7), 11.23 (br
s, 1H, NH), 13.08 (br s, 1H, COOH). $^{13}$C NMR (400 MHz, DMSO-d6) $\delta$: 112.8 (C), 124.00 (C), 129.3 (2xCH), 129.6 (2xCH), 129.7 (CH), 131.3 (C), 132.0 (C), 132.8 (C), 134.6 (C), 137.9 (CH), 138.1 (CH), 139.2 (C), 160.2 (C), 167.4 (C). HRMS (ESI-) calcd for C$_{16}$H$_3$BrN$_2$O$_5$ [M-H] - 386.9617, found 386.9620.

Preparation of 3-chloro-6-(3-hydroxyprop-1-ynyl)-8-nitroquinolin-2(1H)-one 14 and 3-chloro-6-(5-hydroxypent-1-ynyl)-8-nitroquinolin-2(1H)-one 15

In a sealed flask of 25 mL, 1 equiv. of 3-chloro-6-bromo-8-nitroquinolin-2(1H)-one 10 (0.98 mmol, 300 mg), 0.1 equiv. of Cul (0.098 mmol, 19 mg) and 0.1 equiv. of Pd(PPh$_3$)$_4$ (0.098 mmol, 113 mg) were added. Under argon atmosphere, anhydrous dimethoxyethane (10 mL), Et$_3$N (401 µL, 2.94 mmol, 3 equiv) and the appropriate alkyne (1.47 mmol, 1.5 equiv) were successively added. The reaction mixture was heated at 100 °C during 1 hour. The reaction mixture was poured into water, extracted twice with dichloromethane (2 x 50 mL) and twice with ethyl acetate (2 x 50 mL). The organic layer was washed with water, dried over anhydrous Na$_2$SO$_4$ and evaporated in vacuo. The crude residue was purified by chromatography on silica gel using dichloromethane/ethyl acetate (80/20) as an eluent and recrystallized to give compounds 14 and 15.

Compound 14 (C$_{12}$H$_7$ClN$_2$O$_4$) was recrystallized from isopropanol, as a beige solid in 15% yield (41 mg). Tdec. = 148 °C, $^1$H NMR (400 MHz, DMSO-d6) $\delta$: 4.35 (m, 3H), 8.18 (d, 1H, $J = 1.9$ Hz, H5), 8.31 (d, 1H, $J = 1.9$ Hz, H7), 8.48 (s, 1H, H4), 11.48 (br s, 1H, NH). $^{13}$C NMR (100 MHz, DMSO-d6) $\delta$: 49.8 (CH$_2$), 81.1 (C), 92.0 (C), 116.5 (C), 122.0 (CH), 128.0 (C), 129.8 (CH), 131.4 (C), 134.6 (C), 137.3 (CH), 137.8 (CH), 157.1 (C). HRMS (ESI+) calcd for C$_{12}$H$_8$ClN$_2$O$_4$ [M+H]$^+$ 279.0173, found 279.0185.

Compound 15 (C$_{14}$H$_{11}$ClN$_2$O$_4$) was recrystallized from isopropanol, as a yellow solid in 36% yield (108 mg). Tdec. = 176 °C, $^1$H NMR (400 MHz, DMSO-d6) $\delta$: 1.67-1.71 (m, 2H, CH$_2$), 2.50-2.54 (m, 2H, CH$_2$), 3.50-3.56 (q, 2H, $J = 17.6$ Hz, CH$_2$), 4.54-4.56 (t, 1H, $J = 10.3$ Hz, OH), 8.17 (d, 1H, $J = 1.9$ Hz, H5), 8.30 (d, 1H, $J = 1.9$ Hz, H7), 8.47 (s, 1H, H4), 11.47 (br s, 1H, NH). $^{13}$C NMR (100 MHz, DMSO-d6) $\delta$: 15.8 (CH$_2$), 31.7 (CH$_2$), 59.8 (CH$_2$), 77.8 (C), 93.1 (C), 117.4 (C), 122.0 (C), 127.9 (C), 129.85
(CH), 131.1 (C), 134.5 (C), 137.3 (CH), 137.75 (CH), 157.1 (C). HRMS (ESI+) calcd for C_{14}H_{12}ClN_{2}O_{4} [M+H]^+ 307.0486, found 307.0480.

**Electrochemistry**

Voltammetric measurements were carried out with a potentiostat Autolab PGSTAT100 (ECO Chemie, The Netherlands) controlled by GPES 4.09 software. Experiments were performed at room temperature in a homemade airtight three-electrode cell connected to a vacuum/argon line. The reference electrode consisted of a saturated calomel electrode (SCE) separated from the solution by a bridge compartment. The counter electrode was a platinum wire of approximately 1 cm² apparent surface. The working electrode was GC microdisk (1.0 mm of diameter – Biologic SAS). The supporting electrolyte tetrabutylammonium hexafluorophosphate (nBu₄N[PF₆], Fluka, 99% puriss electrochemical grade) and the solvent DMSO (Sigma-Aldrich puriss p. a. dried<0.02% water) were used as received and simply degassed under argon. The solutions used during the electrochemical studies were typically 10⁻³ M in compound and 0.1 M in supporting electrolyte. Before each measurement, the solutions were degassed by bubbling Ar and the working electrode was polished with a polishing machine (Presi P230). Under these experimental conditions employed in this work, the half-wave potential (E_{1/2}) of the ferrocene Fe⁺/Fc couple in DMSO was E_{1/2} = 0.45 V vs SCE. The redox potentials measured (V/SCE) correspond to the reversible one-electron reduction/oxidation of the redox couple nitro group/anion radical and were corrected versus the normal hydrogen electrode (+ 0.241 V).

**Biology**

*Antileishmanial activity on L. infantum axenic amastigotes.*[^1]

*L. infantum* promastigotes (MHOM/MA/67/ITMAP-263, CNR Leishmania, Montpellier, France, expressing luciferase activity) were cultivated in RPMI 1640 medium supplemented with 10% foetal calf serum (FCS), 2 mM L-glutamine and antibiotics (100 U/mL penicillin and 100 µg/mL streptomycin) and harvested in logarithmic phase of growth by centrifugation at 900 g for 10 min. The supernatant was removed carefully and was replaced by the same volume of RPMI 1640 complete medium at pH 5.4 and incubated for 24 h at 24 °C. The acidified promastigotes were then incubated for 24 h at 37 °C...
in a ventilated flask to transform promastigotes into axenic amastigotes. The amastigote stage was checked both by electron microscopy (short flagellum with small bulbous tip extending beyond a spherical cell body) and RT-PCR for confirming the overexpression of ATG8 and amastin genes in amastigotes, compared to promastigotes. The effects of the tested compounds on the growth of *L. infantum* axenic amastigotes were assessed as follows. *L. infantum* amastigotes were incubated at a density of $2 \times 10^6$ parasites/mL in sterile 96-well plates with various concentrations of compounds dissolved in DMSO (final concentration less than 0.5% v/v), in duplicate. Appropriate controls DMSO, amphotericin B, miltefosine and fexinidazole (reference drugs purchased from Sigma Aldrich) were added to each set of experiments. After a 48 h incubation period at 37 °C, each plate-well was then microscopically-examined to detect any precipitate formation. To estimate the luciferase activity of axenic amastigotes, 80 µL of each well were transferred to white 96-well plates, Steady Glow® reagent (Promega) was added according to manufacturer's instructions, and plates were incubated for 2 min. The luminescence was measured in Microbeta Luminescence Counter (PerkinElmer). Efficient concentration 50% (EC$_{50}$) was defined as the concentration of drug required to inhibit by 50% the metabolic activity of *L. infantum* amastigotes compared to control. EC$_{50}$ values were calculated by non-linear regression analysis processed on dose response curves, using TableCurve 2D V5 software. EC$_{50}$ values represent the mean of three independent experiments.

**Antileishmanial activity on *L. donovani* promastigotes NTR1 and NTR2 over-expressing strain.**

Cell lines and culture conditions: The clonal *Leishmania donovani* cell line LdBOB (derived from MHOM/SD/62/1S-CL2D) was grown as promastigotes at 26 °C in modified M199 media, as previously described.[2] LdBOB promastigotes overexpressing NTR1 (LinJ.05.0660) [3] and NTR2 (LinJ.12.0730) [4] were grown in the presence of nourseothricin (100 µg/mL). To examine the effects of test compounds on growth, triplicate promastigote cultures were seeded with $5 \times 10^4$ parasites/mL. Parasites were grown in 10 ml cultures in the presence of drug for 72 h, after which 200 µL aliquots of each culture were added to 96-well plates, 50 µM resazurin was added to each well and fluorescence (excitation of 528 nm and emission of 590 nm) measured after a further 4 h incubation [5]. Data were processed using GRAFIT (version 5.0.4; Erithacus software) and fitted to a 2-parameter equation, where the data are
corrected for background fluorescence, to obtain the concentration inhibiting growth by 50% (EC₅₀): In this equation [I] represents inhibitor concentration and m is the slope factor. Experiments were repeated at least two times and the data are presented as the weighted mean plus standard deviation.

\[
y = \frac{100}{1 + \left(\frac{[I]}{IC_{50}}\right)^m}
\]

Antitrypanosomal activity on T. brucei brucei trypomastigotes.

Assays were performed on Trypanosoma brucei brucei AnTat 1.9 strain (IMTA, Antwerpen, Belgium). It was cultured in MEM with Earle’s salts, supplemented according to the protocol of Baltz et al.\[^6\] with the following modifications, 0.5 mM mercaptoethanol (Sigma Aldrich\(^\text{®}\), France), 1.5 mM L-cysteine (Sigma Aldrich\(^\text{®}\)), 0.05 mM bathocuproïne sulfate (Sigma Aldrich\(^\text{®}\)) and 20% heat-inactivated horse serum (Gibco\(^\text{®}\), France), at 37°C in an atmosphere of 5% CO\(_2\). The parasites were incubated at an average density of 2000 parasites/well in sterile 96-wells plates (Mc2\(^\text{®}\), France) with various concentrations of compounds dissolved in DMSO (Sigma Aldrich\(^\text{®}\)), in duplicate. Reference drugs suramin, eflornithine, and fexinidazole (purchased from Sigma Aldrich, France and Fluorochem, UK) dissolved in NaCl 0.9% or DMSO, were added to each set of experiments. The effects of the tested compounds were assessed by the viability marker Alamar Blue\(^\text{®}\) (Fisher, France) assay described by Räz et al.\[^7\] After a 69 h incubation period at 37 °C, 10 µL of Alamar Blue\(^\text{®}\) was then added to each well, and the plates were incubated for 5h.\[^8\] The plates were read in a PerkinElmer ENSPIRE (Germany) microplate reader using an excitation wavelength of 530 nm and an emission wavelength of 590 nm. EC\(_{50}\) were calculated by nonlinear regression analysis processed on dose-response curves, using GraphPad Prism software (USA). EC\(_{50}\) was defined as the concentration of drug necessary to inhibit by 50% the viability of T. brucei brucei compared to the control. EC\(_{50}\) values were calculated from three independent experiments in duplicate.
Antitrypanosomal evaluation on the development of T. cruzi amastigotes

Vero cells (normal kidney epithelial cells of Cercopithecus aethiops) were obtained from the Virology Laboratory of the Pitié Salpêtrière Hospital (Paris, France). At late exponential growth phase, trypsin-treated Vero cells were subcultured every seven days in RPMI-1640 medium (Life technologies) supplemented with streptomycin/penicillin (Life technologies) and 5% heat-inactivated foetal bovine serum (FBS) (Life technologies). Subcultures were maintained at 37°C in a humidified atmosphere of 5% CO₂. CL Brener strain (collection number: MNHN-CEU-2016-0159) was a gift from Pr. P. Grellier of the Muséum National d’Histoire Naturelle (Paris, France). T. cruzi stocks were maintained by weekly passage in Vero cells. Infectious trypomastigotes were collected from culture supernatants.

Then, sterile, 06-well plates were seeded with exponentially growing Vero cells (40,000 cells per cm² in 2, 2 mL RPMI with serum per well) harvested from the preceding subcultures, were added to each well. After incubation at 37°C for 2 days in 5% CO₂ in air, the cells were infected with T. cruzi trypomastigotes in ratio 3:1 (parasites : host cells). After 24 hours, the non-infecting trypomastigotes removed by washing twice with HBSS buffer (without Ca²⁺ and Mg²⁺) and the chemical compounds in completed RPMI media were added immediately, to be tested to their inhibitory effects on parasite growth and development. Culture plates were incubated for an additional 120 h at 37°C with 5% CO₂. Three replicate wells for each condition were done. On days 5 and 6 post-infection, trypomastigotes were released from the cells. On day 6, the culture medium was removed and transferred to a centrifuge tube. Attached infected cells were washed with 5 mL of HBSS buffer. The culture medium and wash containing trypomastigotes were mixed and centrifuged at 1000 g for 15 min at room temperature. Subsequently, trypomastigotes re-suspended in 2 mL and counted in a haemocytometer (Kova cells) using a light microscope. For 50% effective concentration (EC₅₀) determinations, compounds were serially diluted 2 to 4-fold in RPMI media, with final assay concentrations ranging from 0,1 to 25 µM.

The 50% inhibiting concentrations (EC₅₀), defined as the drug concentration that resulted in a 50% reduction of trypomastigotes compared to the non-treated controls was estimated by non-linear regression analysis. EC₅₀ values represent the mean value calculated from two independent experiments that were performed in triplicate.
Antitrypanosomal activity on T. brucei trypomastigotes overexpressing the nitroreductase (NTR1).

Trypanosoma brucei bloodstream-form 'single marker' S427 (T7RPOL TETR NEO) and drug-resistant cell lines were cultured at 37°C in HMI9-T medium\(^9\) supplemented with 2.5 μg/mL G418 to maintain expression of T7 RNA polymerase and the tetracycline repressor protein. Bloodstream trypanosomes overexpressing the T. brucei nitroreductase (NTR1)\(^10\) were grown in medium supplemented with 2.5 μg/mL phleomycin and expression of NTR was induced by the addition of 1 μg/mL tetracycline. Cultures were initiated with 1 × 10\(^5\) cells ml\(^{-1}\) and sub-cultured when cell densities approached 1–2 (× 10\(^6\))/mL. In order to examine the effects of inhibitors on the growth of these parasites, triplicate cultures containing the inhibitor were seeded at 1 × 10\(^5\) trypanosomes/mL. Cells overexpressing NTR were induced with tetracycline 48 h prior to EC\(_{50}\) analysis. Cell densities were determined after culture for 72 h, as previously described\(^11\). EC\(_{50}\) values were determined using GraFit as described above.

Cytotoxic evaluation on HepG2 cell line.

The evaluation of the molecules cytotoxicity on the HepG2 (hepatocarcinoma cell line from ECACC purchased from Sigma-Aldrich, ref 85011430-1VL certificated without mycoplasma) was done according to the method of Mosman with slight modifications.\(^12\) Briefly, cells (1 × 10\(^5\) cells/mL) in 100 μL of complete medium, [Alpha MEM Eagle from PAN BIOTECH supplemented with 10% foetal bovine serum, 2 mM L-glutamine and antibiotics (100 U/mL penicillin and 100 μg/mL streptomycin)] were seeded into each well of 96-well plates and incubated at 37 °C and 5% CO\(_2\). After a 24 h incubation, 100 μL of medium with various product concentrations and appropriate controls were added and the plates were incubated for 72 h at 37 °C and 5% CO\(_2\). Each plate-well was then microscope-examined for detecting possible precipitate formation before the medium was aspirated from the wells. A MTT solution (100 μL, 0.5 mg/mL in Alpha MEM Eagle) was then added to each well. Cells were incubated for 2 h at 37 °C and 5% CO\(_2\). After this time, the MTT solution was removed and DMSO (100 μL) was added to dissolve the resulting formazan crystals. Plates were shaken vigorously (300 rpm) for 5 min. The absorbance was measured at 570 nm with a microplate spectrophotometer (Eon BioTek). DMSO was used as blank and doxorubicin (purchased from Sigma Aldrich) as positive control. CC\(_{50}\) were
calculated by non-linear regression analysis processed on dose response curves, using TableCurve 2D V5 software. CC₅₀ values represent the mean value calculated from three independent experiments.

Comet assay

The alkaline comet assay was used to detect DNA strand breaks and alkali-labile sites. Trypsinized HepG2 cells were embedded in 0.7% low-melting point agarose (Sigma “Low Gelling Temperature”) and laid on pre-cut sheets of polyester film (Gelbond® film) to perform minigel deposits as previously described[13]. Films were then placed in lysis solution (2.5 M NaCl, 0.1 M Na₂EDTA, 10 mM Tris, 1% Triton X-100, 10 % DMSO pH 10) for 18 h at 4 °C. Electrophoresis (with a solution which contained 0.3 M NaOH, 1 mM Na₂EDTA, pH > 13) was processed for 24 min in a tank with a power supply giving 28 V (resulting in 0.8 V/cm). After electrophoresis, films were immersed 2 × 5 min in PBS for neutralization, followed by fixation in 100% ethanol for 1.5 h and drying. After staining with SYBR® Gold (Life Technologies) at 10 000 × dilution for 20 min, films were observed at 20x magnification with an epifluorescence microscope equipped with an automated platform (Nikon NiE) and coupled to a camera (DS-Q1Mc) and the software Nikon NiS Element Advanced Research to automatically capture images. In these images, for each cell, the level of DNA damage was evaluated using a semi-automated scoring system, by measurement of the intensity of all tail pixels divided by the total intensity of all pixels in head and tail of comet, by means of the software “Lucia comet assay” (Laboratory Imaging, Prague Czech Republic). Fifty cells per deposit and two deposits per sample were analyzed. The median from these 100 values was calculated and named “% tail DNA”.

Parallel Artificial Membrane Permeability Assay (PAMPA)[14,15]

The PAMPA-BBB experiments were conducted using the Pampa Explorer Kit (Pion Inc) according to manufacturer's protocol. Briefly, each stock compound solution (20 mM in DMSO) were diluted in Prisma HT buffer pH 7.4 (Pion Inc) to 100 µM. 200 µL of this solution (n = 6) were added to donor plate (P/N 110243). BBB-1 Lipid (5 µL, P/N 110672) was used to coat the membrane filter of the acceptor plate (P/N 110243). Brain Sink Buffer (200 µL, P/N 110674) was added to each well of the acceptor plate. The sandwich was incubated at room temperature for 4h, without stirring. After the
incubation the UV-visible spectra were measured with the microplate reader (Tecan infinite M200), and
the permeability value (Pe) was calculated by the PAMPA Explorer software v.3.7 (pION) for each
compound. The corticosterone and the theophylline were used as references.

**Solubility determination at pH 7.4.**

Thermodynamic solubility at pH 7.4 of molecule 12 was determined according to the classical shake-
flask method (Organisation for Economic Cooperation and Development guideline n° 105) and a
miniaturized procedure. [16] Phosphate Buffer solutions (pH 7.4, 10 μM, ionic strength 50 mM) were
prepared from Na₂HPO₄, KH₂PO₄ and KCl (Sigma Aldrich, Saint Quentin Fallavier, France); 10 μL of
50 mM stock solution was added to 1.5 mL microtubes containing 990 mL buffer (n = 4). Tubes were
briefly sonicated and shacked by inversion during 24 h at room temperature. Then, microtubes were
centrifuged at 12,225×g for 5 min; 100 μL supernatant was mixed with 100 μL acetonitrile in a Greiner
UV microplate. Standard solutions were prepared extemporaneously diluting 25 mM DMSO stock
solutions at 0, 5 and 12.5 mM; 5 μL each working solution was diluted with 995 μL buffer and 100 μL
was then mixed in microplate with 100 μL acetonitrile to keep unchanged the final proportions of each
solvent in standard solutions and samples. Determination of solubility at pH 7.4 was made with a
Synergy 2 (Biotek, Colmar, France) microplate reader in spectrophotometric mode (230 to 450 nm)
from the specific $\lambda_{\text{max}}$ of each compound. The calibration curve obtained from the three standard
solutions of tested compounds at 0, 25, and 50 μM in a 50:50 (vol/vol) mixture of buffer with
acetonitrinile/DMSO (99:1; vol/vol). Calibration curves were linear with $R^2 > 0.99$.

**Microsomal stability protocol.**

The compounds and propranolol, used as reference, are incubated in duplicate (reaction volume of 0.5
mL) with female mouse microsomes (CD-1, 20 mg / ml, BD Gentest™) at 37 °C in a 50 mM phosphate
buffer, pH 7.4, in the presence of MgCl₂ (5 mM), NADP (1 mM), glucose-6-phosphate dehydrogenase
(0.4 U/mL) and glucose-6-phosphate (5 mM). For the estimation of the intrinsic clearance: 50 μL aliquot
at 0, 5, 10, 20, 30 and 40 min are collected and the reaction is stopped with 4 volumes of acetonitrile
(ACN) containing the internal standard. After centrifugation at 10000 g, 10 min, 4 °C, the supernatants
are kept at 4 °C for immediate analysis or placed at -80 °C in case of postponement of the analysis. Controls (t₀ and tₚ₀) in triplicate are prepared by incubation of the internal standard with microsomes denatured by acetonitrile. The LC-MS used for this study is a Waters® Acquity I-Class / Xevo TQD, equipped with a Waters® Acquity BEH C18 column, 50 x 2.1 mm, 1.7 μm. The mobile phases are (A) ammonium acetate 10 mM and (B) acetonitrile with 0.1% formic acid. The injection volume is 1 µL and the flow rate is 600 µL/min. The chromatographic analysis, total duration of 4 min, is made with the following gradient: 0 < t < 0.2 min, 2% (B); 0.2 < t < 2 min, linear increase to 98% (B); 2 < t < 2.5 min, 98% (B); 2.5 < t < 2.6 min, linear decrease to 2% (B); 2.6 < t < 4 min, 2% (B). Compound 8-bromo-6-chloro-3-nitro-2-(phenylsulfonylmethyl)imidazo[1,2-a]pyridine is used as internal standard. The quantification of each compound is obtained by converting the average of the ratios of the analyte/internal standard surfaces to the percentage of consumed product. The ratio of the control at t₀ corresponds to 0% of product consumed. The calculation of the half-life (t₁/₂) of each compound in the presence of microsomes is done according to the equation: \[ t_{\frac{1}{2}} = \frac{\ln(2)}{k} \]. Where k is the first-order degradation constant (the slope of the logarithm of compound concentration versus incubation time).

The intrinsic clearance in vitro (Clᵢᵣ expressed in µL/min/mg) is calculated according to the equation:

\[ Cl_{int} = \frac{dose}{AUC_\infty} \frac{1}{[microsomes]} \]

Where dose is the initial concentration of product in the sample, AUC_∞ is the area under the concentration-time curve extrapolated to infinity and [microsomes] is the microsome concentration expressed in mg/µL.

**Plasma protein binding procedure.**

The plasma doped with the tested compound is incubated at 37 °C in triplicate in one of the compartments of the insert, the other compartment containing a phosphate buffer solution at pH 7.2. After stirring for 4 h at 300 rpm, a 25 µL aliquot of each compartment is taken and diluted; the dilution solution is adapted to obtain an identical matrix for all the compartments after dilution. In parallel, the reprocessing of a plasma doped but not incubated will allow to evaluate the recovery of the study. The LC-MS used for this study is a Waters® Acquity I-Class / Xevo TQD, equipped with a Waters® Acquity
BEH C18 column, 50 × 2.1 mm, 1.7 µm. The mobile phases are (A) ammonium acetate 10 mM and (B) acetonitrile with 0.1% formic acid. The injection volume is 1 µL and the flow rate is 600 µL/min. The chromatographic analysis, total duration of 4 min, is made with the following gradient: 0 < t < 0.2 min, 2% (B); 0.2 < t < 2 min, linear increase to 98% (B); 2 < t < 2.5 min, 98% (B); 2.5 < t < 2.6 min, linear decrease to 2% (B); 2.6 < t < 4 min, 2% (B). Carbamazepine, oxazepam, warfarine and diclofenac are used as reference drugs and Propranolol is used as internal standard. The unbound fraction (fu) is calculated according to the following formula: \[ f_u = \frac{A_{\text{Plasma, 4h}} - A_{\text{PBS, 4h}}}{A_{\text{Plasma, 4h}}} \times 100. \]

The percentage of recovery is calculated according to the following formula: \[ \% \text{Recovery} = \frac{(V_{\text{PBS}} \times A_{\text{PBS, 4h}}) + (V_{\text{Plasma}} \times A_{\text{Plasma, 4h}})}{(V_{\text{Plasma}} \times A_{\text{Plasma, 0h}})}. \]

Where A is the ratio of the area under peak of the studied molecule and the area under peak of the internal standard (propranolol 200 nM). V is the volume of solution present in the compartments (VPBS = 350 µL and Vplasma = 200 µL).

**In vivo analysis**

Female Swiss mice of 8 weeks (weight 30-32 g) are used. All animals were kept under the same conditions according to laboratory animal care guidelines (European convention SPE123), and all protocol are approved by the ethical committee and the Ministry of Higher Education, Research and Innovation with the agreement number APAFIS#19730-2019031215178087 v1.

Four mice received 50 µL of the 12 suspension by oral route at 25 mg/kg (the tolerated dose). One hundred microliters of blood were taken from tail and collected into micro tubes with heparin at 0.5, 1, 3, 6, 9, 12, and 24h after administration. Blood samples were stored frozen until required for assay.

**Sample preparation for spectrometry analysis**

Megazol was used like the internal standard (IS). LC-MS Optima grade Acetonitrile (ACN) and Methanol (MeOH), acetic acid and formic acid (FA) were purchased from Fisher Scientific. Ready-to-use QuEChERS salts (6 g MgSO4/1.5 g NaCl/1.5 g sodium citrate dihydrate/750mg sodium citrate sesquihydrate) were supplied by VWR.
200 µl of ACN containing megazol (IS) at a concentration of 625 ng/ml were added to 100 µl blood samples. The mixture was vortexed during 30 sec. After 10 min, 40 mg of QuEChERS salts were added. Samples were briefly vortexed and centrifuged at 16,000 g for 10 min. Ten microliters of the upper layer was directly transferred in an injection vial before being diluted (1/10; v/v) in a 0.1 % formic acid in water. Finally, 5µL was injected in the LC-MS-MS system.

Calibrations standards (8 levels, from 10 to 1,000ng/ml) and quality controls (QC) (75 and 625 ng/ml) were obtained by adding appropriate 20X working standard solutions in blank whole blood. [17, 18]

**LC-MS/MS conditions**

The chromatographic system consisted in two Shimadzu LC-30 AD pumps (NexeraX2), a CTO 20AC oven, and a SIL-30AC autosampler (Shimadzu, Marne-la-Vallée, France). Chromatographic separation was performed using a EC-C8 column (Poroshell 120, 2.1 mm x 75 mm, 2.7 µM; Agilent) at a flow rate of 0.25ml/min using a gradient of 0.1% acetic acid in water (A) and 0.1% acetic acid in MeOH/ACN 50:50 (B) programmed as follows: 0.0–0.1, 20% (B); 0.1–1.0, 20 to 70% (B); 1.0–4.0, 70% to 100% (B); 4.0–5.5, 100% (B); 5.5–6.0, 100 to 20% (B); and 6.0–8.0 column equilibration with 20% (B). Oven temperature was set at 60 °C.

A Shimadzu 8060 triple quadrupole mass spectrometer was used in the negative electrospray ionization mode. The main common parameter settings were as follows: interface voltage, 1.5kV; nebulizing gas flow, 3 L/min; heating gas flow, 10 L/min; interface temperature, 300°C; desolvatation line (DL) temperature, 250°C; heat block temperature, 400°C; and drying gas flow, 10 L/min. Multiple-reaction monitoring (MRM) transitions and specific parameters are presented in Table 1. All parameters (collision energy, Q1/Q3 pre-bias) were optimized from standard flow injection analysis. Dwell time was set at 100ms per transition.
Table 1: LC retention time (RT) and selected MS/MS detection conditions

| Compounds          | Retention time (min) | Precursor ion m/z | Q1 pre-bias (V) | Product ion Quantitation m/z | Collision energy (V) | Confirmation m/z | Q3 pre-bias (V) | Collision energy (V) | Q3 pre-bias (V) |

Validation procedure for whole blood

Validation protocol and the set of acceptance criteria were as follows:

- Linearity: Calibration curve was generated by plotting the peak area ratios (analyte/internal standard) vs the expected concentration. Linearity of the calibration curve was evaluated by a quadratic regression analysis using a 1/x² weighting. A value greater than 0.99 was expected for the coefficient of determination ($r^2$).

- Precision and accuracy of the method were assessed at lower limit of quantitation (LLOQ; 10ng/ml) and at the two quality control concentrations (75 and 625 ng/ml). Precision is calculated as the coefficient of variation (CV%) within a single run (intra-assay; n=5) and between different assays (inter-assay; n=5), and accuracy is the percentage of deviation between nominal and found concentration with the established calibration curve. Acceptance criteria were intra-assay and inter-assay precision (CV%) and an accuracy (bias) less than 20 %.

- The lower limit of quantification (LLOQ) was estimated to be the minimal concentration with accuracy and precision within +/-20%. The lower limit of detection (LLOD) was calculated based on a signal-to-noise ratio >3.
- Extraction recoveries were determined by comparing the LLOQ and the quality controls samples \(n=5\) with their extracted blank whole blood counterparts spiked at the correct concentration after extraction \(n=3\). CV\% in the extraction recovery had to be less than 20\%.

- The effect of dilution was investigated on samples spiked at 5-fold \((5,000 \text{ ng/ml})\) and 20-fold \((20,000 \text{ ng/ml})\) of ULOQ then re-analyzed after ten- and forty-fold dilutions. Precision CV and bias were set less than 20\% to successfully validate.

- The absence of carryover was checked by injecting blank samples just after the analysis of the most concentrated sample \((1,000 \text{ ng/ml})\).

4. Comet assay

![Image of Comet assay graph]

**Figure S15.** Comet assay on HepG2 cells for compound 12. Positive control: 1 mM methylmethanesulfonate (MMS). Results are mean ± SD of three independent experiments. Statistical analysis was performed by one-way ANOVA followed by Dunnetts’s multiple comparison for each time (***P < 0.001 versus control).

5. In vivo pharmacokinetic study

Following the developed extraction procedure, the preparation of a classical batch that includes 9 calibration standards, 2 internal quality controls, and 20 whole blood samples required less than 1.5 hour. The chromatographic separation of the compound and its internal standard was obtained in 8 min. As presented in Figure S16, acceptance criteria were obtained for both the intra-assay and the inter-assay precision and accuracy. The CV% values in the extraction recovery were also less than 20%. Using quadratic regression with a $1/x^2$ weighting, the coefficients of determination of the calibration curves between 10 and 1,000 ng/ml were higher than 0.99. According to these results, the LLOQ was considered to be 10 ng/ml and the LLOD was determined at 5 ng/ml.
**Figure S16:** Main parameters of the validation protocol

|                  | LLOQ   | LQC  | HQC  | 5*ULOQ | 20*ULOQ |
|------------------|--------|------|------|--------|---------|
| *Coefficient of determination (r²)* | 0.9950 ± 0.0051 |
| Recovery (%) (%CV) (*n=3*) | 105.4% (17.7%) | 102.1% (2.7%) | 92.7% (5.9%) |
| **Intra-assay (*n=5*)** | | | | | |
| Mean ± SD (ng/ml) | 9.47 ± 1.44 | 79.35 ± 2.11 | 622.04 ± 39.87 |
| Accuracy | 94.7% | 105.8% | 99.5% |
| CV% | 15.2% | 2.7% | 6.4% |
| **Inter-assay (*n=5*)** | | | | | |
| Mean ± SD (ng/ml) | 10.21 ± 0.86 | 76.42 ± 6.41 | 652.54 ± 33.45 |
| Accuracy | 102.1% | 101.9% | 104.4% |
| CV% | 8.4% | 8.4% | 5.1% |
| **dilution test (*n=3*)** | | | | | |
| ten-fold dilution | Mean ± SD (ng/ml) | 3,773.3 ± 721.3 | 75.5% (19.1%) |
| Accuracy (%CV) | 123495 ± 31693 | 0.00768 ± 0.0021 |
| forty-fold dilution | Mean ± SD (ng/ml) | 5,257.1 ± 163.3 | 21,432.4 ± 1,004.0 |
| Accuracy (%CV) | 105.1% (3.1%) | 107.2% (4.7%) |

**Figure S17.** Pharmacokinetic parameters of hit compound 12 in whole blood of mouse after oral administration at 25 mg/kg (*n = 4*)

|                  | Cmax (ng/mL) ± SD | Tmax (h) ± SD | T1/2 (h) ± SD | AUC0-inf (ng.h/mL) ± SD | Clairance (mL/h) ± SD |
|------------------|-------------------|---------------|--------------|------------------------|----------------------|
| 12               | 17428 ± 8337      | 1.5 ± 1       | 2.87 ± 0.95  | 123495 ± 31693         | 0.00768 ± 0.0021     |
6. Cyclic voltammograms

Figure S18: Cyclic voltammetry of compound 7 ($10^{-3}$ mol L$^{-1}$) in DMSO + 0.1 mol L$^{-1}$ of (n-Bu$_4$ N)[PF$_6$] on GC microdisk (r = 0.5mm) at room temperature. Scan rate: 0.2 V s$^{-1}$.

Figure S19: Cyclic voltammetry of compound 12 ($10^{-3}$ mol L$^{-1}$) in DMSO + 0.1 mol L$^{-1}$ of (n-Bu$_4$ N)[PF$_6$] on GC microdisk (r = 0.5mm) at room temperature. Scan rate: 0.2 V s$^{-1}$.
Figure S20: Cyclic voltammetry of compound 13 \((10^{-3} \text{ mol L}^{-1})\) in DMSO + 0.1 mol L\(^{-1}\) of (n-Bu\(_4\) N)[PF\(_6\)] on GC microdisk \((r = 0.5\text{ mm})\) at room temperature. Scan rate: 0.2 V s\(^{-1}\).
