Abstract

We develop a theory of graph algebras over general fields. This is modeled after the theory developed by Freedman, Lovász and Schrijver in [19] for connection matrices, in the study of graph homomorphism functions over real edge weight and positive vertex weight. We introduce connection tensors for graph properties. This notion naturally generalizes the concept of connection matrices. It is shown that counting perfect matchings, and a host of other graph properties naturally defined as Holant problems (edge models), cannot be expressed by graph homomorphism functions over the complex numbers (or even more general fields). Our necessary and sufficient condition in terms of connection tensors is a simple exponential rank bound. It shows that positive semidefiniteness is not needed in the more general setting.
1 Introduction

Many graph properties can be described in the general framework called graph homomorphisms. Suppose $G$ and $H$ are two graphs. A mapping from the vertex set $V(G)$ to the vertex set $V(H)$ is a graph homomorphism if every edge $\{u, v\}$ of $G$ is mapped to an edge (or a loop) of $H$. For example, if $H$ consists of two vertices $\{0, 1\}$ with one edge between them and a loop at 0, then a vertex map $\phi : V(G) \to \{0, 1\}$ is a graph homomorphism iff $\phi^{-1}(1)$ is an independent set of $G$. As another example, if $H = K_q$ is a clique on $q$ vertices (no loops), then a vertex map $\phi : V(G) \to \{1, \ldots, q\}$ is a graph homomorphism iff $\phi$ is a proper vertex coloring of $G$ using at most $q$ colors.

A more quantitative notion is the so-called partition function associated with graph homomorphisms. The idea is that we can consider a fixed $H$ with vertex weights and edge weights, and aggregate all graph homomorphisms from $G$ to $H$, in a sum-of-product expression called the partition function. This expression is invariant under graph isomorphisms, thus expressing a graph property of $G$. This is a weighted counting version of the underlying concept.

More concretely, if each vertex $i \in V(H)$ has weight $\alpha_i$ and each edge $\{i, j\}$ of $H$ has weight $\beta_{i,j}$ (non-edge has weight 0), then the partition function $Z_H(\cdot)$ determined by $H$ is

$$Z_H(G) = \text{hom}(G, H) = \sum_{\phi : V(G) \to V(H)} \prod_{u \in V(G)} \alpha_{\phi(u)} \prod_{\{v, w\} \in E(G)} \beta_{\phi(v), \phi(w)}. \quad (1.1)$$

The partition functions of graph homomorphisms can express a broad class of weighted counting problems. Historically these partition functions also arise in statistical physics, where they play a fundamental role. In classical physics the vertex and edge weights are typically (nonnegative) real numbers, but in quantum theory they are complex numbers. But even in classical physics, sometimes a generalization to complex numbers allows a theoretically pleasing treatment. E.g., Baxter generalized the parameters to complex values to develop the “commuting transfer matrix” for the six-vertex model [1]. The book [21] (section 2.5.2) treats the Hamiltonian of a one-dimensional spin chain as an extension of the Hamiltonian of a six-vertex model with complex Boltzmann weights.

Another source of fascination with these objects comes from the classification program for counting problems in complexity theory. In recent years many far-reaching classification theorems have been proved classifying every problem in a broad class of counting problems as being either computable in polynomial time, or being $\#P$-hard. This has been proved for graph homomorphisms (GH) [16, 17, 2, 31, 22, 20, 7], for counting constraint satisfaction problems ($\#CSP$) [4, 3, 18, 6], and for Holant problems [13, 23, 11]. These theorems are called complexity dichotomies. If we consider problem instances restricted to planar graphs and variables to take Boolean values, there is usually a trichotomy, where every problem is either (1) computable in polynomial time, or (2) $\#P$-hard on general graphs but computable in polynomial time for planar graphs, or (3) $\#P$-hard on planar graphs. Counting perfect matchings, including weighted versions, is one such problem that belongs to type (2). The planar tractability of counting perfect matchings is by Kasteleyn’s algorithm (a.k.a. FKT-algorithm) [25, 26, 30]. Valiant introduced holographic algorithms to significantly extend the reach of this methodology [33, 32, 12]. It is proved that for all $\#CSP$ where variables are Boolean (but constraint functions can take complex values), the methodology of holographic algorithms is universal [8]. More precisely, we can prove that (A) the three-way classification above holds, and (B) the problems that belong to type (2) are precisely those that can be captured by this single algorithmic approach, namely a holographic reduction to Kasteleyn’s algorithm.

$\#CSP$ are “vertex models” where vertices are variables, and constraints are placed on subsets
of these variables. The partition function of GH can be viewed as a special case of \#CSP where each constraint is a binary function (and for undirected graphs, a symmetric binary function).

In contrast to vertex models, one can consider “edge models” where each edge is a variable, and constraint functions are placed at each vertex. This is called a Holant problem \(^*\). Counting perfect matchings is a Holant problem where the constraint function at each vertex is the \textsc{Exact-One} function. Counting all matchings is a Holant problem with the \textsc{At-Most-One} constraint. Other Holant problems include counting edge colorings, or vertex disjoint cycle covers. Many problems in statistical physics, such as (weighted) orientation problems, ice models, six-vertex models etc. are all naturally expressible as Holant problems.

It has been proved \([11, 9]\) that for Holant problems defined by an arbitrary set of complex-valued symmetric constraint functions on Boolean variables, (A) the three-way classification above holds, but (B) holographic reductions to Kasteleyn’s algorithm is \textit{not} universal for type (2); there is an additional class of planar P-time computable problems; these, together with holographic reductions to Kasteleyn’s algorithm, constitute a complete algorithmic repertoire for this class. (It is open whether this also holds for non-symmetric constraint functions.)

But this should strike the readers as somewhat ironic. Counting perfect matchings \textit{is} the problem that Kasteleyn’s algorithm solves for planar graphs. However it is proved universal for type (2) for vertex models but \textit{not} for edge models, and yet it is a \textit{quintessential} Holant problem. It is most naturally expressed in the edge model. It is \textit{not} naturally expressed as a vertex model.

Or can it?

Freedman, Lovász and Schrijver \([19]\) proved that counting perfect matchings cannot be expressed as the partition function of GH; however their proof restricts to a definition of partition functions with positive vertex weights and real valued edge weights. More importantly they give a characterization for a graph property to be \textit{expressible} as such a partition function of GH.

Their characterization consists of two conditions on a \textit{connection matrix}: a rank condition and a positive semidefiniteness condition. But when we move from \(\mathbb{R}\) to the complex field \(\mathbb{C}\), this positive semidefiniteness condition breaks down. At a high level, a succinct reason is that for complex matrices \(M\), it is \textit{not} true that \(M^T M\) is positive semidefinite. However, partition functions of GH with complex weights are interesting, and natural in the quantum setting. More intrinsically (but less obviously), even if one is dealing with counting problems defined by real weights, complex matrices are essential as holographic transformations. For example, the matrix \(Z = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ -1 & i \end{bmatrix}\) is one of the most important holographic transformations \([5, 9]\) in dealing with orientation problems such as the six-vertex model, even when all given weights are real. Note that \(Z\) transforms the binary \textsc{Equality} function to \textsc{Disequality}, which is expressible in the form of signature matrices as: \(Z^T I Z = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}\). Thus it remained an open problem whether counting perfect matchings, and other similar problems naturally expressible as Holant problems (edge models), can be expressed as partition functions of GH when complex weights are allowed.

In this paper we resolve this question. We define the notion of a \textit{connection tensor}. Then we give an alternative, tensor theoretic characterization of when a graph parameter can be expressed as GH over \textit{any} field. We show that there is \textit{only one} condition, which is both necessary and sufficient for a graph parameter to be expressible by GH, and that is a simple exponential bound on the rank of the connection tensor. Positive semidefiniteness is not required (and would not be

\(^*\)Balázs Szegedy \([29]\) studied “edge coloring models” which are equivalent to a special case of Holant problems where at each vertex of degree \(d\) a single symmetric function of arity \(d\) is provided. In general Holant problems allow different (possibly non-symmetric) constraint functions from a set assigned at vertices; see \([5]\).
meaningful for a general field.)

This characterization is purely algebraic. As a consequence we show that counting perfect matchings is not expressible as partition functions of GH over an arbitrary field. We also prove the same inexpressibility for several other naturally defined Holant problems. Over bounded degree graphs, we prove a sharp threshold for the domain size \(|V(H)|\) for expressibility, using holographic transformations. While we dispense with their positive semidefiniteness condition, the paper [19] is an inspiration for this work from which we borrow many definitions and ideas.

However, the possibility that vertex weights can cancel, in particular the sum of all vertex weights can be 0, does create a significant technical obstacle, and we have to introduce some consequential changes to their proof. In addition to the algebras of quantum graphs \(G(S)\), we define a second type of algebras of quantum graphs \(G\subseteq(S)\) where \(S \subseteq \mathbb{Z}_+\) is a finite set of labels. In \(G(S)\) the generators are precisely \(S\)-labeled graphs, whereas in \(G\subseteq(S)\) their label sets can be arbitrary subsets of \(S\). We need to do this because the normalization argument from [19] fails (precisely because the sum of all vertex weights can be 0). One technical step involves correctly defining the notion of a projection from one quotient algebra to another, \(\hat{\pi}_S : \hat{G} \to \hat{G}\subseteq(S)\). It must be onto \(\hat{G}\subseteq(S)\) which is not in general the same as \(\hat{G}(S)\), the corresponding quotient algebra without the normalization. (In [19] this notion of \(G\subseteq(S)\) was not needed.) After the appropriate algebraic structures are all in place, now somewhat more elaborate than that of [19], we are able to establish our algebraic characterization of expressibility of a graph property as GH.

An outline of this paper is as follows. Our main theorems are Theorem 3.3 and Theorem 3.4. To prove these theorems we need a proper algebraic setting, and these are certain infinite-dimensional algebras, which are vector spaces endowed with a multiplication. These algebras are infinite-dimensional because we wish to account for all finite labeled graphs in one structure. Being infinite-dimensional introduces some technical complications. In Section 2 we include some basic notions, mainly regarding tensor spaces. In the context of this paper the coordinates of these infinite-dimensional vector spaces represent partially labeled graphs in the algebra \(G(S)\) or \(G\subseteq(S)\) (to be defined in Section 5). In Section 3, we introduce the basic definitions of graph algebras and connection tensors of a graph parameter. In Section 4, we show how the tensor theoretic characterization can be used to prove that some graph properties cannot be expressed as GH over any field. The main proof starts in Section 5. In subsection 5.1, we define the monoid of partially labeled graphs and the algebra of quantum graphs in more detail. We define the algebras of quantum graphs \(G(S)\) and \(G\subseteq(S)\), the ideals \(K_S\) and \(K\subseteq(S)\), and the respective quotients \(\hat{G}(S)\) and \(\hat{G}\subseteq(S)\). We also introduce and prove the correctness of the definition of the aforementioned projection \(\hat{\pi}_S : \hat{G} \to \hat{G}\subseteq(S)\), which arises from the linear map \(\pi_S : G \to G(S)\). As said before, the possibility that the vertex weights sum to 0 does not allow us to perform the corresponding normalization step, and we cannot just simply repeat the proofs from [19] without extending all the definitions systematically. With all the groundwork set, we may finally proceed to the main proof. We show the existence of the basis of idempotents in the quotient algebras \(\hat{G}(S)\) for finite \(S \subseteq \mathbb{Z}_+\) by constructing an isomorphism onto \(\mathbb{F}^r\) for some \(r\) (a composition of two isomorphisms, see Lemma 5.12 and Corollary 5.13) thereby bounding their dimensions as well. After that we are able to proceed similarly to Section 4 from [19], modifying the original proofs as needed.

Table 1 lists the main concepts and sets used in the paper.
2 Some Basic Concepts

In this paper \( \mathbb{F} \) denotes an arbitrary field, also viewed as a one-dimensional vector space over \( \mathbb{F} \). The set \( \mathbb{F}^I \) consists of tuples indexed by \( I \). We let \( \mathbb{Z}_{>0} \) denote the set of positive integer numbers. For any integer \( k \geq 0 \), let \( [k] = \{1, \ldots, k\} \). In particular, \( [0] = \emptyset \). For finite \( I = [n] \) we write \( \mathbb{F}^n \). By operations on components \( \mathbb{F}^I \) is an algebra (vector space and a ring). By convention \( \mathbb{F}^0 = \mathbb{F}^\emptyset = \{0\} \), and \( 0^0 = 1 \) in \( \mathbb{Z}, \mathbb{F} \), etc. We use \( \bigcup \) to denote disjoint union. In subsection 2.1 we briefly state some concepts and results. A more detailed account is given in Section 8 as an appendix.

2.1 Multilinear algebra

We assume that the reader is familiar with tensors. A main feature in this paper is that we deal with infinite dimensional spaces and their duals; and this infinite dimensionality causes technical complications. E.g., multilinear functions on \( \mathbb{F}^I \) is an algebra (vector space and a ring). By convention \( \mathbb{F}^0 = \mathbb{F}^\emptyset = \{0\} \), and \( 0^0 = 1 \) in \( \mathbb{Z}, \mathbb{F} \), etc. We use \( \bigcup \) to denote disjoint union. In subsection 2.1 we briefly state some concepts and results. A more detailed account is given in Section 8 as an appendix.

Let \( f \in (\mathbb{F}^V)^* \) be such that \( f(e_i \otimes e_j) = \delta_{ij} \), which is 1 if \( i = j \) and 0 otherwise. Then there is no tensor \( T \in (V^*)^{\otimes 2} \) that embeds as \( f \). Indeed, any \( T \in (V^*)^{\otimes 2} \) is, by definition, a finite sum \( T = \sum_{1 \leq k < n} c_k f_k \otimes g_k \). If \( T \) were to embed as \( f \), then consider the \( n \times n \) matrix where the \( (i, j) \) entry is \( f(e_i \otimes e_j) \), which is the identity matrix \( I_n \) of rank \( n \). However \( T(e_i \otimes e_j) = \sum_{1 \leq k < n} c_k f_k(e_i) \cdot g_k(e_j) \), and so the matrix for the embedded \( T \) has rank \( n \), being a sum of \( n - 1 \) matrices of rank \( \leq 1 \).

For any symmetric tensor \( A \in \text{Sym}^n(V) \) we define the symmetric rank of \( A \) to be the least \( r \geq 0 \) for which \( A \) can be expressed as

\[
A = \sum_{i=1}^r \lambda_i \nu_i^\otimes n, \quad \lambda_i \in \mathbb{F}, \nu_i \in V,
\]

and we denote it by \( \text{rk}_\text{S}(A) \). If there is no such decomposition we define \( \text{rk}_\text{S}(A) = \infty \). If \( \text{rk}_\text{S}(A) < \infty \)

| \( \mathbb{I} \cup \mathbb{K}, \mathbb{K}^I, \text{Sym}^n(\mathbb{F}^I), \text{rk}_\text{S}(T(f, k, n)) \) |
| \( \mathbb{P} \mathbb{L} \mathbb{G}, \mathbb{P} \mathbb{L} \mathbb{G} \subseteq (S), \mathbb{P} \mathbb{L} \mathbb{G} (S), \mathbb{P} \mathbb{L} \mathbb{G} [k] (= \mathbb{P} \mathbb{L} \mathbb{G} ([k])) \) |
| \( \mathbb{G}, \mathbb{G} \subseteq (S), \mathbb{G} (S), \mathbb{G}[k] (= \mathbb{G} ([k])) \) |
| \( \mathbb{K}, \mathbb{K} \subseteq S, \mathbb{K} S, \mathbb{K} [k] \) |
| \( \tilde{\mathbb{G}}, \tilde{\mathbb{G}} \subseteq (S), \tilde{\mathbb{G}} (S), \tilde{\mathbb{G}}[k] (= \tilde{\mathbb{G}} ([k])) \) |
| \( \mathbb{G}_\subseteq (S), \tilde{\mathbb{G}}(S), \tilde{\mathbb{G}}[k] (= \tilde{\mathbb{G}} ([k])) \) |
| \( \pi_S: \mathbb{G} \to \mathbb{G}_\subseteq (S), \tilde{\pi}_S: \tilde{\mathbb{G}} \to \tilde{\mathbb{G}}_\subseteq (S) \) |

Table 1: Main concepts and sets used in the paper.
then in any such expression of \( A \) as a sum of \( \text{rk}_{\mathbb{F}}(A) \) terms all \( \lambda_i \neq 0 \), all \( \mathbf{v}_i \neq 0 \) and are pairwise linearly independent. In subsection 8.2 we show that if \( \mathbb{F} \) is infinite, then \( \text{rk}_{\mathbb{F}}(A) < \infty \) for all \( A \in \text{Sym}^n(V) \). We state some facts below; proofs can be found in the Appendix (Section 8).

**Lemma 2.1.** The vectors \( \mathbf{x}_1, \ldots, \mathbf{x}_r \in \mathbb{F}^{\mathcal{I}} \) are linearly independent iff in the \( r \times \mathcal{I} \) matrix formed by \( \mathbf{x}_1, \ldots, \mathbf{x}_r \) as rows there exists a nonzero \( r \times r \) minor.

For \( \mathbf{x} = (x_i)_{i \in \mathcal{I}} \in \mathbb{F}^{\mathcal{I}} \) and \( h = (h_i)_{i \in \mathcal{I}} \in \bigoplus_{\mathcal{I}} \mathbb{F} \) (in a direct sum, only finitely many \( h_i \) are zero), we denote their dot product by \( \mathbf{x}(h) = \sum_{i \in \mathcal{I}} x_i h_i \in \mathbb{F} \). (In general the dot product for \( \mathbf{x}, \mathbf{y} \in \mathbb{F}^{\mathcal{I}} \) is not defined.)

**Lemma 2.2.** Let \( \mathbf{x}_1, \ldots, \mathbf{x}_r \in \mathbb{F}^{\mathcal{I}} \) be linearly independent. Then there exist \( h_1, \ldots, h_r \in \bigoplus_{\mathcal{I}} \mathbb{F} \) dual to \( \mathbf{x}_1, \ldots, \mathbf{x}_r \), i.e., \( \mathbf{x}_i(h_j) = \delta_{ij}, 1 \leq i, j \leq r \).

**Lemma 2.3.** Let \( \mathbf{x}_1, \ldots, \mathbf{x}_r \in \mathbb{F}^{\mathcal{I}} \). Consider the linear map \( \Phi : \bigoplus_{\mathcal{I}} \mathbb{F} \to \mathbb{F}^r, h \mapsto (\mathbf{x}_1(h), \ldots, \mathbf{x}_r(h)). \) Then \( \dim(\bigoplus_{\mathcal{I}} \mathbb{F}/\ker \Phi) = \dim \text{span}\{\mathbf{x}_i\}_{i=1}^r \).

**Lemma 2.4.** Let \( r \geq 0 \), and let \( \mathbf{x}_1, \ldots, \mathbf{x}_r \in \mathbb{F}^{\mathcal{I}} \) be \( r \) linearly independent vectors and \( a_1, \ldots, a_r \in \mathbb{F} \setminus \{0\} \). Then for any integer \( n \geq 2 \), the symmetric tensor

\[
A = \sum_{i=1}^r a_i x_i^\otimes n \in \text{Sym}^n(\mathbb{F}^{\mathcal{I}})
\]

has \( \text{rk}_{\mathbb{F}}(A) = r \). For \( n \geq 3 \), any expression of \( A \) as \( \sum_{i=1}^r b_i y_i^\otimes n \) is a permutation of the sum in (2.1).

**Lemma 2.5.** Let \( r \geq 0 \), and let \( \mathbf{x}_1, \ldots, \mathbf{x}_r \in \mathbb{F}^{\mathcal{I}} \) be \( r \) nonzero pairwise linearly independent vectors. Then for any nonnegative integer \( n \geq r - 1 \), the rank-1 symmetric tensors

\[
\mathbf{x}_1^\otimes n, \ldots, \mathbf{x}_r^\otimes n \in \text{Sym}^n(\mathbb{F}^{\mathcal{I}})
\]

are linearly independent.

### 2.2 Weighted graph homomorphisms

We recap the notion of weighted graph homomorphisms [19], but state it for an arbitrary field \( \mathbb{F} \).

An \( (\mathbb{F}) \)-**weighted graph** \( H \) is a graph with a weight \( \alpha_H(i) \in \mathbb{F} \setminus \{0\} \) associated with each node \( i \) and a weight \( \beta_H(i,j) \in \mathbb{F} \) associated with each edge \( ij \). For undirected \( \mathbf{G,H} \), we assume \( \beta_H(i,j) = \beta_H(j,i) \).

Let \( G \) be an unweighted graph (with possible multiple edges, but no loops) and \( H \) a weighted graph (with possible loops, but no multiple edges). A map \( \phi : V(G) \to V(H) \) is a homomorphism if every edge of \( G \) goes to an edge or loop of \( H \). In this paper, it is convenient to assume that \( H \) is a complete graph with a loop at all nodes by adding all missing edges and loops with weight 0. Then the weighted graph \( H \) is described by an integer \( q = |V(H)| \geq 0 \) (\( H \) can be the empty graph), a nowhere zero vector \( a = (\alpha_1, \ldots, \alpha_q) \in \mathbb{F}^q \) and a symmetric matrix \( \mathbf{B} = (\beta_{ij}) \in \mathbb{F}^{q \times q} \). In this setting every map \( \phi : V(G) \to V(H) \) is a homomorphism. We assign the weights

\[
\alpha_\phi = \prod_{u \in V(G)} \alpha_{H}(\phi(u)), \quad \text{hom}_{\phi}(G,H) = \prod_{uv \in E(G)} \beta_{H}(\phi(u),\phi(v)),
\]

(2.2)
and define
\[
\hom(G, H) = \sum_{\phi: V(G) \to V(H)} \alpha_{\phi} \hom_\phi(G, H).
\] (2.3)

When \( G \) is the empty graph, i.e., \( V(G) = \emptyset \), the only map \( \phi: \emptyset \to V(H) \) is the empty map \( \phi = \emptyset \); in that case we have the empty products \( \alpha_\emptyset = 1 \), \( \hom_\emptyset = 1 \), and \( \hom(G, H) = 1 \).

If all node-weights and edge-weights in \( H \) are 1, then this is the number of homomorphisms from \( G \) into \( H \). Without loss of generality we require all vertex weight \( \alpha_H(i) \neq 0 \) since any vertex \( i \) with \( \alpha_H(i) = 0 \) can be deleted together with all incident edges \( ij \) and loops at \( i \).

Note that when \( H \) is the empty graph, then \( \hom(G, H) = 0 \) if \( G \) is not the empty graph (because there is no map \( \phi: V(G) \to V(H) \) in this case), and \( \hom(G, H) = 1 \) if \( G \) is the empty graph (because there is precisely one empty map \( \phi = \emptyset \) in this case.) The function \( f_H = \hom(\cdot, H) \) is a graph parameter, a concept to be formally defined shortly.

3 Graph algebras

3.1 Basic definitions

An \( \mathbb{F} \)-valued graph parameter is a function from finite graph isomorphism classes to \( \mathbb{F} \). For convenience, we think of a graph parameter as a function defined on finite graphs and invariant under graph isomorphism. We allow multiple edges in our graphs, but no loops, as input to a graph parameter. A graph parameter \( f \) is called multiplicative, if for any disjoint union \( G_1 \sqcup G_2 \) of graphs \( G_1 \) and \( G_2 \) we have \( f(G_1 \sqcup G_2) = f(G_1)f(G_2) \).

A \( k \)-labeled graph \( (k \geq 0) \) is a finite graph in which \( k \) nodes are labeled by \( 1, 2, \ldots, k \) (the graph can have any number of unlabeled nodes). Two \( k \)-labeled graphs are isomorphic if there is a label-preserving isomorphism between them. We identify a \( (k \)-labeled) graph with its \( (k \)-labeled) graph isomorphism class. We denote by \( K_k \) the \( k \)-labeled complete graph on \( k \) nodes, and by \( U_k \), the \( k \)-labeled graph on \( k \) nodes with no edges. In particular, \( K_0 = U_0 \) is the empty graph with no nodes and no edges. A graph parameter on a labeled graph ignores its labels.

It is easy to see that for a multiplicative graph parameter \( f \), either \( f \) is identically 0 or \( f(K_0) = 1 \).

Every weighted graph homomorphism \( f_H = \hom(\cdot, H) \) is a multiplicative graph parameter.

The product of two \( k \)-labeled graphs \( G_1 \) and \( G_2 \) is defined as follows: we take their disjoint union, and then identify nodes with the same label. Hence for two 0-labeled graphs, \( G_1G_2 = G_1 \sqcup G_2 \) (disjoint union). Clearly, the graph product is associative and commutative with the identity \( U_k \), so the set of all isomorphism classes of finite \( k \)-labeled graphs together with the product operation forms a commutative monoid which we denote by \( \mathcal{PLG}[k] \).

Let \( \mathcal{G}[k] \) denote the monoid algebra \( \mathbb{F}\mathcal{PLG}[k] \) consisting of all finite formal linear combinations in \( \mathcal{PLG}[k] \) with coefficients from \( \mathbb{F} \); they are called \( (k \)-labeled, \( \mathbb{F} \)-)quantum graphs. This is a commutative algebra with \( U_k \) being the multiplicative identity, and the empty sum as the additive identity. Later, in Section 5 we will expand these definitions to allow label sets to be arbitrary finite subsets of \( \mathbb{Z}_{>0} \).

3.2 Connection tensors

Now we come to the central concept for our treatment. Let \( f \) be any graph parameter. For all integers \( k, n \geq 0 \), we define the following \( n \)-dimensional array \( T(f, k, n) \in \mathbb{F}^{(\mathcal{PLG}[k])^n} \), which
can be identified with \((V^\otimes n)^*\), where \(V\) is the infinite dimensional vector space with coordinates indexed by \(\mathcal{PLG}[k]\), i.e., \(V = \bigoplus_{\mathcal{PLG}[k]} \mathbb{F}\). The entry of \(T(f, k, n)\) at coordinate \((G_1, \ldots, G_n)\) is \(f(G_1 \cdots G_n)\); when \(n = 0\), we define \(T(f, k, n)\) to be the scalar \(f(U_k)\). Furthermore, by the commutativity of the product the arrays \(T(f, k, n)\) are symmetric with respect to its coordinates, i.e., \(T(f, k, n) \in \text{Sym}(\mathbb{F}[\mathcal{PLG}[k]^n])\). Fix \(f, k\) and \(n\), we call the \(n\)-dimensional array \(T(f, k, n)\) the \((k\text{-th, } n\text{-dimensional})\) connection tensor of the graph parameter \(f\). When \(n = 2\), a connection tensor is exactly a connection matrix of the graph parameter \(f\) studied in [19], i.e., \(T(f, k, 2) = M(f, k)\).

In contrast to [19], we will be concerned with only one property of connection tensors, namely their symmetric rank. Positive semidefiniteness that was central to the theory in [19] will not be required. The symmetric rank \(\text{rk}_S(f, k, n) = \text{rk}_S(T(f, k, n))\), as a function of \(k, n\), will be called the symmetric rank connectivity function of the parameter \(f\). This may be infinite, but for many interesting parameters it is finite, and its growth rate will be important for us.

**Remark:** In [19], the matrix rank of \(M(f, k)\) was used for the connection matrices. The results of this paper use the symmetric tensor rank of the connection tensors \(T(f, k, n)\) and hold for arbitrary fields. For \(n = 2\), tensor rank coincides with matrix rank, i.e., \(\text{rank}(T(f, k, 2)) = \text{rank}(M(f, k))\), and furthermore if \(\text{char} \mathbb{F} \neq 2\), then the symmetric tensor rank also coincides, \(\text{rk}_S(T(f, k, 2)) = \text{rank}(T(f, k, 2)) = \text{rank}(M(f, k))\). Since the field in [19] is \(\mathbb{R}\), the notions are consistent.

**Proposition 3.1.** Let \(f\) be a graph parameter that is not identically 0. The following are equivalent:

1. \(f\) is multiplicative.
2. \(f(K_0) = 1\) and for all \(n \geq 0\), \(\text{rk}_S(f, 0, n) = 1\).
3. \(f(K_0) = 1\) and there exists some \(n \geq 2\), \(\text{rk}_S(f, 0, n) = 1\).

**Proof.** Suppose \(f \neq 0\) is multiplicative. Then \(f(K_0)^2 = f(K_0)\), showing that \(f(K_0) \in \{0, 1\}\). If \(f(K_0) = 0\), then the relation \(f(G) = f(G)f(K_0)\) implies that \(f(G) = 0\) for every \(G\), which is excluded. So \(f(K_0) = 1\). Trivially \(\text{rk}_S(T(f, 0, n)) = 1\) for \(n = 0, 1\). Fix any \(n \geq 2\). Then \(f(G_1 \cdots G_n) = f(G_1) \cdots f(G_n)\) for any 0-labeled graphs \(G_1, \ldots, G_n\), which implies that \(\text{rk}_S(T(f, 0, n) = 1\).

Now suppose \(f(K_0) = 1\) and for some \(n \geq 2\), \(\text{rk}_S(f, 0, n) = 1\). This implies that there is a graph parameter \(\phi\) and a constant \(c_n\) such that \(f(G_1 \cdots G_n) = c_n \phi(G_1) \cdots \phi(G_n)\). Putting all \(G_i = K_0\), we get \(c_n \phi(K_0)^n = f(K_0) = 1\) so \(\phi(K_0) \neq 0\) and \(c_n = 1/\phi(K_0)^n\). Dividing \(\phi\) by \(\phi(K_0)\) we can assume that \(\phi\) is normalized so that \(f(G_1 \cdots G_n) = \phi(G_1) \cdots \phi(G_n)\) and \(\phi(K_0) = 1\). Next, taking \(G_1 = G\) and \(G_i = K_0\) for \(2 \leq i \leq n\) we see that \(f(G) = \phi(G)\) for every \(G\) and therefore \(f(G_1 \cdots G_n) = f(G_1) \cdots f(G_n)\). Finally, substituting \(G_1 = K_0\) for \(2 \leq i \leq n\), we get \(f(G_1G_2) = f(G_1)f(G_2)\) so \(f\) is multiplicative. \(\square\)

### 3.3 Connection tensors of homomorphisms

Fix a weighted graph \(H = (\alpha, B)\). Recall that in the definition of \(\text{hom}(\cdot, H)\) we assume \(H\) to be a complete graph with possible 0 weighted edges and loops, but no 0 weighted vertices. For any \(k\)-labeled graph \(G\) and mapping \(\phi: [k] \to V(H)\), let

\[
\text{hom}_\phi(G, H) = \sum_{\psi: V(G) \to V(H), \phi \text{ extends } \psi} \frac{\alpha_{\psi}}{\alpha_{\phi}} \text{hom}_\psi(G, H),
\]

where \(\alpha_{\phi} = \prod_{i \in [k]} \alpha(\phi(i))\), and \(\alpha_{\psi}\) and \(\text{hom}_\psi\) are defined by (3.2). Here \(\psi\) extends \(\phi\) means that if \(u_i \in V(G)\) is labeled by \(i \in [k]\) then \(\psi(u_i) = \phi(i)\), so \(\frac{\alpha_{\psi}}{\alpha_{\phi}}\) is the product of vertex weights of \(\alpha_{\psi}\) not
in $\alpha_\phi$. Then
\[
\text{hom}(G, H) = \sum_{\phi: [k] \to V(H)} \alpha_\phi \text{hom}_\phi(G, H). \tag{3.2}
\]

Our main contribution in this paper is that a simple exponential bound in $k$ on the symmetric rank of the connection tensor of a graph parameter characterizes it being expressible as $\text{hom} (\cdot, H)$. This holds over all fields $\mathbb{F}$. In contrast to the main theorem in \cite{19}, where the theory is restricted to weighted graphs $H = (\alpha, B)$ where $\alpha$ is positive and $B$ is real, the requirement of positive semi-definiteness is not needed here (and would not be meaningful for arbitrary fields).

**Theorem 3.2.** For any graph parameter defined by the graph homomorphism $f_H = \text{hom} (\cdot, H)$, we have $f_H(K_0) = 1$ and $\text{rk}_S (f_H, k, n) \leq |V(H)|^k$ for all $k, n \geq 0$.

**Proof.** The first claim is obvious, as an empty product is 1, and the sum in (2.3) is over the unique empty map $\emptyset$ which is the only possible map from the empty set $V(K_0)$. For the second claim notice that for any $k$-labeled graphs $G_1, \ldots, G_n$ and $\phi: [k] \to V(H)$,
\[
\text{hom}_\phi (G_1 \cdots G_n, H) = \text{hom}_\phi (G_1, H) \cdots \text{hom}_\phi (G_n, H). \tag{3.3}
\]
When $n = 0$, this equality is $\text{hom}_\phi (U_k, H) = 1$ according to (2.2), as an empty product is 1.

By (3.2) and (3.3), for the connection tensor $T(f_H, k, n)$ we have the following decomposition:
\[
T(f_H, k, n) = \sum_{\phi: [k] \to V(H)} \alpha_\phi \left( \text{hom}_\phi (\cdot, H) \right)^{\otimes n}
\]
where each $\text{hom}_\phi (\cdot, H) \in \mathbb{F}^{P \mathcal{L}^k}$ and $k, n \geq 0$. Now each $T(f_H, k, n)$ is a linear combination of $|V(H)|^k$ tensor $n$-powers and therefore $\text{rk}_S T(f_H, k, n) \leq q^k$ for $k, n \geq 0$. \qed

The main results of this paper are Theorems 3.3 and 3.4, a converse to Theorem 3.2.

**Theorem 3.3.** Let $f$ be a graph parameter for which $f(K_0) = 1$ and there exists a nonnegative integer $q$ such that $\text{rk}_S (f, k, n) \leq q^k$ for every $k, n \geq 0$. Then there exists a weighted graph $H$ with $|V(H)| \leq q$ such that $f = f_H$.

More generally,

**Theorem 3.4.** Let $f$ be a graph parameter for which $f(K_0) = 1$ and there exists a nonnegative integer $q$ such that for every $k \geq 0$ there exists $n \geq 2$ such that $\text{rk}_S (f, k, n) \leq \min(n - 1, q^k)$. Then there exists a weighted graph $H$ with $|V(H)| \leq q$ such that $f = f_H$.

Theorem 3.4 implies Theorem 3.3 by choosing a large $n$. Indeed if $\text{rk}_S (f, k, n) \leq q^k$, we may choose any $n \geq \max(q^k + 1, 2)$, which is $q^k + 1$ unless $q = 0$ and $k > 0$.

In Section 5 we will prove Theorem 3.4, then Theorem 3.3 also follows.

## 4 Applications

### 4.1 Tensor rank lower bound of certain tensors

We first state a lemma about the rank of the connection tensor for graph matchings. Let $M_{a,b} = M_{a:a,b} \in \text{Sym}^n (\mathbb{F}^2)$ denote the function $\{0, 1\}^n \to \mathbb{F}$ ($n \geq 0$), such that on the all-0 input $\mathbf{0}$ it takes
value $a$, on all inputs of Hamming weight one it takes value $b$, and on all other inputs it takes value 0. This function is denoted by $[a, b, 0, \ldots, 0]$ in the Holant literature. ($\mathcal{M}_{0; a, b}$ is just a constant $a$.) We have the following lemma; its proof is an adaptation of the proof of Lemma 5.1 in [15], and is given in subsection 6.1.

**Lemma 4.1.** If $b \neq 0$ and $n \geq 0$, then $\text{rk}_F \mathcal{M}_{n; a, b} \geq n$.

### 4.2 Perfect matchings

Let $\mathcal{F}$ be any set of $F$-valued constraint functions, a.k.a. signatures, from some finite set $[q]$. E.g., the binary \textsc{Equality} ($=2$) signature on $(x, y)$ outputs value 1 if $x = y$, and 0 otherwise. Similarly one can define \textsc{All-Distinct} on $[q]$, and \textsc{Exact-One} and \textsc{Exact-Two} on the Boolean domain ($q = 2$). An input to a Holant problem Holant$(\mathcal{F})$ is $\Omega = (G, \pi)$ where $G = (V, E)$ a graph (with possible multiple edges and loops), and $\pi$ assigns to each $v \in V$ some $f_v \in \mathcal{F}$ of arity $\deg(v)$, and its incident edges as inputs. The output is Holant$(G; \mathcal{F}) = \sum_{\sigma} \prod_{v \in V} f_v(\sigma | E(v))$, where the sum is over all edge assignments $\sigma : E \to [q]$, $E(v)$ denotes the incident edges of $v$ and $\sigma | E(v)$ denotes the restriction. Bipartite Holant$(G; \mathcal{F} | \mathcal{G})$ are defined on bipartite graphs $G = (U, V, E)$ where vertices in $U$ and $V$ are assigned signatures from $\mathcal{F}$ and $\mathcal{G}$ respectively.

The graph parameter that counts the number of perfect matchings in a graph, denoted by \#\textsc{Perfect-Matching} (or pm), is a quintessential Holant problem, corresponding to the \textsc{Exact-One} function. In this subsection we show it is not expressible as a GH function over any field. This was proved in [19] for real-valued GH with positive vertex weights. However that proof does not work for arbitrary fields, e.g., for the field of complex numbers $\mathbb{C}$, or even for real numbers with arbitrary (not necessarily positive) vertex weights. A crucial condition in [19] is positive semidefiniteness. Our main result (Theorems 3.2, 3.3 and 3.4) indicates that, to be expressible as GH, this condition of positive semidefiniteness is actually incidental if we state it for connection tensors; indeed the property of being a GH function is completely characterized by tensor rank.

Let $\text{pm}(G) = m \cdot 1 \in F$ (the sum of $m$ copies of $1 \in F$) where $m$ is the number of perfect matchings in $G$. Obviously, pm is a multiplicative graph parameter with $\text{pm}(K_0) = 1$. Next, let $G$ be a $k$-labeled graph, let $X \subseteq [k]$, and let $\text{pm}(G, X)$ denote the number of matchings in $G$ (expressed in $F$) that match all the unlabeled nodes and, for labeled nodes, exactly the nodes in $X$. Then for any $k$-labeled graphs $G_1, \ldots, G_n$,

$$\text{pm}(G_1 \cdots G_n) = \sum_{X_1 \sqcup \cdots \sqcup X_n = [k]} \text{pm}(G_1, X_1) \cdots \text{pm}(G_n, X_n).$$

This means that $T(\text{pm}, k, n)$ is the product $N^\otimes_k W_{k, n}$ where $N_k$ has infinitely many rows indexed by all $k$-labeled graphs $G$, but only $2^k$ columns indexed by the subsets $X$ of [k], with the entry at $(G, X)$

$$N_{k, G, X} = \text{pm}(G, X),$$

and $W_{k, n}$ is a symmetric $2^k \times \ldots \times 2^k$ tensor (from $\text{Sym}^n(\mathbb{F}^{2^k})$), where

$$W_{k, n; X_1, \ldots, X_n} = \begin{cases} 1 & \text{if } X_1 \sqcup \ldots \sqcup X_n = [k], \\ 0 & \text{otherwise.} \end{cases}$$
For any $k$, if $W_{k,n} = \sum_{i=1}^{r} a_i v_i^\otimes n$, then $T(pm, k, n) = \sum_{i=1}^{r} a_i (N_k v_i)^\otimes n$. Hence $rk_S T(pm, k, n) \leq rk_S W_{k,n}$. We show that in fact equality holds. Consider the family of $k$-labeled graphs $\{P_X\}_{X \subseteq [k]}$ of cardinality $2^k$ indexed by the subsets of $[k]$ and defined as follows: each $P_X$ has $|X|$ unlabeled vertices $\{x_i\}_{i \in X}$ and $k$ labeled vertices $\{y_i\}_{i=1}^{n}$ labeled 1 to $k$, with an edge between $x_i$ and $y_j$ iff $i = j$. It is easy to see that for $X, Y \subseteq [k]$, $N_k P_X Y = 1$ if $X = Y$ and 0 otherwise. Then if we consider the subset of rows in $N_k$ corresponding to $\{P_X\}_{X \subseteq [k]}$ we see that they form the identity matrix $I_{2^k}$ with a suitable order of rows. Therefore $rk_S W_{k,n} = rk_S (I_{2^k} \otimes n W_{k,n}) \leq rk_S T(pm, k, n)$ and so $rk_S T(pm, k, n) = rk_S W_{k,n}$.

Note that for $k = 1$, $W_{1,n}$ is just the perfect matching tensor (or the Exact-One function on $n$ inputs) $M_{0,1} \in \text{Sym}^n(\mathbb{F}^2)$ where $n \geq 1$. Applying Lemma 4.1 with $a = 0, b = 1$, we get $rk_S W_{1,n} \geq n$ and therefore $rk_S T(pm, 1, n) \geq n$ for $n \geq 1$. Now if $pm$ were expressible as $\text{hom}(\cdot, H)$ for some weighted graph $H$ with $q = |V(H)|$, then by Theorem 3.2, $rk_S T(pm, k, n) \leq q^k$ for $k, n \geq 0$ so that $rk_S T(pm, 1, n) \leq q$ for $n \geq 0$. However, as we have just shown $rk_S T(pm, 1, n) \geq n$ for $n \geq 1$ which contradicts the upper bound when $n > q$. Hence $pm$ is not expressible as a graph homomorphism function over any field. We state it as a theorem:

**Theorem 4.2.** The graph parameter $\#\text{Perfect-Matching} (pm)$ is not expressible as a graph homomorphism function over any field.

In this proof we have only used simple $k$-labeled graphs that do not have edges between the $k$ labeled vertices. The graphs $\{P_X\}_{X \subseteq [k]}$ clearly have this property, and this property is preserved under product of $k$-labeled graphs. It follows that Theorem 4.2 holds even when $pm$ is restricted to simple graphs.

We can prove the same inexpressibility results for weighted matchings, proper edge colorings, and vertex disjoint cycle covers (see Section 6). For bounded degree graphs we can also prove

**Theorem 4.3.** Let $\mathbb{F}$ be a field and $d \geq 2$. Then for the graph parameter $\#\text{Perfect-Matching} (pm)$ as a function defined on degree-$d$ bounded graphs the following hold:
1. $pm$ is not expressible as $\text{hom}(\cdot, H)$ with $|V(H)| < d$ even on degree-$d$ bounded simple graphs.
2. If $\mathbb{F}$ is infinite, then $pm$ is expressible as $\text{hom}(\cdot, H)$ with $|V(H)| = d$ unless $\text{char} \mathbb{F} = 2$ and $d = 2$ (and in which case the minimum value is $|V(H)| = d + 1 = 3$.)

5 Proof of Main Theorem

For now, we do not make any assumptions on the graph parameter $f$; we will introduce more assumptions as needed to prove the desired statements. When we speak of submonoids, subrings and subalgebras we require that the multiplicative identity coincide with that of the larger structure. When a subset with the induced operations forms a monoid, ring or algebra we will simply say that it is respectively a monoid, ring or algebra in the larger structure. We allow zero algebras and rings, in which $0 = 1$. Statements about such structures can be easily checked. A function of arity zero is a scalar. We identify a (labeled) graph with its (labeled) graph isomorphism class.

5.1 The monoid and algebra of graphs

For every finite set $S \subseteq \mathbb{Z}_{>0}$, we denote by $U_S$ the graph with $|S|$ nodes labeled by $S$ and no edges. Note that $U_0 = K_0$ is the empty graph.
We put all $k$-labeled graphs into a single structure as follows. By a partially labeled graph we mean a finite graph in which some of the nodes are labeled by distinct positive integers. (All label sets are finite.) Two partially labeled graphs are isomorphic if there is an isomorphism between them preserving all labels. For two partially labeled graphs $G_1$ and $G_2$, let $G_1G_2$ denote the partially labeled graph obtained by taking the disjoint union of $G_1$ and $G_2$, and identifying the nodes with the same label; the union of the label sets becomes the labels of $G_1G_2$. This way we obtain a commutative monoid $\mathcal{PLG}$ consisting of all isomorphism classes of finite partially labeled graphs with the empty graph $U_0$ being the identity \footnote{In \cite{19}, the word semigroup instead of monoid is used. A monoid is a semigroup with identity, and all semigroups in \cite{19} have or assume to have identity. Thus, our use of the term monoid is consistent with that of \cite{19}. }. For every finite set $S \subseteq \mathbb{Z}_{>0}$, we call a partially labeled graph $S$-labeled, if its labels form the set $S$. We call a partially labeled graph $\subseteq S$-labeled, if its labels form a subset of $S$. We define $\mathcal{PLG}(S)$, respectively $\mathcal{PLG}_{\subseteq}(S)$, to be the subset of $\mathcal{PLG}$ consisting of all isomorphism classes of $S$-labeled, respectively $\subseteq S$-labeled, graphs. Clearly $\mathcal{PLG}(S) \subseteq \mathcal{PLG}_{\subseteq}(S)$. Then both $\mathcal{PLG}(S)$ and $\mathcal{PLG}_{\subseteq}(S)$ are commutative monoids in $\mathcal{PLG}$. $\mathcal{PLG}_{\subseteq}(S)$ is a submonoid of $\mathcal{PLG}$ with the same identity $U_0$, while $\mathcal{PLG}(S)$ is a submonoid of $\mathcal{PLG}$ iff $S = \emptyset$, as the identity in $\mathcal{PLG}(S)$ is $U_S$.

Let $\mathcal{G}$ denote the monoid algebra $\mathbb{F}\mathcal{PLG}$ consisting of all finite formal linear combinations in $\mathcal{PLG}$ with coefficients from $\mathbb{F}$; they are called (partially labeled, $\mathbb{F}$-)quantum graphs. Restricting the labels to precisely $S$ or to subsets of $S$, we have $\mathbb{F}\mathcal{PLG}(S)$ or $\mathbb{F}\mathcal{PLG}_{\subseteq}(S)$, respectively the $S$-labeled or $\subseteq S$-labeled quantum graphs, respectively denoted by $\mathcal{G}(S)$ or $\mathcal{G}_{\subseteq}(S)$. $\mathcal{G}(S)$ is an algebra inside $\mathcal{G}$ with $U_S$ being the multiplicative identity, and $\mathcal{G}_{\subseteq}(S)$ is a subalgebra of $\mathcal{G}$. The empty sum is the additive identity in all.

Because many definitions, notations and statements for $\mathcal{PLG}(S), \mathcal{G}(S)$ and $\mathcal{PLG}_{\subseteq}(S), \mathcal{G}_{\subseteq}(S)$ appear similar, we will often concommingle them to minimize repetitions, e.g., we use $\mathcal{G}_{\subseteq}(S)$ to denote either $\mathcal{G}(S)$ or $\mathcal{G}_{\subseteq}(S)$ (and the statements are asserted for both).

We can extend $f$ to a linear map on $\mathcal{G}$, and define an $n$-fold multilinear form, where $n \geq 1$, $$(x_1, \ldots, x_n)(n) = f(x_1 \cdots x_n), \quad \text{for } x_1, \ldots, x_n \in \mathcal{G}.$$ It is symmetric because $\mathcal{G}$ is commutative. Note that if we restrict each argument to $\mathcal{G}[k]$ and then write it with respect to the basis $\mathcal{PLG}[k]$ of $\mathcal{G}[k]$, we get precisely the connection tensor (array) $T(f, k, n)$.

Let $$\mathcal{K} = \{ x \in \mathcal{G} : f(xy) = \langle x, y \rangle = 0 \forall y \in \mathcal{G} \}$$ be the annihilator of $\mathcal{G}$. Clearly, $\mathcal{K}$ is an ideal in $\mathcal{G}$, so we can form the quotient algebra $\hat{\mathcal{G}} = \mathcal{G}/\mathcal{K}$ which is commutative as well. We denote its identity by $u_\emptyset = U_0 + \mathcal{K}$. More generally, we denote $u_S = U_S + \mathcal{K}$ for any finite subset $S \subseteq \mathbb{Z}_{>0}$. If $x \in \mathcal{K}$, then $f(x) = f(xU_0) = 0$ and so $f$ can also be considered as a linear map on $\hat{\mathcal{G}}$ by $f(x + \mathcal{K}) = f(x) + \mathcal{K}$ for $x \in \mathcal{G}$. For a partially labeled graph $G$ we denote by $\hat{G} = G + \mathcal{K}$ the corresponding element of $\hat{\mathcal{G}}$. More generally, we write $\hat{x} = x + \mathcal{K}$ for any $x \in \mathcal{G}$. Since $\mathcal{K}$ is an ideal in $\mathcal{G}$, the form $\langle \cdot, \ldots, \cdot \rangle(n)$ on $\mathcal{G}$ induces an $n$-fold multilinear symmetric form on $\hat{\mathcal{G}}$, where $n \geq 1$,

$$\langle x_1, \ldots, x_n \rangle(n) = f(x_1 \cdots x_n), \quad \text{for } x_1, \ldots, x_n \in \hat{\mathcal{G}}. \quad (5.1)$$

We can also define

$$\hat{\mathcal{G}}_{\subseteq}(S) = (\mathcal{G}_{\subseteq}(S) + \mathcal{K})/\mathcal{K} = \{ x + \mathcal{K} \mid x \in \mathcal{G}_{\subseteq}(S) + \mathcal{K} \} = \{ x + \mathcal{K} \mid x \in \mathcal{G}_{\subseteq}(S) \}.$$
It is easy to see that \( \hat{G}_C(S) \) is a subalgebra of \( \hat{G} \) with the same identity \( u_0 = U_0 + K \), and \( \hat{G}(S) \) is an algebra inside \( \hat{G} \) with the identity \( u_S = U_S + K \) \(^4\).

If \( S, T \subseteq \mathbb{Z}_{>0} \) are finite subsets, then \( \mathcal{PLG}_C(S) \mathcal{PLG}_C(T) \subseteq \mathcal{PLG}_C(S \cup T) \) so by linearity we get \( \hat{G}_C(S) \hat{G}_C(T) \subseteq \hat{G}_C(S \cup T) \) and so, going to the quotients, we have \( \hat{G}_C(S) \hat{G}_C(T) \subseteq \hat{G}_C(S \cup T) \). Also note that for a finite \( S \subseteq \mathbb{Z}_{>0} \), we have \( \mathcal{PLG}(S) \subseteq \mathcal{PLG}_C(S) \) so by linearity \( \hat{G}(S) \subseteq \hat{G}_C(S) \) and then by going to the quotients we obtain \( \hat{G}(S) \subseteq \hat{G}_C(S) \).

Since \( \hat{G}_C(S) \cap K \) is an ideal in \( \hat{G}_C(S) \), we can also form another quotient algebra
\[
\hat{G}_C(S) = \hat{G}_C(S)/(\hat{G}_C(S) \cap K).
\]

We have the following canonical isomorphisms between \( \hat{G}_C(S) \) and \( \hat{G}_C(S) \).

**Lemma 5.1.** Let \( S \subseteq \mathbb{Z}_{>0} \) be finite. Then \( \hat{G}_C(S) \cong \hat{G}_C(S) \) as algebras via \( x + \hat{G}_C(S) \cap K \mapsto x + K, x \in \hat{G}_C(S) \).

**Proof.** It follows from the Second Isomorphism Theorem for algebraic structures (see [14] p. 8). \( \square \)

We say that elements \( x, y \in \hat{G} \) (or \( \hat{G} \)) are orthogonal (with respect to \( f \)), if \( f(xy) = 0 \) and denote it by \( x \perp y \). For a subset \( A \subseteq \hat{G} \) (or \( \hat{G} \)), denote by \( A^\perp = \{ x \in \hat{G} \mid x \perp y, \forall y \in A \} \) those in \( \hat{G} \) (or \( \hat{G} \)) orthogonal to all elements in \( A \). Next, we say that subsets \( A, B \subseteq \hat{G} \) (or \( \hat{G} \)) are orthogonal (with respect to \( f \)), if \( x \perp y \) for all \( x \in A \) and \( y \in B \). Similarly, we can talk about an element of \( \hat{G} \) (or \( \hat{G} \)) being orthogonal to a subset of \( \hat{G} \) (or \( \hat{G} \)) and vice versa. Note that the notion of orthogonality is symmetric since all the multiplication operations considered are commutative.

From the definition, we have \( K = \hat{G}^\perp \). Next, denote (commingling the notations \( K_S \) and \( K_{C_S} \))
\[
K_{C,S} = \{ x \in \hat{G}_{C,S} \mid x \perp y, \forall y \in \hat{G}_{C,S} \} = \hat{G}_{C,S} \cap (\hat{G}_{C,S})^\perp.
\]

Clearly, \( K_{C,S} \) is an ideal in \( \hat{G}_{C,S} \), so we can form yet another quotient algebra \( \hat{G}_{C,S}/K_{C,S} \).

Next, we define an orthogonal projection from \( \hat{G} \) to the subalgebra \( \hat{G}_C(S) \). We will show how to do it in a series of lemmas. Let \( S \subseteq \mathbb{Z}_{>0} \) be finite. For every partial labeled graph \( G \), let \( G_S \) denote the \( \subseteq S \)-labeled graph obtained by deleting the labels not in \( S \) from the vertices of \( G \) (unlabeling such vertices). Extending this map by linearity, we get a linear map \( \pi_S : \hat{G} \to \hat{G}_C(S) \). Note that \( (\pi_S)_{|\hat{G}_C(S)} = \text{id}_{\hat{G}_C(S)} \). In particular, \( \pi_S : \hat{G} \to \hat{G}_C(S) \) is surjective.

**Lemma 5.2.** Let \( S \subseteq \mathbb{Z}_{>0} \) be finite. If \( x \in \hat{G} \) and \( y \in \hat{G}_C(S) \), then
\[
f(xy) = f(\pi_S(x)y).
\]

**Proof.** For every \( G_1 \in \mathcal{PLG} \) and \( G_2 \in \mathcal{PLG}_C(S) \), the graphs \( G_1G_2 \) and \( \pi_S(G_1)G_2 \) are isomorphic as unlabeled graphs. Hence \( f(G_1G_2) = f(\pi_S(G_1)G_2) \) as \( f \) ignores labels. The lemma follows by linearity. \( \square \)

**Corollary 5.3.** Let \( S \subseteq \mathbb{Z}_{>0} \) be finite. If \( x \in \hat{G} \), then \( x - \pi_S(x) \in (\hat{G}_C(S))^\perp \).

**Proof.** Fix any \( y \in \hat{G}_C(S) \). By Lemma 5.2, \( f(xy) = f(\pi_S(x)y) \) so \( f((x - \pi_S(x))y) = 0 \). Thus \( x - \pi_S(x) \in (\hat{G}_C(S))^\perp \). \( \square \)

\(^4\)In contrast to [19] we cannot normalize \( f \) to make all elements \( u_S \), for finite \( S \subseteq \mathbb{Z}_{>0} \), the same in the quotient algebra \( \hat{G} \). In our more general setting, it is possible \( f(K_1) = 0 \), in which case the normalization step from [19] fails.
So for any $x \in \mathcal{G}$, we can write $x = \pi_S(x) + (x - \pi_S(x))$ where $\pi_S(x) \in \mathcal{G}_\subseteq(S)$, and $x - \pi_S(x) \in (\mathcal{G}_\subseteq(S))^\perp$. This gives a decomposition $\mathcal{G} = \mathcal{G}_\subseteq(S) + (\mathcal{G}_\subseteq(S))^\perp$. To get a direct sum decomposition, we need to pass to the quotient algebra. But to do so properly we need some lemmas.

**Lemma 5.4.** Let $S \subseteq \mathbb{Z}_{>0}$ be finite. Then $\mathcal{K}_S = \mathcal{G}(S) \cap \mathcal{K}$.

**Proof.** Clearly, $\mathcal{G}(S) \cap \mathcal{K} = \mathcal{G}(S) \cap \mathcal{G}^\perp \subseteq \mathcal{G}(S) \cap (\mathcal{G}(S))^\perp = \mathcal{K}_S$, so we only need to prove the reverse inclusion. Let $x \in \mathcal{K}_S \subseteq \mathcal{G}(S) \cap (\mathcal{G}(S))^\perp$. Take any $y \in \mathcal{G}$. Then

$$f(xy) \overset{(1)}{=} f(x\pi_S(y)) \overset{(2)}{=} f(xU_S\pi_S(y)) \overset{(3)}{=} 0.$$  

Here step (1) uses Lemma 5.2 as $x \in \mathcal{G}(S) \subseteq \mathcal{G}_\subseteq(S)$; (2) is true because $x = xU_S$ for $x \in \mathcal{G}(S)$; (3) is true as $\pi_S(y) \in \mathcal{G}_\subseteq(S)$ so $U_S\pi_S(y) \in \mathcal{G}(S)$, and as $x \in (\mathcal{G}(S))^\perp$. Then $x \in \mathcal{K}$ so $x \in \mathcal{G}(S) \cap \mathcal{K}$, implying $\mathcal{K}_S \subseteq \mathcal{G}(S) \cap \mathcal{K}$. \hfill \Box

**Lemma 5.5.** Let $S \subseteq \mathbb{Z}_{>0}$ be finite. Then $\mathcal{K}_S = \mathcal{G}_\subseteq(S) \cap \mathcal{K}$.

**Proof.** Clearly, $\mathcal{G}_\subseteq(S) \cap \mathcal{K} = \mathcal{G}_\subseteq(S) \cap \mathcal{G}^\perp \subseteq \mathcal{G}_\subseteq(S) \cap (\mathcal{G}_\subseteq(S))^\perp = \mathcal{K}_S$, so we only need to prove the reverse inclusion. Let $x \in \mathcal{K}_S = \mathcal{G}_\subseteq(S) \cap (\mathcal{G}_\subseteq(S))^\perp$. Take any $y \in \mathcal{G}$. Then

$$f(xy) \overset{(1)}{=} f(x\pi_S(y)) \overset{(2)}{=} 0.$$  

Here step (1) uses Lemma 5.2; (2) is true as $\pi_S(y) \in \mathcal{G}_\subseteq(S)$ and $x \in (\mathcal{G}_\subseteq(S))^\perp$. Then $x \in \mathcal{K}$ so $x \in \mathcal{G}_\subseteq(S) \cap \mathcal{K}$, implying $\mathcal{K}_S \subseteq \mathcal{G}_\subseteq(S) \cap \mathcal{K}$. \hfill \Box

It follows from Lemmas 5.4 and 5.5 that $\mathcal{G}_\subseteq(S)/\mathcal{K}_S = \mathcal{G}_\subseteq(S)/(\mathcal{G}_\subseteq(S) \cap \mathcal{K}) = \hat{\mathcal{G}}_{\subseteq}(S)$ so the (canonical) isomorphism of algebras from Lemma 5.1 takes the following form:

$$\hat{\mathcal{G}}_{\subseteq}(S) \cong \hat{\mathcal{G}}_{\subseteq}(S), \quad x + \mathcal{K}_S \mapsto x + \mathcal{K}, \quad x \in \mathcal{G}_\subseteq(S).$$

(5.2)

**Lemma 5.6.** Let $S \subseteq \mathbb{Z}_{>0}$ be finite. For the linear map $\pi_S \colon \mathcal{G} \to \mathcal{G}_\subseteq(S)$ we have $\pi_S(\mathcal{K}) = \mathcal{K}_S$.

**Proof.** Because $(\pi_S)_{\mathcal{G}_\subseteq(S)} = \text{id}_{\mathcal{G}_\subseteq(S)}$ and by Lemma 5.5 $\mathcal{K}_S = \mathcal{G}_\subseteq(S) \cap \mathcal{K}$, we infer that $\pi_S(\mathcal{K}) \supseteq \mathcal{K}_S$. For the reverse inclusion, let $x \in \mathcal{K}$. Fix any $y \in \mathcal{G}_\subseteq(S)$. Then by Lemma 5.2, $f(\pi_S(x)y) = f(xy) = 0$, the last equality is true because $x \in \mathcal{K}$. Hence $\pi_S(x) \in \mathcal{K}_S$ so that $\pi_S(\mathcal{K}) \subseteq \mathcal{K}_S$. \hfill \Box

For the linear map $\pi_S \colon \mathcal{G} \to \mathcal{G}_\subseteq(S) \subseteq \mathcal{G}$ by Lemmas 5.6 and 5.5, $\pi_S(\mathcal{K}) = \mathcal{K}_S = \mathcal{G}_\subseteq(S) \cap \mathcal{K}$, so that we have the well-defined linear map (which we denote by $\hat{\pi}_S$)

$$\hat{\pi}_S : \hat{\mathcal{G}} \to \hat{\mathcal{G}}_{\subseteq}, \quad \hat{\pi}_S(x + \mathcal{K}) = \pi_S(x) + \mathcal{K}, \quad x \in \mathcal{G}.$$  

(5.3)

It is easy to see that $(\hat{\pi}_S)_{\hat{\mathcal{G}}_\subseteq(S)} = \text{id}_{\hat{\mathcal{G}}_\subseteq(S)}$. In particular, $\hat{\pi}_S : \hat{\mathcal{G}} \to \hat{\mathcal{G}}_{\subseteq(S)}$ is surjective.

**Lemma 5.7.** Let $S \subseteq \mathbb{Z}_{>0}$ be finite. Then $\hat{\mathcal{G}} = \hat{\mathcal{G}}_\subseteq(S) \oplus (\hat{\mathcal{G}}_\subseteq(S))^\perp$ via $x = \hat{\pi}_S(x) + (x - \hat{\pi}_S(x))$, $x \in \hat{\mathcal{G}}$.

**Proof.** First, let $x \in \hat{\mathcal{G}}$. Write $x = y + \mathcal{K}$ where $y \in \mathcal{G}$. Then $\hat{\pi}_S(x) = \pi_S(y) + \mathcal{K}$ and $\pi_S(y) \in \mathcal{G}_\subseteq(S)$. We have $x - \hat{\pi}_S(x) = y - \pi_S(y) + \mathcal{K}$. By Corollary 5.3, $y - \pi_S(y) \in (\mathcal{G}_\subseteq(S))^\perp$ so that $x - \hat{\pi}_S(x) \in (\hat{\mathcal{G}}_\subseteq(S))^\perp$, since the bilinear form on $\mathcal{G}$ extends to $\hat{\mathcal{G}}$ in (5.1).

So we only need to show that $\hat{\mathcal{G}}_\subseteq(S) \cap (\hat{\mathcal{G}}_\subseteq(S))^\perp = 0 = \{0\}$. Let $z$ belong to this intersection. Write $z = t + \mathcal{K} = t' + \mathcal{K}$ where $t \in \mathcal{G}_\subseteq(S)$ and $t' \in (\mathcal{G}_\subseteq(S))^\perp$. Then clearly $t - t' \in \mathcal{K} \subseteq (\mathcal{G}_\subseteq(S))^\perp$, and so $t = (t - t') + t' \in (\mathcal{G}_\subseteq(S))^\perp$. Thus $t \in \mathcal{G}_\subseteq(S) \cap (\mathcal{G}_\subseteq(S))^\perp = \mathcal{K}_S \subseteq \mathcal{K}$, the last inclusion holds by Lemma 5.5. Therefore $z = t + \mathcal{K} = \mathcal{K}$, implying that $\hat{\mathcal{G}}_\subseteq(S) \cap (\hat{\mathcal{G}}_\subseteq(S))^\perp = 0$. \hfill \Box
Thus Lemma 5.7 allows us to rightfully call \( \hat{\pi}_S : \hat{G} \to \hat{G}_S(\subseteq) \) an orthogonal projection of \( \hat{G} \) to \( \hat{G}_S(\subseteq) \).

If \( S, T \subseteq \mathbb{Z}_{>0} \) are finite subsets, then \( \pi_S(\mathcal{P}L\mathcal{G}(\subseteq)(T)) = \mathcal{P}L\mathcal{G}_S(\subseteq)(S \cap T) \), where the projection is surjective because the restriction \((\pi_S)_{\mathcal{P}L\mathcal{G}(\subseteq)(S \cap T)} = \text{id}_{\mathcal{P}L\mathcal{G}_S(\subseteq)(S \cap T)}\). So by linearity we get
\[
\pi_S(\mathcal{G}(\subseteq)(T)) = \mathcal{G}_S(\subseteq)(S \cap T).
\]
Going to the quotients, we conclude that \( \hat{\pi}_S(\hat{G}(\subseteq)(T)) = \hat{G}_S(\subseteq)(S \cap T) \).

**Lemma 5.8.** Let \( n \geq 2 \) and \( S \subseteq \mathbb{Z}_{>0} \) be finite. Then for any \( x \in \mathcal{G}(\subseteq)(S) \), we have \( x \in \mathcal{K}(\subseteq)S \) iff \( f(x_1 \cdots x_{n-1}) = 0 \) for all \( x_1, \ldots, x_{n-1} \in \mathcal{G}(\subseteq)(S) \).

**Proof.** For \( \Rightarrow \), it suffices to note that \( \mathcal{G}(\subseteq)(S) \) is closed under multiplication (in \( \mathcal{G} \)). To prove \( \Leftarrow \), note that \( n - 2 \geq 0 \) and for any \( y \in \mathcal{G}(\subseteq)(S) \), we have \( f(xy) = f(xyU^{n-2}) = 0 \), where \( U = U_0 \) in the \( \mathcal{G}(\subseteq)(S) \) case and \( U = U_S \) in the \( \mathcal{G}(S) \) case, so \( x \in \mathcal{K}(\subseteq)S \).

**Lemma 5.9.** Let \( S \subseteq \mathbb{Z}_{>0} \) be finite. Then the annihilator of \( \hat{G}(\subseteq)(S) \) in \( \hat{G}_S(\subseteq) \) is zero, i.e., if \( x \in \hat{G}_S(\subseteq) \) and \( f(xy) = 0 \) for every \( y \in \hat{G}_S(\subseteq) \), then \( x \) is the zero element of \( \hat{G}(\subseteq)(S) \), namely \( \mathcal{K} \).

**Proof.** Let \( x \in \hat{G}_S(\subseteq) \) be an element satisfying the hypothesis of the lemma. Write \( x = h_1 + \mathcal{K} \) where \( h_1 \in \mathcal{G}(\subseteq)(S) \). By hypothesis, for every \( y \in \hat{G}_S(\subseteq) \) we have \( f(xy) = 0 \). Let \( h_2 \in \mathcal{G}(\subseteq)(S) \) and put \( y = h_2 + \mathcal{K} \in \hat{G}_S(\subseteq) \). Then \( xy = h_1h_2 + \mathcal{K} \). By the definition of \( f \) on \( \hat{G} \), \( f(h_1h_2) = f(xy) = 0 \). Hence \( h_1 \in \mathcal{K}S \subseteq \mathcal{K} \) where the last inclusion is true by Lemmas 5.4 and 5.5. This implies that \( x \) is the zero element of \( \hat{G}(\subseteq)(S) \), which is \( \mathcal{K} \).

**Lemma 5.10.** Let \( k, r \geq 0 \) and \( n \geq \max(2, r) \). Suppose the connection tensor \( T(f, k, n) \) can be expressed as
\[
T(f, k, n) = \sum_{i=1}^{r} a_i \mathcal{X}_i^{\otimes n},
\]
where \( a_i \neq 0 \) and \( \mathcal{X}_i \in \mathbb{F}^{\mathcal{P}L\mathcal{G}[k]} \) are nonzero and pairwise linearly independent for \( 1 \leq i \leq r \). Then for any \( h \in \mathcal{G}[k] \), we have \( h \in \mathcal{K}[k] \) iff \( \mathcal{X}_i(h) = 0 \), \( 1 \leq i \leq r \).

**Proof.** The lemma is clearly true for \( r = 0 \). Let \( r \geq 1 \). By Lemma 5.8, \( h \in \mathcal{K}[k] \) iff \( f(h_1 \cdots h_{n-1}) = 0 \) for all \( h_1, \ldots, h_{n-1} \in \mathcal{G}[k] \). In terms of \( T(f, k, n) \), this is equivalent to \( (T(f, k, n))(h, \cdot, \ldots, \cdot) = 0 \) which is the same as
\[
\sum_{i=1}^{r} a_i \mathcal{X}_i(h) \mathcal{X}_i^{\otimes (n-1)} = 0.
\]
Now if \( \mathcal{X}_i(h) = 0 \), \( 1 \leq i \leq r \), then this equality clearly holds. Conversely, if this equality holds, then by Lemma 2.5, \( a_i \mathcal{X}_i(h) = 0 \) but \( a_i \neq 0 \) so \( \mathcal{X}_i(h) = 0 \), \( 1 \leq i \leq r \).

We will also need the following lemma that classifies all subalgebras of \( \mathbb{F}^m \) for \( m \geq 0 \). A proof is given in subsection 8.3 of the Appendix. Recall that we allow zero algebras and require any subalgebra of an algebra to share the multiplicative identity.

**Lemma 5.11.** All subalgebras of \( \mathbb{F}^m \), where \( m \geq 0 \), are of the following form: For some partition [\( m \)] = \( \bigsqcup_{i=1}^{s} I_s \), where \( s \geq 0 \), and \( I_i \neq \emptyset \) for \( i \in [s] \), the subalgebra has equal values on each \( I_i \),
\[
\mathbb{F}(I_1, \ldots, I_s) = \{(c_1, \ldots, c_m) \in \mathbb{F}^m \mid \forall i \in [s], \forall j, j' \in I_i, c_j = c_{j'} \}. 
\]

14
5.2 Building an algebra isomorphism

In this part of the proof regarding $f$, for an arbitrary fixed $k \geq 0$, we assume that there exists $n = n_k \geq 2$ such that $r_k \leq n - 1$. We will pick an arbitrary such $n$ and call it $n_k$, and then write $r_k = r_k S(f, k, n_k)$. (Note that this is weaker than the uniform exponential boundedness in $k$ for $r_k S(f, k, n)$ in Theorem 3.3, nor do we require $f(K_0) = 1$ here.)

Then, for $n = n_k$, we can write,

$$T(f, k, n) = \sum_{i=1}^{r_k} a_{k, n, i} x_{k, n, i}^\otimes n.$$  \hspace{1cm} (5.4)

Then $a_{k, n, i} \neq 0$ and $0 \neq x_{k, n, i} \in \mathbb{P}^C G[k]$ are pairwise linearly independent for $1 \leq i \leq r_k$.

Define the linear map

$$\Phi_{k, n} : G[k] \rightarrow \mathbb{R}^{r_k}, \quad \Phi_{k, n} (h) = (x_{k, n, i}(h))_{i=1, \ldots, r_k}, \quad h \in G[k].$$  \hspace{1cm} (5.5)

We show that $\Phi_{k, n} : G[k] \rightarrow \mathbb{R}^{r_k}$ is a surjective algebra homomorphism. Clearly, as $n \geq 2$,

$$h_1 \cdot h_2 \cdot h_3 \cdots h_n = (h_1 h_2) \cdot U_k \cdot h_3 \cdots h_n$$

so

$$f(h_1 \cdot h_2 \cdot h_3 \cdots h_n) = f((h_1 h_2) \cdot U_k \cdot h_3 \cdots h_n)$$

for all $h_1, \ldots, h_n \in G[k]$. (When $n = 2$ this is $f(h_1 h_2) = f((h_1 h_2) U_k)$.) Therefore

$$(T(f, k, n))(h_1, h_2, \ldots, \cdot) = (T(f, k, n))(h_1 h_2, U_k, \cdot, \ldots, \cdot)$$

for all $h_1, h_2 \in G[k]$. In terms of the decomposition in (5.4), this is equivalent to

$$\sum_{i=1}^{r_k} a_{k, n, i} x_{k, n, i}(h_1) x_{k, n, i}(h_2) x_{k, n, i}^\otimes (n-2) = \sum_{i=1}^{r_k} a_{k, n, i} x_{k, n, i}(h_1 h_2) x_{k, n, i}(U_k) x_{k, n, i}^\otimes (n-2).$$

It follows that

$$\sum_{i=1}^{r_k} a_{k, n, i} (x_{k, n, i}(h_1) x_{k, n, i}(h_2) - x_{k, n, i}(h_1 h_2) x_{k, n, i}(U_k)) x_{k, n, i}^\otimes (n-2) = 0$$

for any $h_1, h_2 \in G[k]$. The condition $r_k \leq n - 1$ allows us to apply Lemma 2.5. Since $a_{k, n, i} \neq 0$ for $1 \leq i \leq r_k$, we obtain that

$$x_{k, n, i}(h_1) x_{k, n, i}(h_2) = x_{k, n, i}(h_1 h_2) x_{k, n, i}(U_k), \quad h_1, h_2 \in G[k], \quad 1 \leq i \leq r_k.$$  \hspace{1cm} (5.6)

Let $1 \leq i \leq r_k$. Since $x_{k, n, i} \neq 0$, there exists $h \in G[k]$ such that $x_{k, n, i}(h) \neq 0$. Substituting $h_1 = h_2 = h$ into (5.6), we infer that $x_{k, n, i}(U_k) \neq 0, 1 \leq i \leq r_k$.

Therefore we can assume in (5.4) that each $x_{k, n, i}$ is normalized so that $x_{k, n, i}(U_k) = 1$ ($1 \leq i \leq r_k$). Combined with this, condition (5.6) becomes for $1 \leq i \leq r_k$,

$$\begin{cases}
    x_{k, n, i}(h_1 h_2) = x_{k, n, i}(h_1) x_{k, n, i}(h_2), & h_1, h_2 \in G[k]; \\
    x_{k, n, i}(U_k) = 1;
\end{cases}$$  \hspace{1cm} (5.7)
so the linear functions \( x_{k,n,i} : G[k] \to F \), \( 1 \leq i \leq r_k \) are algebra homomorphisms. Then we have

\[
\Phi_{k,n}(gh) = (x_{k,n,1}(gh), \ldots, x_{k,n,r_k}(gh)) = (x_{k,n,1}(g)x_{k,n,1}(h), \ldots, x_{k,n,r_k}(g)x_{k,n,r_k}(h))
= (x_{k,n,1}(g), \ldots, x_{k,n,r_k}(g)) \cdot (x_{k,n,1}(h), \ldots, x_{k,n,r_k}(h)) = \Phi_{k,n}(g)\Phi_{k,n}(h).
\]

So we have

\[
\Phi_{k,n}(gh) = \Phi_{k,n}(g)\Phi_{k,n}(h), \quad g, h \in G[k],
\]

\[
\Phi_{k,n}(U_k) = (x_{k,n,1}(U_k), \ldots, x_{k,n,r_k}(U_k)) = (1, \ldots, 1) \in F^{r_k},
\]

and therefore \( \Phi_{k,n} : G[k] \to F^{r_k} \) is an algebra homomorphism. We now prove its surjectivity. Clearly, \( \text{im}(\Phi_{k,n}) \) is a subalgebra of \( F^{r_k} \). By Lemma 5.11, we may assume that \( \text{im}(\Phi_{k,n}) \) has the form \( F^{(I_1, \ldots, I_s)} \) for some partition \( \{I_1, \ldots, I_s\} \) of \( [r_k] \). The pairwise linear independence of \( x_{k,n,i} \) for \( 1 \leq i \leq r_k \) implies that for any \( 1 \leq i_1 < i_2 \leq r_k \), we have \( x_{i_1} \neq x_{i_2} \), so there exists \( h \in G[k] \) such that \( x_{k,n,i_1}(h) \neq x_{k,n,i_2}(h) \). Since each \( I_i \neq \emptyset \), it follows that \( |I_i| = 1 \) for \( 1 \leq i \leq s \). Hence \( \text{im}(\Phi_{k,n}) = F^{(\{1\}, \ldots, \{r_k\})} = F^{r_k} \). We have shown that \( \Phi_{k,n} : G[k] \to F^{r_k} \) is surjective.

Next, by \( r_k \leq n - 1 \) and \( n \geq 2 \), clearly \( n \geq \max(2, r_k) \), so Lemma 5.10 applies. So we have

\[
\ker \Phi_{k,n} = \{ h \in G[k] \mid x_{k,n,i}(h) = 0, 1 \leq i \leq r_k \} = K_{[k]},
\]

where the first equality is by the definition of \( \Phi_{k,n} \), and the second equality is by Lemma 5.10. Note that by Lemma 5.4, we have \( K_{[k]} = G[k] \cap K \). Then \( \Phi_{k,n} : G[k] \to F^{r_k} \) factors through \( G[k] / \ker \Phi_{k,n} = G[k] / K_{[k]} = \hat{G}[k] \), inducing an algebra isomorphism

\[
\hat{\Phi}_{k,n} : \hat{G}[k] \to F^{r_k}, \quad \hat{\Phi}_{k,n}(h + K_{[k]}) = (x_{k,n,1}(h), \ldots, x_{k,n,r_k}(h)), \quad h \in G[k].
\]

It follows that \( \dim \hat{G}[k] = \dim F^{r_k} = r_k \). In particular, \( \hat{G}[k] \) is a finite dimensional algebra. Applying Lemma 2.3, we get \( \dim \hat{G}[k] = \dim \text{span}\{x_{k,n,i} : i = 1, \ldots, r_k\} \). Then \( \dim \text{span}\{x_{k,n,i} : i = 1, \ldots, r_k\} = r_k \) implying that \( x_{k,n,i} : 1 \leq i \leq r_k \), are linearly independent. (Note that we started off only assuming they are nonzero and pairwise linearly independent.) We formalize some of the results obtained above.

**Lemma 5.12.** Let \( k \geq 0 \). Assume there exists \( n = n_k \geq 2 \) such that \( r_k = \text{rk}_S T(f, k, n_k) \leq n_k - 1 \). Then the constructed map

\[
\tilde{\Phi}_{k,n} : \hat{G}[k] \to F^{r_k}, \quad \tilde{\Phi}_{k,n}(h + K_{[k]}) = (x_{k,n,1}(h), \ldots, x_{k,n,r_k}(h)), \quad h \in G[k].
\]

is an algebra isomorphism and \( \dim \hat{G}[k] = r_k \).

Composing \( \hat{\Phi}_k : \hat{G}[k] \to F^{r_k} \) with the canonical algebra isomorphism between \( \hat{G}[k] \) and \( \hat{G}[k] \) given in (5.2), we have an algebra isomorphism \( \hat{\Phi}_k : \hat{G}[k] \to F^{r_k} \). In particular, \( \dim \hat{G}[k] = \dim \hat{G}[k] = r_k \).

**Corollary 5.13.** With the same assumption as in Lemma 5.12, the map

\[
\hat{\Phi}_{k,n} : \hat{G}[k] \to F^{r_k}, \quad \hat{\Phi}_{k,n}(h + K_{[k]}) = (x_{k,n,1}(h), \ldots, x_{k,n,r_k}(h)), \quad h \in G[k].
\]

is an algebra isomorphism and \( \dim \hat{G}[k] = r_k \).

Note that if \( S \subseteq \mathbb{Z}_{\geq 0} \) is finite and \( |S| = k \), there are natural isomorphisms between \( \hat{G}(S) \) and \( \hat{G}[k] \) and also between \( \hat{G}(S) \) and \( \hat{G}[k] \), both resulting from any bijective map between \( S \) and \( [k] \). As a result, we conclude the following.

**Corollary 5.14.** Let \( k \geq 0 \) and \( S \subseteq \mathbb{Z}_{\geq 0} \) with \( |S| = k \). Suppose there exists some \( n = n_k \geq 2 \) so that \( \text{rk}_S T(f, k, n) \leq n - 1 \). Let \( r_k = \text{rk}_S T(f, k, n) \). Then \( \hat{G}(S) \cong \hat{G}(S) \cong F^{r_k} \) and \( \dim \hat{G}(S) = \dim \hat{G}(S) = r_k \). In particular, the value \( r_k \) is independent of the choice of \( n \).
5.3 One \( n \) implies for all \( n \)

Let \( n_k \) retain the same meaning as in Lemma 5.12, and let \( r = r_k = \text{rks}(T(f,k,n_k)) \). For any \( h \in \mathcal{G}[k] \), clearly \( h = hU_k^{n_k-1} \) so \( f(h) = f(hU_k^{n_k-1}) \). As \( x_{k,n_k,i}(U_k) = 1 \), \( 1 \leq i \leq r \),

\[
f(h) = f(hU_k^{n_k-1}) = (T(f,k,n_k))(h, U_k, \ldots, U_k) = \sum_{i=1}^{r} a_{k,n_k,i}(x_{k,n_k,i}(U_k))^{n_k-1} x_{k,n_k,i}(h)
\]

\[
= \sum_{i=1}^{r} a_{k,n_k,i} x_{k,n_k,i}(h)
\]

for any \( h \in \mathcal{G}[k] \). Hence \( f_{\mathcal{G}[k]} = \sum_{i=1}^{r} a_{k,n_k,i} x_{k,n_k,i} \), i.e., \( f_{\mathcal{G}[k]} \) is a linear combination of \( r \) algebra homomorphisms \( x_{k,n_k,i} : \mathcal{G}[k] \to \mathbb{F} \), for \( 1 \leq i \leq r \). In particular, applying to the product \( h_1 \cdots h_n \), for any \( n \geq 0 \) and any \( h_1, \ldots, h_n \in \mathcal{G}[k] \), (note that this \( n \) is arbitrary, not only for those \( n \) satisfying the requirements for the choice of \( n_k \))

\[
f(h_1 \cdots h_n) = \sum_{i=1}^{r} a_{k,n_k,i} x_{k,n_k,i}(h_1 \cdots h_n) = \sum_{i=1}^{r} a_{k,n_k,i} x_{k,n_k,i}(h_1) \cdots x_{k,n_k,i}(h_n).
\]

(When \( n = 0 \), we view it as \( f(U_k) = \sum_{i=1}^{r} a_{k,n_k,i} x_{k,n_k,i}(U_k) = \sum_{i=1}^{r} a_{k,n_k,i} \).) Hence

\[
T(f,k,n) = \sum_{i=1}^{r} a_{k,n_k,i} x_{k,n_k,i}^{\otimes n}
\]

for all \( n \geq 0 \). (When \( n = 0 \), (5.8) is still valid as \( T(f,k,0) = f(U_k) = \sum_{i=1}^{r} a_{k,n_k,i} = \sum_{i=1}^{r} a_{k,n_k,i} x_{k,n_k,i}^{\otimes 0} \) where the last equality is true as \( x_{k,n_k,i}^{\otimes 0} = 1 \).)

As shown before, \( x_{k,n_k,i} \) where \( 1 \leq i \leq r \) are linearly independent. Then by Lemma 2.4 applied to (5.8), we get \( \text{rks}(T(f,k,n)) = r \) for all \( n \geq 2 \); and the decomposition (5.8) is actually unique up to a permutation for \( n \geq 3 \).

**Theorem 5.15.** Let \( k \geq 0 \). Assume that for some \( n = n_k \geq 2 \), \( \text{rks}(T(f,k,n)) = r = n - 1 \). Then the following hold:

1. \( \text{rks}(T(f,k,n)) = r \) for every \( n \geq 2 \).
2. There exist \( r \) linearly independent algebra homomorphisms \( x_i : \mathcal{G}[k] \to \mathbb{F} \), and \( a_1, \ldots, a_r \in \mathbb{F} \setminus \{0\} \) such that \( f_{\mathcal{G}[k]} = \sum_{i=1}^{r} a_i x_i \); also for every \( n \geq 0 \),

\[
T(f,k,n) = \sum_{i=1}^{r} a_i x_i^{\otimes n}.
\]

Moreover, for any \( n \geq 3 \), any expression of \( T(f,k,n) \) as \( \sum_{i=1}^{r} b_i y_i^{\otimes n} \), where \( y_i : \mathcal{G}[k] \to \mathbb{F} \) are linear maps, is a permutation of the sum in (5.9).

We remark that this proves a nontrivial statement: The existence of some \( n_k \) has produced a uniform expression for the tensors \( T(f,k,n) \) all the way down to \( n = 0 \).
5.4 Putting things together

From now on, we assume that for every \( k \geq 0 \), there exist some \( n = n_k \geq 2 \) such that \( \text{rk}_S T(f, k, n) \leq n - 1 \). For every \( k \geq 0 \), we pick an arbitrary such \( n \), call it \( n_k \), and let \( r_k = \text{rk}_S T(f, k, n_k) \).

Having developed the theory in a more general setting, we can now follow the proof in [19] closely. We will be interested in the idempotent elements of \( \hat{G} \). For two elements \( p, q \in \hat{G} \), we say that \( q \) resolves \( p \), if \( pq = q \). We also say equivalently \( p \) is resolved by \( q \). It is clear that the binary relation \( \text{resolves} \) is antisymmetric and transitive and, when restricted to idempotents, reflexive. Furthermore, it is easy to see that the binary relation \( \text{resolves} \) on \( \hat{G} \) has the following properties:

1. The idempotent \( 0 = \mathcal{K} \) resolves everything and \( 1 = u_0 = U_0 + \mathcal{K} = K_0 + \mathcal{K} \) is resolved by everything.
2. If \( ab = 0 \) and \( c \) resolves both \( a \) and \( b \), then \( c = 0 \);
3. If \( a \) resolves \( b \), then \( c \) resolves \( a \) \iff \( c \) resolves \( ab \).

In the algebra \( \mathbb{F}^r \) \((r \geq 0)\), the idempotents are 0-1 tuples in \( \mathbb{F}^r \), and for idempotents \( q = (q_1, \ldots, q_r) \) and \( p = (p_1, \ldots, p_r) \), \( q \) resolves \( p \) \iff \( q_i = 1 \) implies \( p_i = 1 \).

Let \( S \) be a finite subset of \( \mathbb{Z}_{>0} \) with \(|S| = k \), and set \( r = r_k \) as above. By Corollary 5.14, \( \hat{G}(S) \cong \mathbb{F}^r \) as algebras, so \( \hat{G}(S) \) has a (uniquely determined idempotent) basis \( \mathcal{P}_S = \{p_1^S, \ldots, p_r^S\} \) such that \((p_i^S)^2 = p_i^S\) and \(p_i^S p_j^S = 0\) for \( i \neq j \). These correspond to the canonical basis \( \{e_i\}_{1 \leq i \leq r} \) of \( \mathbb{F}^r \) under this isomorphism. For \( i \neq j \), we have \((p_i^S, p_j^S) = (p_i^S, p_j^S) = 0 \). Furthermore, for all \( 1 \leq i \leq r \), \( f(p_i^S) = f((p_i^S)^2) = (p_i^S, p_i^S) \neq 0 \), otherwise \( \hat{G}(S) \) contains a nonzero element orthogonal to \( \hat{G}(S) \) with respect to the bilinear form \( \langle \cdot, \cdot \rangle \) restricted to \( \hat{G}(S) \times \hat{G}(S) \), contradicting Lemma 5.9.

We will call the elements \( p_i^S \in \mathcal{P}_S \) basic idempotents.

We denote by \( \mathcal{P}_{T,p} \) the set of all idempotents in \( \mathcal{P}_T \) that resolve a given element \( p \in \hat{G} \). If \( p \in \mathcal{P}_S \) and \( S \subset T \) and \(|T| = |S| + 1 \), then the number of elements in \( \mathcal{P}_{T,p} \) will be called the degree of \( p \in \mathcal{P}_S \), and denoted by \( \text{deg}(p) \). Obviously, this value is independent of which \(|S| + 1 \)-element superset \( T \) of \( S \) we take.

For any \( q \in \hat{G}(T) \), we have \( qu_{T \setminus S} = q \). It follows that for any \( S \subset T \) and \( p \in \hat{G} \), we have \( q \) resolves \( p \) \iff \( q \) resolves \( pu_{T \setminus S} \), since \( qp = qu_{T \setminus S}p = qpu_{T \setminus S} \). It is also important to point out that an element in \( \hat{G}(S) \) is an idempotent in \( \hat{G}(S) \) \iff it is an idempotent in \( \hat{G} \).

**Claim 5.16.** Let \( x \) be any idempotent element of \( \hat{G}(S) \). Then \( x \) is the sum of exactly those idempotents in \( \mathcal{P}_S \) that resolve it,

\[
x = \sum_{p \in \mathcal{P}_{S,x}} p.
\]

**Proof.** By the isomorphism \( \hat{G}(S) \cong \mathbb{F}^{|S|} \), every 0-1 tuple \( x = (x_1, \ldots, x_r) \in \mathbb{F}^r \) is the sum \( \sum x_i e_i \). \( \square \)

In particular

\[
u_S = \sum_{p \in \mathcal{P}_S} p, \quad \text{(5.10)}
\]

since \( u_S \in \hat{G}(S) \) corresponds to the all-1 tuple in \( \mathbb{F}^r \).

**Claim 5.17.** Let \( S \subset T \) be two finite sets. Then every \( q \in \mathcal{P}_T \) resolves exactly one element of \( \mathcal{P}_S \).
Proof. Consider the idempotents \( pu_T \setminus S \) (which could be 0) under the isomorphism \( \hat{G}(T) \cong \mathbb{F}^{\pi(T)} \), where \( p \in \mathcal{P}_S \). We can write the 0-1 tuple corresponding to \( pu_T \setminus S \) in \( \mathbb{F}^{\pi(T)} \) as the sum of those canonical basis 0-1 vectors. Recall that for any \( q \in \mathcal{P}_T \), \( q \) resolves \( p \) iff \( q \) resolves \( pu_T \setminus S \). Note that \( pu_T \setminus S \) must have disjoint positions with entry 1 for distinct \( p \in \mathcal{P}_S \), and the sum \( \sum_{p \in \mathcal{P}_S} pu_T \setminus S = u_S u_T = u_T \) is the all-1 tuple in \( \mathbb{F}^{\pi(T)} \). Thus each \( q \in \mathcal{P}_T \) resolves exactly one \( p \in \mathcal{P}_S \).

**Claim 5.18.** Let \( T \) and \( U \) be finite sets, and let \( S = T \cap U \). If \( x \in \hat{G}(T) \) and \( y \in \hat{G}(U) \), then

\[
    f(xy) = f(\hat{\pi}_S(x)y).
\]

**Proof.** For every \( T \)-labeled graph \( G_1 \) and \( U \)-labeled graph \( G_2 \), the graphs \( G_1 G_2 \) and \( \pi_S(G_1)G_2 \) are isomorphic as unlabeled graphs. Hence \( f(G_1 G_2) = f(\pi_S(G_1)G_2) \) as \( f \) ignores labels. Then we extend the equality from \( \mathcal{PLG} \) by linearity to \( \hat{G} \) and after that proceed to the quotient \( \hat{\mathcal{G}} = \mathcal{G}/\mathcal{K} \) using the definition of \( f \) on \( \hat{\mathcal{G}} \).

We have remarked earlier that \( f(p) \neq 0 \) for any \( p \in \mathcal{P}_S \).

**Claim 5.19.** Let \( S \subseteq T \) be two finite sets. If \( q \in \mathcal{P}_T \) resolves \( p \in \mathcal{P}_S \), then

\[
    \hat{\pi}_S(q) = \frac{f(q)}{f(p)} p.
\]

**Proof.** Note that \( q \in \hat{G}(T) \). Since \( S \subseteq T \), it follows that \( \hat{\pi}_S(q) \in \hat{G}(S) \). Because the only element from \( \hat{G}(S) \) orthogonal to \( \hat{G}(S) \) with respect to the dot product \( \langle \cdot, \cdot \rangle \) restricted to \( \hat{G}(S) \times \hat{G}(S) \) is 0 (by Lemma 5.9), it suffices to show that both sides give the same dot product with every basis element in \( \mathcal{P}_S \). For any \( p' \in \mathcal{P}_S \setminus \{p\} \), we have \( p'p = 0 \) so \( p'q = p'pq = 0 \). By Claim 5.18, this implies that

\[
    \langle p', \hat{\pi}_S(q) \rangle = f(p' \hat{\pi}_S(q)) = f(p'q) = 0 = \langle p', \frac{f(q)}{f(p)} p \rangle.
\]

Furthermore,

\[
    \langle p, \hat{\pi}_S(q) \rangle = f(p \hat{\pi}_S(q)) = f(pq) = f(q) = \langle p, \frac{f(q)}{f(p)} p \rangle.
\]

This proves the claim.

**Claim 5.20.** Let \( T \) and \( U \) be finite sets and let \( S = T \cap U \). Then for any \( p \in \mathcal{P}_S \), \( q \in \mathcal{P}_T \), and \( r \in \hat{G}(U) \) we have

\[
    f(qr) = \frac{f(q)}{f(p)} f(rp).
\]

**Proof.** By Claims 5.18 and 5.19,

\[
    f(qr) = f(\hat{\pi}_S(q)r) = \frac{f(q)}{f(p)} f(rp).
\]

**Claim 5.21.** Let \( T \) and \( U \) be finite sets and let \( S = T \cap U \). If both \( q \in \mathcal{P}_T \), \( r \in \mathcal{P}_U \) resolve \( p \in \mathcal{P}_S \), then \( qr \neq 0 \).
Proof. By Claim 5.20,
\[ f(qr) = \frac{f(q)}{f(p)} f(rp) = \frac{f(q)}{f(p)} f(r) \neq 0. \]
\[ \square \]

**Claim 5.22.** If \( S \subseteq T \), and \( q \in P_T \) resolves \( p \in \mathcal{P}_S \), then \( \deg(q) \geq \deg(p) \).

**Proof.** It suffices to show this in the case when \(|T| = |S| + 1\). Let \( U \subset \mathbb{Z}_{>0} \) be any \((|S| + 1)\)-element superset of \( S \) different from \( T \); suppose this is the disjoint union \( U = T \cup \{a\} \), \( a \notin T \). Let \( Y \) be the set of elements in \( P_U \) resolving \( pu_{\{a\}} \) (equivalently, resolving \( p \), because every \( r \in P_U \) resolves \( u_{\{a\}} \) as \( a \in U \)). Then \( pu_{\{a\}} = \sum_{r \in Y} r \) by Claim 5.16. Here \(|Y| = \deg(p)\). Furthermore, we have
\[ \sum_{r \in Y} qr = q \sum_{r \in Y} r = qpu_{\{a\}} = qu_{\{a\}}. \]  \[ (5.11) \]

Each term \( qr \) on the left hand side is nonzero by Claim 5.21, and since the terms are all idempotent, each of them is a sum of one or more elements of \( \mathcal{P}_{T \cup U} \). Furthermore, if \( r, r' \in Y \) \((r \neq r')\), then we have the orthogonality relation
\[ (qr)(qr') = q(rr') = 0, \]
so the sets of basic idempotents of \( \mathcal{P}_{T \cup U} \) in the expansion of each term are pairwise disjoint.

Therefore the expansion \( \sum_{r \in Y} qr \) in \( \mathcal{P}_{T \cup U} \) contains at least \(|Y| = \deg(p)\) terms. On the right hand side of (5.11), for any \( z \in \mathcal{P}_{T \cup U} \), \( z \) resolves \( q \) iff \( z \) resolves \( qu_{\{a\}} \) since \( a \in U \). Thus the number of terms in the expansion of \( qu_{\{a\}} \) in the basis \( \mathcal{P}_{T \cup U} \) is precisely \( \deg(q) \) by definition. Thus, \( \deg(q) \geq |Y| = \deg(p) \). The claim is proved. \[ \square \]

**5.5 Bounding the expansion**

At this point, we finally assume that all the conditions of Theorem 3.4 are satisfied, i.e., \( f(K_0) = 1 \) and there is an integer \( q \geq 0 \) such that for every \( k \geq 0 \) there exists \( n = n_k \geq 2 \) satisfying \( r_{k,n} = \text{rk}_S T(f,k,n) \leq \min(n-1,q^k) \). In particular \( r_{0,n} \leq q^0 = 1 \) for \( n = n_0 \geq 2 \). Clearly, \( r_{0,n} \neq 0 \) since \( f(K_0) = 1 \) so \( r_{0,n} = 1 \). By Proposition 3.1, \( f \) is multiplicative.

Next, from \( f(K_0) = 1 \), we have \( U_\emptyset = K_0 \notin \mathcal{K} \) so that \( u_\emptyset = U_\emptyset + \mathcal{K} \) is a nonzero identity in \( \hat{G}(\emptyset) = \hat{G}[0] \neq 0 \). As \( u_\emptyset \) is the sum of all basic idempotents in \( \hat{G}(\emptyset) \) we infer that \( \mathcal{P}_\emptyset \neq 0 \). Hence there is at least one basic idempotent.

If for any finite \( S \subseteq \mathbb{Z}_{>0} \), a basic idempotent \( p \in \mathcal{P}_S \) has degree \( D \geq 0 \), then for any superset \( T \subseteq \mathbb{Z}_{>0} \) of \( S \) with \(|T| = |S| + 1\), there are \( D \) basic idempotents resolving \( p \). Let \( S \subseteq T \), \( t = |T \setminus S| \), and \( T \setminus S = \{u_1,u_2,\ldots,u_t\} \). For each \( 1 \leq i \leq t \), we can pick \( D \) basic idempotents \( q_{ui}^\ell \in \mathcal{P}_{S \cup \{u_i\}} \) resolving \( p \), where \( 1 \leq j \leq D \). For any mapping \( \phi: \{1,\ldots,t\} \rightarrow \{1,\ldots,D\} \), we can form the product \( q_\phi = \prod_{i=1}^t q_{ui}^{\phi(i)} \). If \( t = 0 \), we assume \( q_\phi = p \). These are clearly idempotents resolving \( p \). If \( \phi \neq \phi' \) then for some \( i \), we have the orthogonality relation \( q_{ui}^{\phi(i)} q_{ui}^{\phi'(i)} = 0 \). Thus \( q_\phi q_{\phi'} = 0 \). Also by applying Claim 5.20 \( t \) times,
\[ f(q_\phi) = f(q_{\phi}p) = f\left(\prod_{i=1}^t q_{ui}^{\phi(i)}p\right) = \left(\prod_{i=1}^t f(q_{ui}^{\phi(i)})\right)f(p) \neq 0, \]  \[ (5.12) \]
and so \( q_\phi \neq 0 \). Thus the set \( \{q_\phi \mid \phi: \{1,\ldots,t\} \rightarrow \{1,\ldots,D\}\} \) is linearly independent. This implies that the dimension of \( \hat{G}(T) \) over \( \mathbb{F} \) is at least \( D^t = D^{|T| - |S|} \). But by Corollary 5.14 and the
hypothesis of Theorem 3.4 we also have the upper bound $q^{|T|}$. If $D > q$, this leads to a contradiction if $|T|$ is large. It follows that $D \leq q$, i.e., the degrees of basic idempotents for any $S$ and any $p \in \mathcal{P}_S$ are bounded by $q$. Let $D \geq 0$ denote the maximum degree over all such $S$ and $p \in \mathcal{P}_S$, and suppose it is attained at some particular $S$ and $p \in \mathcal{P}_S$. We now fix this $S$ and $p$. Note that for the existence of $D$ we also use the existence of a basic idempotent.

For $u \in \mathbb{Z}_{>0} \setminus S$, let $q^u_1, \ldots, q^u_D$ denote the elements of $\mathcal{P}_{S \cup \{u\}}$ resolving $p$. Note that for $u, v \in \mathbb{Z}_{>0} \setminus S$, there is a natural isomorphism between $\hat{\mathcal{G}}(S \cup \{u\})$ and $\hat{\mathcal{G}}(S \cup \{v\})$ (induced by the map that fixes $S$ pointwise and maps $u$ to $v$), and we may choose the indexing so that $q^u_i$ corresponds to $q^v_i$ under this isomorphism.

Now for any finite set $T \supseteq S$ all basic idempotents in $\mathcal{P}_T$ that resolve $p$ can be described. To describe these, let $V = T \setminus S$, and for every map $\phi : V \to \{1, \ldots, D\}$, we define as before

$$q_{\phi} = \prod_{v \in V} q^v_{\phi(v)}. \quad (5.13)$$

We have shown that these are linearly independent.

**Claim 5.23.**

$$\mathcal{P}_{T,p} = \{q_{\phi} : \phi \in \{1, \ldots, D\}^V\}. \quad \text{Proof.}$$

We prove this by induction on the cardinality of $V = T \setminus S$. For $|V| = 0, 1$ the assertion is trivial. Suppose that $|V| > 1$. Pick any $u \in V$, let $U = S \cup \{u\}$ and $W = T \setminus \{u\}$; thus $U \cap W = S$. By the induction hypothesis, the basic idempotents in $\mathcal{P}_W$ resolving $p$ are elements of the form $q_{\psi}$, for $\psi \in \{1, \ldots, D\}^W$.

Let $r$ be one of these. By Claim 5.21, $rq^u_i \neq 0$ for any $1 \leq i \leq D$, and clearly resolves $r$. We can write $rq^u_i$ as a sum of basic idempotents in $\mathcal{P}_T$ resolving it, and it is easy to see that these also resolve $r$ (as resolve is transitive). For each $rq^u_i$ the sum is nonempty as $rq^u_i \neq 0$. Furthermore, the sets of basic idempotents occurring in the expressions for $rq^u_i$ and $rq^u_j$ ($i \neq j$) are disjoint; this follows from item 2 stated at the beginning of this subsection, and $q^u_i q^u_j = 0$. If the sum for any $rq^u_i$ has more than one basic idempotent, then $r$ would have degree $> D$, violating the maximality of $D$. So each $rq^u_i$ must be a basic idempotent in $\mathcal{P}_T$ itself.

Each $r \in \mathcal{P}_W$ resolves $p$ iff $r$ resolves $pu_W$. Hence $pu_W = \sum_{r \in \mathcal{P}_{W,p}} r$. Also $pu_\{u\} = \sum_{i=1}^D q^u_i$. Therefore we have

$$pu_T = pu_W pu_\{u\} = \sum_{r \in \mathcal{P}_{W,p}, 1 \leq i \leq D} r q^u_i$$

i.e., the basic idempotents $rq^u_i$ ($r \in \mathcal{P}_{W,p}, 1 \leq i \leq D$) form the set of basic idempotents in $\mathcal{P}_T$ resolving $pu_T$, which is equivalent to resolving $p$. It follows that these are all the elements of $\mathcal{P}_{T,p}$. This proves the claim. \[\square\]

It is immediate from the definition that an idempotent $q_{\phi}$ resolves $q^u_i u_V$ (equivalently $q^v_i$) iff $\phi(v) = i$. Hence it also follows that

$$q^u_i u_V = \sum_{\phi : \phi(v) = i} q_{\phi}.$$  

By the same reason, it also follows that for $u, v \in V$, $u \neq v$, and any $1 \leq i, j \leq D$,

$$q^u_i q^v_j u_V = \sum_{\phi : \phi(u) = i, \phi(v) = j} q_{\phi}. \quad (5.14)$$  

21
5.6 Constructing the target graph

Now we can define $H$ as follows. Let $S$ and $p$ be fixed as above. For any $u \in \mathbb{Z}_{>0} \setminus S$, let $\{q_1^u, \ldots, q_D^u\}$ be defined as in subsection 5.5.

Let $H$ be the looped complete graph on $V(H) = \{1, \ldots, D\}$. We have to define the node weights and edge weights. For every $i \in V(H)$, let

$$\alpha_i = \frac{f(q_i^u)}{f(p)}$$

be the weight of node $i$. This definition does not depend on the choice of $u$, because if $v \in \mathbb{Z}_{>0} \setminus S$ and $v \neq u$, then the isomorphism from $\hat{G}(S \cup \{u\})$ to $\hat{G}(S \cup \{v\})$ (induced by the map that fixes $S$ and maps $u$ to $v$), will send $q_i^u$ to $q_i^v$.

Let $u, v \in \mathbb{Z}_{>0} \setminus S$, $u \neq v$, and let $W = S \cup \{u, v\}$. Let $K_{uv}$ denote the graph on the vertices $u$ and $v$ that are correspondingly labeled $u$ and $v$, and has only one edge connecting $u$ and $v$. Let $k_{uv} = K_{uv} + \mathcal{K}$ denote the corresponding element of $\hat{G}(\{u, v\})$. We can express $pk_{uv}$ as a linear combination of the basic idempotents from $\mathcal{P}_W$. Note that $r \in \mathcal{P}_W$ resolves $p$ iff $r$ resolves $pu_{\{u,v\}}$, thus $pu_{\{u,v\}} = \sum r \in \mathcal{P}_W \ r$. So if $r' \in \mathcal{P}_W \setminus \mathcal{P}_{WP}$, we have $r'p = r'u_{\{u,v\}}p = 0$. Thus $r'pk_{uv} = 0$. It follows that $pk_{uv}$ is a linear combination of the basic idempotents from the subset $\mathcal{P}_{W,p}$. We write this unique expression

$$pk_{uv} = \sum_{i,j=1}^D \beta_{ij} q_i^u q_j^v.$$

This defines (by the uniqueness) the weight $\beta_{ij}$ of the edge $ij$. Note that $\beta_{ij} = \beta_{ji}$ for all $i, j$, since $pk_{uv} = pk_{vu}$.

We prove that this weighted graph $H$ gives the desired homomorphism function.

**Claim 5.24.** For every finite graph $G$, $f(G) = \text{hom}(G, H)$.

**Proof.** Let $V$ be a finite subset of $\mathbb{Z}_{>0}$ disjoint from $S$ of cardinality $|V(G)|$. We label $V(G)$ by $V$ thus making $G$ a $V$-labeled graph, so now $G \in \mathcal{G}(V)$. Since $f$ ignores labels, we may identify $V$ and $V(G)$, and assume $V(G) = V$. Now we take $T = S \cup V$, thus $V = T \setminus S$. This defines $q_\phi$ as in subsection 5.5. By (5.14), we have for each pair $u, v$ of distinct elements of $V(G)$,

$$pk_{uv} = \sum_{i,j \in V(H)} \beta_{ij} q_i^u q_j^v u_v = \sum_{i,j \in V(H)} \beta_{ij} \sum_{\phi : \phi(u) = i, \phi(v) = j} q_\phi = \sum_{\phi \in V(H)^V} \beta_{\phi(u), \phi(v)} q_\phi.$$

Here to define the set of mappings $\phi$ we take $T = S \cup V$, thus $V = T \setminus S$. Then the last equality follows from the fact that

$$\{\phi : V \to V(H)\} = \bigcup_{i, j \in V(H)} \{\phi \in V(H)^V : \phi(u) = i, \phi(v) = j\}$$

is a partition. Let $g = G + \mathcal{K}$ be the corresponding element of $G$ in $\hat{G}(V)$. Clearly $G = (\prod_{uv \in E(G)} K_{uv}) U_V$ so $g = (\prod_{uv \in E(G)} k_{uv}) u_V$. (When $E(G) = \emptyset$, we view it as $G = U_V$ so $g = u_V$.)

---

\footnote{For $F = \mathbb{R}$, if we require the positive semidefiniteness of the connection matrices $M(f, k)$ for $k \geq 0$, then since $p$ and $q_i^u$ are basic idempotents, $f(p) = f(p^2) > 0$ and similarly $f(q_i^u) > 0$. Thus $\alpha_i > 0$, and so we recover the positive vertex weight case; see [19].}
We have \( f(G) = f(g) \) by the definition of \( f \) on \( \hat{G} \). Also note that \( gu_V = g \) so \( g = gu_V^{\left|E(G)\right|} \). Also, \( p \) is an idempotent so \( p = p^{\left|E(G)\right|+1} \). Then

\[
pg = p^{\left|E(G)\right|} \cdot gu_V^{\left|E(G)\right|} = p\left( \prod_{u \in E(G)} p k_{uv} u v \right) u V = p\left( \prod_{u \in E(G)} \left( \sum_{\phi \in \mathcal{V}(H)^V} \beta_{\phi(u),\phi(v)} \right) \right) u V.
\]

(When \( E(G) = \emptyset \), this is simply \( pg = pu V \).) Note that when we expand the product of sum as a sum of products, for any two edges \( u v \in E(G) \) and \( u' v' \in E(G) \), if the mappings \( \phi \) and \( \phi' \in \mathcal{V}(H)^V \) (in the respective sums) disagree on any vertex of \( V = V(G) \), the product \( q_{\phi} q_{\phi'} = 0 \). This implies that in the sum of products expression we only sum over all \( \phi \in \mathcal{V}(H)^V \) (and not over the \( |E(G)| \)-tuples of these). Also \( q_{\phi} \) resolves \( p \), so \( pq_{\phi} = q_{\phi} \). Moreover, each \( q_{\phi} \in \hat{G}(S \cup V) \) so \( q_{\phi} u V = q_{\phi} \). This implies that

\[
pg = \left( \sum_{\phi : V \rightarrow V(H)} \left( \prod_{u \in E(G)} \beta_{\phi(u),\phi(v)} \right) \right) u V = \sum_{\phi : V \rightarrow V(H)} \left( \prod_{u \in E(G)} \beta_{\phi(u),\phi(v)} \right) u V.
\]

(When \( E(G) = \emptyset \), we view it as \( pg = pu V = \sum_{\phi : V \rightarrow V(H)} q_{\phi} = \sum_{\phi : V \rightarrow V(H)} \left( \prod_{u \in E(G)} \beta_{\phi(u),\phi(v)} \right) q_{\phi} \).

which is true by Claims 5.16 and 5.23 with \( T = S \cup V \) and the fact that an element \( h \in \hat{G}(S \cup V) \) resolves \( p \) if and only if it resolves \( pu V \). Note that \( p \in \hat{G}(S) \) and has a representative in \( \hat{G}(S) \) as a linear combination of labeled graphs from \( P \mathcal{L} G(S) \), \( g \in \hat{G}(V) \) has the representative \( G \in \mathcal{P} \mathcal{L} G(V) \subseteq \hat{G}(V) \), and \( S \cap V = \emptyset \). Hence \( f(p) f(g) = f(pg) \), as \( f \) is multiplicative, \( f \) ignores labels and also by the definition of \( f \) on \( \hat{G} \). Therefore by (5.12) and (5.13),

\[
f(p) f(g) = f(p) f(g) = f(pg) = \sum_{\phi : V \rightarrow V(H)} \left( \prod_{u \in E(G)} \beta_{\phi(u),\phi(v)} \right) f(q_{\phi}).
\]

Since \( f(p) \neq 0 \), we can cancel it on both sides, and complete the proof.

**Remark:** Note that if \( D = 0 \), then from the proof we get that \( H \) is the empty graph, so \( f(G) = 0 \) unless \( G = K_0 \) (the empty graph) and \( f(K_0) = 1 \). After that, we trivially get \( \hat{G}(T) = 0 \) for any \( T \neq \emptyset \) and \( \hat{G}(\emptyset) \cong \mathbb{F} \) as algebras. However, \( p \in \mathcal{P} \mathcal{S} \) so it follows that \( S = \emptyset \). Therefore by the previous isomorphism \( \mathcal{P}_\emptyset = \{ p \} \) so \( p \) is the only basic idempotent in \( \hat{G}(\emptyset) \) and so in the entire \( \hat{G} \).

\[\square\]

## 6 More Applications

### 6.1 Tensor rank lower bound of certain tensors

We first prove a lemma about \( \mathcal{M}_{n:a,b} \in \text{Sym}^n(\mathbb{F}^2) \), which was defined in Section 4. Below is a restatement of Lemma 4.1; the proof is adapted from the proof of Lemma 5.1 in [15].

**Lemma 6.1.** If \( b \neq 0 \) and \( n \geq 0 \), then \( r_k \mathcal{M}_{n:a,b} \geq n \).

**Proof.** For \( n = 0 \) the lemma is trivial. Let \( n \geq 1 \). Clearly \( \mathcal{M}_{n:a,b} \neq 0 \), and so \( r = r_k \mathcal{M}_{n:a,b} \geq 1 \). Suppose \( r < n \) for a contradiction. Then we can write \( \mathcal{M}_{n:a,b} = \sum_{i=1}^{\lambda} \lambda_i v_i^{\otimes n} \) where \( \lambda_i \in \mathbb{F} \), and
Let $v_i = (\alpha_i, \beta_i) \in \mathbb{F}^2$ be nonzero and pairwise linearly independent. The decomposition implies that the linear system $Ax = \vec{b}$ with the extended matrix

$$
\tilde{A} = [A | \vec{b}] = \begin{bmatrix}
\alpha_1^n & \alpha_2^n & \ldots & \alpha_r^n \\
\alpha_1^{n-1} \beta_1 & \alpha_2^{n-1} \beta_2 & \ldots & \alpha_r^{n-1} \beta_r \\
\alpha_1^{n-2} \beta_1^2 & \alpha_2^{n-2} \beta_2^2 & \ldots & \alpha_r^{n-2} \beta_r^2 \\
\vdots & \vdots & \ddots & \vdots \\
\beta_1^n & \beta_2^n & \ldots & \beta_r^n \\
\end{bmatrix}
$$

has a solution $x_i = \lambda_i$, $1 \leq i \leq r$. Note that $\tilde{A}$ is $(n+1) \times (r+1)$ and $A$ has only $r$ columns. We show that rank $A = r+1 > \text{rank } A$. This is a contradiction.

1. All $\beta_i \neq 0$. Then $\alpha_i / \beta_i$ are pairwise distinct. Then the last $r$ rows of $A$, i.e., rows $n-r+2$ to $n+1$ form an $r \times r$ Vandermonde matrix of rank $r$. Note that $n+1 \geq n-r+2 = 2$. By $b \neq 0$, we get an $(r+1) \times (r+1)$ submatrix of $\tilde{A}$ of rank $r+1$ by taking row 2 and the last $r$ rows.

2. Some $\beta_i = 0$. Without loss of generality we can assume it is $\beta_1$. Then all other $\beta_i \neq 0$, and all $\alpha_i / \beta_i$ are pairwise distinct for $2 \leq i \leq r$. Then since $b \neq 0$, the submatrix of $\tilde{A}$ formed by taking rows 1, 2 and the last $r-1 \geq 0$ rows have rank $r+1$.

We now show that for an infinite field $\mathbb{F}$, we can give a tight upper bound for $\text{rk}_S M_{n;a,b}$ where $b \neq 0$ and $n \geq 1$. The existence of a decomposition $M_{n;a,b} = \sum_{i=1}^{r} \lambda_i v_i^{\otimes n}$ where $r \geq 1$, $\lambda_i \in \mathbb{F}$ and $v_i = (\alpha_i, \beta_i) \in \mathbb{F}^2$ (1 \leq i \leq r) is equivalent to the statement that system (6.1) has a solution $x_i = \lambda_i$ ($1 \leq i \leq r$). Note that by Lemma 6.1, we must have $r \geq n$.

Assume $\mathbb{F}$ is infinite. We show how to achieve $r = n$ with one exceptional case. First, we set all $\beta_i = 1$. By comparing with the Vandermonde determinant $\det[\tilde{A} | \vec{b}]$ as a polynomial in $t$, where the last column is $\vec{t} = (t, t^{n-1}, \ldots, t, 1)^T$, we see that

$$
\det \tilde{A} = \det([A | \vec{b}]) = (-1)^n \prod_{1 \leq i < j \leq n} (\alpha_i - \alpha_j) \cdot (a - b \sum_{i=1}^{n} \alpha_i).
$$

If we set $\alpha_1, \ldots, \alpha_n \in \mathbb{F}$ to be pairwise distinct, and $\sum_{i=1}^{n} \alpha_i = a/b$, then rank $A = \text{rank } \tilde{A} = n$.

The (affine) hyperplane $\Pi : \sum_{i=1}^{n} \alpha_i = a/b$, has points away from its intersections with finitely many hyperplanes $x_i = x_j$ ($i \neq j$), as long as each of these hyperplanes is distinct from $\Pi$. This is trivially true if $n = 1$. Let $n \geq 2$. Under an affine linear transformation we may assume $\Pi$ is the hyperplane $x_n = 0$ in $\mathbb{F}^n$ and we only need to show $\mathbb{F}^{n-1}$ is not the union of finitely many, say $k$, affine hyperplanes. Consider the cube $S^{n-1}$ for a large subset $S \subseteq \mathbb{F}$. The union of these $k$ affine hyperplanes intersecting $S^{n-1}$ has cardinality at most $k|S|^{n-2} < |S|^{n-1}$, for a large $S$.

Each hyperplane $x_i = x_j$ ($i \neq j$) is distinct from $\Pi$, except in one case

$$
a = 0, \quad n = 2, \quad \text{and } \text{char } \mathbb{F} = 2. \quad (6.2)
$$

In this exceptional case, we can easily prove that indeed $\text{rk}_S M_{2;0,b} = 3$.

We have proved

**Lemma 6.2.** If $\mathbb{F}$ is infinite, $b \neq 0$ and $n \geq 1$, then $\text{rk}_S M_{n;a,b} = n$ with one exception (6.2). In that exceptional case, $\text{rk}_S M_{2;0,b} = 3$. 

24
We remark that for any infinite $\mathbb{F}$ not in case (6.2), for $n \geq 2$ we can achieve $\text{rank } A = \text{rank } \hat{A} = n$ in (6.1) by further requiring that all $\alpha_i \neq 0$ (in addition to being pairwise distinct, and all $\beta_i = 1$.) This is simply to avoid the intersections of $\mathbf{\Pi}$ with another finitely many hyperplanes distinct from $\mathbf{\Pi}$. Setting $a_i = 1/\alpha_i$, we can set $a_i \in \mathbb{F}$ such that $\text{rank } A = \text{rank } \hat{A} = n$ for the following $\hat{A}$.

$$
\hat{A} = [A | \hat{b}] = \begin{bmatrix}
1 & 1 & \ldots & 1 & a \\
 a_1 & a_2 & \ldots & a_n & 1 \\
 \vdots & \vdots & \ddots & \vdots & \vdots \\
a_1^{n-1} & a_2^{n-1} & \ldots & a_n^{n-1} & 0 \\
a^n_1 & a^n_2 & \ldots & a^n_n & 0
\end{bmatrix}.
$$

(6.3)

The linear system $Ax = \hat{b}$ has a solution $(\lambda_1, \ldots, \lambda_n)$ implies that $M_{m;a,b} = \sum_{i=1}^n \lambda_i v_i^{\otimes m}$, where $v_i = (1, a_i)$, for all $0 \leq m \leq n$. (For $m = 0$, $M_{0;a,1} = a$ is a constant, and $v_i^{\otimes 0} = 1$.)

In Section 4 we discussed $\#\text{PERFECT-MATCHING}$ (pm). Here we continue the discussion on $\#\text{WEIGHTED-MATCHING}_a$ and other Holant problems, including proper edge colorings and vertex-disjoint cycle covers.

### 6.2 Weighted matchings

We prove that the problem $\#\text{WEIGHTED-MATCHING}_a$ defined by $\text{wm}_a(G) = \text{Holant}(G; \{M_{m;a,1}\}_{n \geq 0})$ is not expressible as a GH function over any field, for any $a$.

Clearly, $\text{wm}_a$ is a multiplicative graph parameter with $\text{wm}_a(K_0) = 1$. If $a = 0$ then $\text{wm}_a$ is just $\#\text{PERFECT-MATCHING}$ (pm). Counting all matchings is $\text{wm}_a$ for $a = 1$.

Let $G$ be a $k$-labeled graph, $X \subseteq [k]$, and let $\text{wm}_a(G, X)$ denote the partial Holant sum in $\text{wm}_a(G)$ over all $\{0,1\}$-edge assignments of $G$ such that within $[k]$, those in $X$ have exactly one incident edge assigned 1 and all nodes in $[k] \setminus X$ have no incident edges assigned 1. Then we have for any $k$-labeled graphs $G_1, \ldots, G_n$,

$$
\text{wm}_a(G_1 \cdots G_n) = \sum_{X_1 \sqcup \ldots \sqcup X_n \subseteq [k]} a^{k - |X_1| \ldots |X_n|} \text{wm}_a(G_1, X_1) \cdots \text{wm}_a(G_n, X_n).
$$

This means that $T(\text{wm}_a, k, n)$ is the product $N_{k;a}^\otimes n W_{k,n;a}$, where $N_{k;a}$ has infinitely many rows indexed by all $k$-labeled graphs $G$, and $2^k$ columns indexed by $X \subseteq [k]$, with the entry at $(G, X)$

$$
N_{k;a;G,X} = \text{wm}_a(G, X),
$$

and $W_{k,n;a}$ is a symmetric $2^k \times \ldots \times 2^k$ tensor (from $\text{Sym}^n(\mathbb{F}^{2^k}))$, where

$$
W_{k,n;a;X_1, \ldots, X_n} = \begin{cases} a^{k - |X_1| \ldots |X_n|} & \text{if } X_1 \cup \ldots \cup X_n \subseteq [k], \\ 0 & \text{otherwise.} \end{cases}
$$

Hence $\text{rk}_S T(\text{wm}_a, k, n) \leq \text{rk}_S W_{k,n;a}$. We show that in fact equality holds. Consider the same family of $k$-labeled graphs $\{P_X\}_{X \subseteq [k]}$ defined in Section 4. It is easy to see that for $X, Y \subseteq [k]$, $N_{k;a,P_X,Y} = a^{|X| - |Y|}$ if $Y \subseteq X$ and 0 otherwise. Here by convention, $a^0 = 1$ even if $a = 0$. Consider the rows in $N_{k;a}$ corresponding to $\{P_X\}_{X \subseteq [k]}$. They form the nonsingular matrix $[1 0] \otimes^n
if the rows and columns are ordered lexicographically for \(X, Y \subseteq [k]\). Therefore \(\text{rk}_S W_{k,n;a} = \text{rk}_S \left( \left[ \begin{array}{c} 1 \end{array} \right] \otimes^n W_{k,n,a} \right) \leq \text{rk}_S T(wm_a, k, n)\) and so \(\text{rk}_S T(wm_a, k, n) = \text{rk}_S W_{k,n;a}\).

Note that for \(k = 1\), \(W_{1,n;a} = M_{n,a,1} = [a, 1, 0, \ldots, 0] \in \text{Sym}^n(\mathbb{F}^2)\) where \(n \geq 1\). Applying Lemma 6.1 with \(b = 1\), we get \(\text{rk}_S W_{1,n;a} \geq n\) and therefore \(\text{rk}_S T(wm_a, 1, n) \geq n\) for \(n \geq 1\). Now if \(wm_a\) were expressible as \(\text{hom}(\cdot, H)\) for some weighted graph \(H\) with \(q = |V(H)|\), then by Theorem 3.2, \(\text{rk}_S T(wm_a, k, n) \leq q^k\) for \(k, n \geq 0\) so that \(\text{rk}_S T(wm_a, 1, n) \leq q\) for \(n \geq 0\). This contradicts \(\text{rk}_S T(wm_a, 1, n) \geq n\) when \(n > q\). Hence \(wm_a\) is not expressible as a graph homomorphism function over any field.

By the same remark for Theorem 4.2, the proof for Theorem 6.3 carries over to simple graphs.

**Theorem 6.3.** The graph parameter \(#\text{WEIGHTED-MATCHING} (wm_a)\) where \(a \in \mathbb{F}\) as a function defined on simple graphs is not expressible as a graph homomorphism function over any field \(\mathbb{F}\).

6.3 Bounded degree graphs

Fix any \(d \geq 2\). A degree-\(d\) bounded graph is a graph with maximum degree at most \(d\). In this subsection, we investigate the expressibility of the graph parameter \(#\text{WEIGHTED-MATCHING}_a\) \((wm_a)\) as a GH function on bounded degree graphs. More precisely, we are interested when \(wm_a\) is expressible as \(\text{hom}(\cdot, H)\) with \(|V(H)| = q\) on degree-\(d\) bounded graphs. For convenience, we temporarily allow vertex weights to be \(0\), and it will be addressed later.

Given a graph \(G\) (possibly with multiple edges but no loops), let \(G'\) be the vertex-edge incidence graph of \(G\). The vertex set \(V(G')\) consists of the original vertices from \(V(G)\) on the LHS and the edges \(E(G)\) on the RHS. Let \(H\) be the weighted graph specified by vertex weights \((\alpha_1, \ldots, \alpha_q) \in \mathbb{F}^q\) and a symmetric matrix \(B = (\beta_{ij}) \in \mathbb{F}^{q \times q}\) for edge weights, then for any \(G\)

\[
\text{hom}(G, H) = \text{Holant}(G'; \sum_{i=1}^q \alpha_i e_{q,i}^{\otimes n} | B),
\]

where \(\{e_{q,i}\}_{i=1}^q \in \mathbb{F}^q\) has a single \(1\) at the \(i\)-th position and \(0\) elsewhere. Here \(\text{hom}(G, H)\) is expressed in (6.4) as a domain-\(q\) Holant sum on \(G'\): any LHS vertex of \(G'\) of degree \(n\) is assigned the signature \(\sum_{i=1}^q \alpha_i e_{q,i}^{\otimes n}\) (which takes value \(\alpha_i\) if all incident edges have value \(i \in [q]\), and \(0\) otherwise), and any RHS vertex of \(G'\) (an edge of \(G\)) is assigned the symmetric binary signature specified by \(B\).

First, we show that for any \(a \in \mathbb{F}\), if \(wm_a\) is expressible as \(\text{hom}(\cdot, H)\) with \(|V(H)| = q\) on degree-\(d\) bounded simple graphs over any field \(\mathbb{F}\), then \(q \geq d\). Recall the proof from Section 6.2. This time we restrict the connection tensor \(T(wm_a, 1, d)\) (for \(k = 1\)) to the 1-labeled graphs \(P_0\) and \(P_{[1]}\), which are just \(K_1\) and \(K_2\) without the label. The product of \(d\) labeled graphs from \(\{P_0, P_{[1]}\}\) having \(\ell\) copies of \(P_{[1]}\) is the star graph \(S_\ell\) with one internal node labeled by \(1\) and \(\ell\) external unlabeled nodes. All these are degree-\(d\) bounded simple graphs. Note that \(T(wm_a, 1, d)_{\{P_0, P_{[1]}\}} = [1, 0]^\otimes d W_{1,d,a}\). Therefore \(\text{rk}_S \left( T(wm_a, 1, d)_{\{P_0, P_{[1]}\}} \right) = \text{rk}_S \left( [1, 0]^\otimes d W_{1,d,a} \right) \geq d\), the last step is by Lemma 6.1. On the other hand, if \(wm_a\) is expressible as \(\text{hom}(\cdot, H)\) with \(|V(H)| = q\) on degree-\(d\) bounded simple graphs, then arguing similarly to the proof of Theorem 3.2 but restricting the domain of the arguments \(G_i, 1 \leq i \leq d\) in (3.3) to \(\{P_0, P_{[1]}\}\), we have \(\text{rk}_S \left( T(wm_a, 1, d)_{\{P_0, P_{[1]}\}} \right) \leq q\) so \(d \leq q\). Then clearly this bound also holds if we do not allow 0-weighted vertices.

Now let \(\mathbb{F}\) be infinite. By the remark after Lemma 6.2, if we are not in the exceptional case (6.2) (we put \(n = d\)), then for some \(a_i, \alpha_i \in \mathbb{F}\) we have \(M_{m,a,1} = \sum_{i=1}^d \alpha_i (1, a_i)^{\otimes m}\), for every \(0 \leq m \leq d\).
Let $T \in \mathbb{F}^{d \times 2}$ be the matrix whose 1st and 2nd columns are $(1, 1, \ldots, 1)^T$ and $(a_1, a_2, \ldots, a_d)^T$ respectively. Then $e_{d,i}T = (1, a_i)$. Define the symmetric matrix $B = (\beta_{ij}) = TT^T \in \mathbb{F}^{d \times d}$. Now let $H$ be a weighted graph on $d$ vertices specified by $(\alpha_1, \ldots, \alpha_d) \in \mathbb{F}^d$ and $B = (\beta_{ij}) \in \mathbb{F}^{d \times d}$. Then for any degree-$d$ bounded graph $G$ we have the following equality chain:

$$\text{wm}_a(G) = \text{Holant}(G; \{M_{m;a,1}\}_{0 \leq m \leq d}) = \text{Holant}(G'; \{M_{m;a,1}\}_{0 \leq m \leq d} | (=2))$$

$$= \text{Holant}(G'; \{\sum_{i=1}^d \alpha_i (1, a_i)^\otimes m\}_{0 \leq m \leq d} | (=2)) = \text{Holant}(G'; \{\sum_{i=1}^d \alpha_i (e_{d,i}T)^\otimes m\}_{0 \leq m \leq d} | (=2))$$

$$= \text{Holant}(G'; \{\sum_{i=1}^d \alpha_i e_{d,i}^\otimes m T^\otimes m\}_{0 \leq m \leq d} | (=2)) = \text{Holant}(G'; \{\sum_{i=1}^d \alpha_i e_{d,i}^\otimes m\}_{0 \leq m \leq d} | T^\otimes 2(=2)),
$$

where the last equation moving $T^\otimes n$ from the left-hand side of the Holant problem to $T^\otimes 2$ in the right-hand side, is called a holographic transformation [33, 5]. This follows from the associativity of the operation of tensor contraction. The EQUALITY function $(=2)$ is transformed to $T^\otimes 2(=2)$, which has the matrix form $TT^T = B$. Hence this is precisely the function $\text{hom}(G, H)$. We have temporarily allowed 0-weighted vertices; but in fact by the lower bound $q \geq d$ no 0-weighted vertex exists, since otherwise by removing 0-weighted vertices we would have $\text{wm}_a(\cdot) = \text{hom}(\cdot, H')$ with fewer vertices.

The inexpressibility with $|V(H)| = 2$ for the exceptional case (6.2) holds even for simple graphs, by considering paths of 0, 1 or 2 edges. Also, in this case it can be easily shown that $\text{wm}_a = \text{pm}$ is expressible as $\text{hom}(\cdot, H)$ where $|V(H)| = 3$: this can be done similarly to the expressibility proof above via a holographic transformation (then $H$ cannot have 0-weighted vertices).

This proves Theorem 6.4.

**Theorem 6.4.** Let $\mathbb{F}$ be a field and $d \geq 2$. Then for the graph parameter #\text{Weighted-Matching}_a (\text{wm}_a) where $a \in \mathbb{F}$ as a function defined on degree-$d$ bounded graphs the following hold:

1. \text{wm}_a is not expressible as $\text{hom}(\cdot, H)$ with $|V(H)| < d$ even on degree-$d$ bounded simple graphs.
2. If $\mathbb{F}$ is infinite, then $\text{wm}_a$ is expressible as $\text{hom}(\cdot, H)$ with $|V(H)| = d$, with one exception (6.2) in which case the minimal value for $|V(H)|$ is 3.

Note that #\text{Perfect-Matching (pm)} is just the special case $a = 0$. Hence Theorem 6.4 also holds for (pm) which proves Theorem 4.3.

### 6.4 Proper edge $d$-colorings

Next we show that the graph parameter #d-\text{Edge-Coloring} (ec_d) is not expressible as a GH function over any field of characteristic 0. Given a graph $G$, $ec_d(G)$ counts the number of proper edge $d$-colorings in a graph, where $d \geq 1$ is the number of colors available.

Clearly, ec_d is a multiplicative graph parameter with $ec(K_0) = 1$. Since char $\mathbb{F} = 0$, $\mathbb{F}$ is infinite. Consider $K_1$ as a 1-labeled graph and the star graph $S_d$ with one internal node labeled by 1 and $d$ unlabeled external nodes all connected to node 1, where $d \geq 1$. Consider the connection tensor $T(ec_d, k, n)$ restricted to $\{K_1, S_d\}^n$. For $(G_1, \ldots, G_n) \in \{K_1, S_d\}^n$, if more than one $G_i = S_d$ then the product $G_1 \cdots G_n$ has no proper edge $d$-coloring because the labeled vertex has degree $\geq 2d > d$. Then it is easy to see that the connection tensor $T(ec_d, k, n)$ restricted to $\{K_1, S_d\}^n$ has the form $\mathcal{M}_{1,d} = [1, d!, 0, \ldots, 0] \in \text{Sym}^n(\mathbb{F}^2)$, and $d! \neq 0$ in $\mathbb{F}$ as char $\mathbb{F} = 0$. Therefore by Lemma 6.1, rk$\mathcal{S} \mathcal{M}_{1,d} \geq n$ for $n \geq 1$. Hence rk$\mathcal{S} T(ec_d, 1, n) \geq n$ for $n \geq 1$. 27
Now if \( ec_d \) were expressible as \( \text{hom}(\cdot, H) \) for some weighted graph \( H \) with \( q = |V(H)| \), then by Theorem 3.2, \( \text{rk}_S T(ec_d, 1, n) \leq q \) for \( n \geq 0 \). This contradicts the upper bound when \( n > q \). Hence \( ec_d \) is not expressible as a graph homomorphism function over any field \( \mathbb{F} \) of \( \text{char} \mathbb{F} = 0 \).

By the same remark for Theorem 4.2, the proof for Theorem 6.5 carries over to simple graphs.

**Theorem 6.5.** The graph parameter \#d-EDGE-COLORING \( (ec_d) \) with \( d \geq 1 \) as a function defined on simple graphs is not expressible as a graph homomorphism function over any field of characteristic 0.

### 6.5 Vertex-disjoint cycle covers

We show that the graph parameter \( \text{vdcc} \) \( (#\text{VERTEX-DISJOINT-CYCLE-COVER}) \) which counts the number of vertex disjoint cycle covers in a graph is not expressible as a GH function over an arbitrary field. In a multigraph without loop a cycle is a vertex disjoint closed path of length at least 2. The graph parameter \( \text{vdcc}(G) = m \cdot 1 \in \mathbb{F} \), where \( m \) is the number of edge subsets \( E' \) that form a vertex disjoint set of cycles that cover all vertices.

Clearly, \( \text{vdcc} \) is a multiplicative graph parameter with \( \text{vdcc}(K_0) = 1 \). Next, consider \( K_1 \) and \( K_3 \) as 1-labeled graphs. Note that \( K_3 \) is a cycle of 3 vertices. It is easy to see that the connection tensor \( T(\text{vdcc}, k, n) \) restricted to \( \{K_1, K_3\}^n \) has the form \( M_{0,1} = [0, 1, 0, \ldots, 0] \in \text{Sym}^n(\mathbb{F}^2) \) and therefore by Lemma 6.1, \( \text{rk}_S M_{0,1} \geq n \) for \( n \geq 1 \). Hence \( \text{rk}_S T(\text{vdcc}, 1, n) \geq n \) for \( n \geq 1 \).

Now if \( \text{vdcc} \) were expressible as \( \text{hom}(\cdot, H) \) for some weighted graph \( H \) with \( q = |V(H)| \), then by Theorem 3.2, \( \text{rk}_S T(\text{vdcc}, 1, n) \leq q \) for \( n \geq 0 \). This contradicts the upper bound when \( n > q \). Hence \( \text{vdcc} \) is not expressible as a GH function over any field.

By the same remark for Theorem 4.2, the proof for Theorem 6.6 carries over to simple graphs.

**Theorem 6.6.** The graph parameter \#\text{VERTEX-DISJOINT-CYCLE-COVER} (\( \text{vdcc} \)) as a function defined on simple graphs is not expressible as a graph homomorphism function over any field.

### 7 Extensions

So far we have allowed \( G \) to have multiple edges but no loops as is the standard definition. We can extend the results in this paper to more general graphs. If we allow (multiple) loops in \( G \), we can show that the (multiplicative) graph parameter \( f(G) = a^\#\text{loops}(G) \) where \( 1 \neq a \in \mathbb{F} \) (\( a \) can be 0) cannot be expressed as a GH function, even though its connection tensors \( T(f, k, n) \) all have symmetric rank 1 and \( f(K_0) = 1 \). To get the corresponding representation theorem for graphs with (multiple) loops, in the target graph \( H \) each loop \( e \) attached to a vertex \( i \) must have two weights: \( \beta_{ii} \) which is used when a nonloop edge of \( G \) is mapped onto \( e \), and the other, say \( \gamma_i \), when a loop of \( G \) is mapped onto \( e \). In this extended model we have the following:

- The main expressibility results Theorems 3.2, 3.3 and 3.4 remain true with the proof from Section 5 carrying over to this model with slight adjustments.
- The GH inexpressibility results from Sections 4 and 6 remain true as the provided proofs involve only simple loopless graphs. (For \#\text{VERTEX-DISJOINT-CYCLE-COVER} (\( \text{vdcc} \)), a loop at a vertex is considered a cycle cover of that vertex; this is consistent with the definition in Holant problems.)
- The results from Section 6.3 on bounded degree graphs remain true in the sense that the inexpressibility results hold if we allow \( \gamma_i \) to be arbitrary (again, since only simple loopless graphs
were used in the proof), while the expressibility holds even with the stronger requirement \( \gamma_i = \beta_i \).

Analogously, a GH expressibility criterion can be stated and proved within the framework of directed GH with minor adjustments, too. We note that generalizations of results in [19] were given in [28] to a more general model which captures directed graphs, hypergraphs, etc. We expect that it is possible to generalize the GH expressibility criterion in this paper for arbitrary fields to this more general model in a similar way as done in [28].

8 Appendix: Some Basic Concepts and Results

8.1 Multilinear algebra

We prove some statements about tensors. We assume that the reader is familiar with the definition of a multilinear function, tensor product, and dual space. It is good to start with coordinate-free definitions because it allows a succinct notation. But we will mostly use coordinates. The results are concrete, and they can be understood without too much formalism.

Unless stated otherwise, we do not impose a particular order on the rows and columns of matrices, or coordinates of tensors. The vector spaces may be infinite dimensional; and this infinite dimensionality is a main technical point that causes some complications.

The tensor product of vector spaces \( V_1, \ldots, V_n \) over \( \mathbb{F} \) is denoted by \( V_1 \otimes \cdots \otimes V_n \) or \( \otimes_{i=1}^n V_i \). Elements of \( \otimes_{i=1}^n V_i \) are called order-\( n \) tensors. When \( V_i = V \) for \( 1 \leq i \leq n \), we denote the tensor product by \( V^\otimes n \). (By convention \( V^\otimes 0 = \mathbb{F} \), and \( v^\otimes 0 = 1 \in \mathbb{F} \).) Define a group action by \( S_n \) on \( V^\otimes n \) induced by \( \sigma(\otimes_{i=1}^n v_i) = \otimes_{i=1}^n v_{\sigma(i)} \). Recall that \( V^\otimes n \) consists of finite linear combinations of such terms. We call a tensor \( A \in V^\otimes n \) symmetric if \( \sigma(A) = A \) for all \( \sigma \in S_n \), and denote by \( \text{Sym}^n(V) \) the set of symmetric tensors in \( V^\otimes n \). As \( \mathbb{F} \) may have finite characteristic \( p \), the usual symmetrizing operator from \( V^\otimes n \) to \( \text{Sym}^n(V) \), which requires division by \( n! \), is in general not defined.

Multilinear functions on \( \otimes_{i=1}^n V_i \) can be naturally identified with the dual space \( (\otimes_{i=1}^n V_i)^* \) of linear functions on \( \otimes_{i=1}^n V_i \), induced by \( f \mapsto f' \), satisfying \( f'(\otimes_{i=1}^n v_i) = f(v_1, \ldots, v_n) \). Moreover, \( \otimes_{i=1}^n V_i^* \) canonically embeds into \( (\otimes_{i=1}^n V_i)^* \) via \( (\otimes_{i=1}^n f_i)(\otimes_{i=1}^n v_i) = \prod_{i=1}^n f_i(v_i) \). A special case is that \( (V^*)^\otimes n \) embeds into \( (V^\otimes n)^* \). If all \( V_i \)'s are finite dimensional then this embedding is an isomorphism. However, if \( V_i \) are infinite dimensional, this embedding is not surjective. To see this, consider \( V^\otimes 2 \) where \( V \) is the linear span of \( \{e_i \mid i \in \mathbb{N}\} \). Let \( f \in (V^\otimes 2)^* \) be such that \( f(e_i \otimes e_j) = \delta_{ij} \), which is 1 if \( i = j \) and 0 otherwise. Then there is no tensor \( T \in (V^*)^\otimes 2 \) that embeds as \( f \). Indeed, any \( T \in (V^*)^\otimes 2 \) is, by definition, a finite sum \( T = \sum_{1 \leq k < n} c_k f_k \otimes g_k \). If \( T \) were to embed as \( f \), then consider the \( n \times n \) matrix where the \((i,j)\) entry is \( f(e_i \otimes e_j) \), which is the identity matrix \( I_n \) of rank \( n \). However \( T(e_i \otimes e_j) = \sum_{1 \leq k < n} c_k f_k(e_i) \cdot g_k(e_j) \), and so the matrix for the embedded \( T \) has rank \( < n \), being a sum of \( n - 1 \) matrices of rank \( \leq 1 \).

Let \( A_i : V_i \rightarrow U_i \) \((1 \leq i \leq n)\) be linear maps of vector spaces. They induce a homomorphism \( (\otimes_{i=1}^n V_i)^* \rightarrow (\otimes_{i=1}^n U_i)^* \) via \( f \mapsto g \), satisfying \( g(\otimes_{i=1}^n v_i) = f(\otimes_{i=1}^n A_i v_i) \).

If \( V_i \) are vector subspaces of \( U_i \), then \( \otimes_{i=1}^n U_i \) canonically embeds in \( \otimes_{i=1}^n V_i \). In particular, if \( V \subseteq U \), then \( V^\otimes n \) and \( \text{Sym}^n(V) \) canonically embed in \( U^\otimes n \) and \( \text{Sym}^n(U) \) respectively. Under this embedding \( \text{Sym}^n(V) = \text{Sym}^n(U) \cap V^\otimes n \). We will also denote the space of symmetric \( n \)-fold multilinear functions on \( V \) by \( \text{Sym}((V^\otimes n)^*) \), i.e., the functions from \( (V^\otimes n)^* \) that are symmetric. We have \( (V^*)^\otimes n \cap \text{Sym}((V^\otimes n)^*) = \text{Sym}^n(V^*) \).

In this paper, we will be interested in vector spaces of the form \( V = \bigoplus_{i \in I} F_i \), or just \( I \times F \),
where $\mathcal{I}$ is an (index) set and each $\mathbb{F}_i$, $i \in \mathcal{I}$, is a copy of $\mathbb{F}$ indexed by $i$. In this case $V$ has a basis $\{e_i \mid i \in \mathcal{I}\}$, and a vector $v \in V$ has finitely many nonzeros in this basis. Note that for infinite $\mathcal{I}$ this is a proper subset of $\mathbb{F}^\mathcal{I}$, and in particular $\{e_i \mid i \in \mathcal{I}\}$ is not a basis* for $\mathbb{F}^\mathcal{I}$. For $V = \bigoplus_\mathcal{I} \mathbb{F}$, the dual space $V^*$ can be identified with $\mathbb{F}^\mathcal{I}$ via $f \mapsto (f(e_i))_{i \in \mathcal{I}}$. For $V = \bigoplus_\mathcal{I} \mathbb{F}$, we have $V^{\otimes n} = \bigoplus_\mathcal{I} \mathbb{F}$, and $(V^{\otimes n})^*$ can be identified with $\mathbb{F}^{\mathcal{I}^n}$, the $n$-dimensional arrays. We can view $\text{Sym}(\mathbb{F}^{\mathcal{I}^n}) = \text{Sym}((V^{\otimes n})^*)$ as symmetric arrays, i.e., arrays in $\mathbb{F}^{\mathcal{I}^n}$ that are invariant under permutations from $S_n$, with respect to the basis $\{e_i \mid i \in \mathcal{I}\}$ of $V = \bigotimes_{i \in \mathcal{I}} \mathbb{F}$.

Any $A \in \bigotimes_{j=1}^n V_j$, where $n \geq 1$, can be expressed as a finite sum

$$A = \sum_{i=1}^r v_{i1} \otimes \cdots \otimes v_{in}, \quad v_{ij} \in V_j.$$

The least $r \geq 0$ for which $A$ has such an expression is called the rank of $A$, denoted by rank($A$). $A = 0$ iff rank($A$) = 0. If $r = \text{rank}(A) > 0$ then in any such expression of $A$ of $r$ terms all vectors $v_{ij} \neq 0$. When $n = 0$, $\bigotimes_{j=1}^n V_j$ is $\mathbb{F}$, and we define rank($A$) = 1 for $A \neq 0$ and rank($A$) = 0 for $A = 0$. Similarly, for $A \in \text{Sym}^n(V)$ we define the symmetric rank of $A$ to be the least $r \geq 0$ for which $A$ can be expressed as

$$A = \sum_{i=1}^r \lambda_i v_i^{\otimes n}, \quad \lambda_i \in \mathbb{F}, v_i \in V;$$

and is denoted by rk$_{\mathcal{S}}$(A). If there is no such decomposition we define rk$_{\mathcal{S}}$(A) = $\infty$. If rk$_{\mathcal{S}}$(A) < $\infty$ then in any such expression of $A$ as a sum of rk$_{\mathcal{S}}$(A) terms all $\lambda_i \neq 0$, all $v_i \neq 0$ and are pairwise linearly independent. We show in Lemma 8.6 that for infinite $\mathbb{F}$, rk$_{\mathcal{S}}$(A) < $\infty$ for all $A \in \text{Sym}^n(V)$.

We also need to refer to the rank of functions in $(\bigotimes_{i=1}^n V_i)^*$. As mentioned before $\bigotimes_{i=1}^n V_i^*$ is embedded as a subspace of $(\bigotimes_{i=1}^n V_i)^*$. For a function $F \in (\bigotimes_{i=1}^n V_i)^*$, where $n \geq 1$, we define the rank of the function $F$ to be $\infty$ if $F \notin \bigotimes_{i=1}^n V_i^*$, and if $F \in \bigotimes_{i=1}^n V_i^*$, the rank of $F$ is the least $r$ for which $F$ can be written as

$$F = \sum_{i=1}^r f_{i1} \otimes \cdots \otimes f_{in}, \quad f_{ij} \in V_j^*.$$  

When $n = 0$, $(\bigotimes_{j=1}^n V_j)^*$ is $(\mathbb{F})^* \cong \mathbb{F}$, and we define rank($F$) = 1 for $F \neq 0$ and rank($F$) = 0 for $F = 0$. The symmetric rank rk$_{\mathcal{S}}$(F) of $F \in \text{Sym}((V^{\otimes n})^*)$ is similarly defined. It is $\infty$ if $F \notin \text{Sym}^n(V^*)$. For $F \in \text{Sym}^n(V^*)$, we define rk$_{\mathcal{S}}$(F) to be the least $r$ such that

$$F = \sum_{i=1}^r \lambda_i f_i^{\otimes n}, \quad \lambda_i \in \mathbb{F}, \quad f_i \in V^*;$$

if such an expression exists; rk$_{\mathcal{S}}$(F) = $\infty$ otherwise. By the same Lemma 8.6 for infinite $\mathbb{F}$, we have rk$_{\mathcal{S}}$(F) < $\infty$ for all $F \in \text{Sym}^n(V^*)$.

Basically, the rank of a multilinear function is just an extension of the tensor rank from $\bigotimes_{i=1}^n V_i^*$ to $(\bigotimes_{i=1}^n V_i)^*$. Similarly the symmetric rank is the extension from $\text{Sym}^n(V^*)$ to $\text{Sym}((V^{\otimes n})^*)$.

*Of course every vector space has a basis; however this requires Zorn’s Lemma so the proof is nonconstructive. In this paper our results are constructive usually working with an explicitly given basis.
Clearly for all symmetric $A$, rank$(A) \leq \text{rk}_S(A)$. Both rank and $\text{rk}_S$ are unchanged when moving from $\bigotimes V_i$ to $\bigotimes U_i$, if $V_i \subseteq U_i$.

The following Lemmas 8.1-8.5 are restatements of Lemmas 2.1-2.5, respectively, but with proofs included.

**Lemma 8.1.** The vectors $x_1, \ldots, x_r \in F^I$ are linearly independent iff in the $r \times I$ matrix formed by $x_1, \ldots, x_r$ as rows there exists a nonzero $r \times r$ minor.

*Proof.* $\Leftarrow$ is obvious, so let us prove $\Rightarrow$. Let $R \subseteq [r]$ be a maximal subset satisfying the property that for some finite subset $C \subseteq I$ the set of vectors $\{x_i | C : i \in R\}$ is linearly independent, where $x_i | C$ is the restriction of $x_i$ to $C$. Suppose linear independence is achieved by $C$ for $R$. Then it also holds for any $C' \supseteq C$.

If $R \neq [r]$, let $j \in [r] \setminus R$, and consider $R^+ = R \cup \{j\}$. $\{x_i | C : i \in R^+\}$ is linearly dependent. Hence a unique linear combination holds for some $c_i \in F (i \in R)$,

$$x_j | C = \sum_{i \in R} c_i x_i | C . \quad (8.1)$$

For any $k \notin C$, $\{x_i | C \cup \{k\} : i \in R^+\}$ is also linearly dependent, and we have $x_j | C \cup \{k\} = \sum_{i \in R} c_i' x_i | C \cup \{k\}$ for some $c_i' \in F$. Compared to (8.1), $c_i' = c_i$ for all $i \in R$. Hence $x_j = \sum_{i \in R} c_i x_i$, a contradiction to $\{x_1, \ldots, x_r\}$ being linearly independent. So $R = [r]$. There exists a nonzero $r \times r$ minor in the $R \times C$ submatrix. \hfill \Box

For $x = (x_i)_{i \in I} \in F^I$ and $h = (h_i)_{i \in I} \in \bigoplus_I F$ (in a direct sum, only finitely many $h_i$ are zero), we denote their dot product by $x(h) = \sum_{i \in I} x_i h_i \in F$. (In general the dot product for $x, y \in F^I$ is not defined.)

**Lemma 8.2.** Let $x_1, \ldots, x_r \in F^I$ be linearly independent. Then there exist $h_1, \ldots, h_r \in \bigoplus_I F$ dual to $x_1, \ldots, x_r$, i.e., $x_i(h_j) = \delta_{ij}$, $1 \leq i, j \leq r$.

*Proof.* By Lemma 8.1, there exist $r$ distinct indices $k_j \in I$, $1 \leq j \leq r$ such that the matrix $A = (a_{ij})_{i,j=1}^r = ((x_i)_{k_j})_{i,j=1}^r$ is invertible, and let $B = (b_{ij}) = A^{-1}$. Taking $h_i = \sum_{j=1}^r b_{ji} e_{k_j} \in \bigoplus_I F$, $1 \leq i \leq r$, we see that the equality $AB = I_r$ directly translates into the desired result. \hfill \Box

**Lemma 8.3.** Let $x_1, \ldots, x_r \in F^I$. Consider the linear map $\Phi : \bigoplus_I F \to F^r$, $h \mapsto (x_1(h), \ldots, x_r(h))$. Then $\text{dim}(\bigoplus_I F / \ker \Phi) = \text{dim} \text{span}\{x_i\}_{i=1}^r$.

*Proof.* By the First Isomorphism Theorem for vector spaces $\bigoplus_I F / \ker \Phi \cong \text{im} \Phi$. So it suffices to prove $\text{dim im} \Phi = \text{dim span}\{x_i\}_{i=1}^r$. Clearly it suffices to prove the case when $x_1, \ldots, x_r$ are linearly independent, and that follows directly from Lemma 8.2. \hfill \Box

**Lemma 8.4.** Let $r \geq 0$, and let $x_1, \ldots, x_r \in F^I$ be $r$ linearly independent vectors and $a_1, \ldots, a_r \in F \setminus \{0\}$. Then for any integer $n \geq 2$, the symmetric tensor

$$A = \sum_{i=1}^r a_i x_i \otimes^n \in \text{Sym}^n(F^I) \quad (8.2)$$

has $\text{rk}_S(A) = r$. For $n \geq 3$, any expression of $A$ as $\sum_{i=1}^r b_i y_i \otimes^n$ is a permutation of the sum in (8.2).
Proof. When \( r = 0 \), the statement is trivially true so we assume \( r \geq 1 \). Let \( n \geq 2 \) and \( \text{rk}_S(A) = s \). Clearly \( s \leq r \). By being of symmetric rank \( s \), there exist \( y_1, \ldots, y_s \in F^T \) and \( b_1, \ldots, b_s \in F \setminus \{0\} \) such that

\[
\sum_{i=1}^{r} a_ix_i^{\otimes n} = A = \sum_{j=1}^{s} b_jy_j^{\otimes n}. \tag{8.3}
\]

By Lemma 8.2, there exist \( h_1, \ldots, h_r \) dual to \( x_1, \ldots, x_r \). For any \( 1 \leq i \leq r \), applying \( h_i^{\otimes (n-1)} \) to the sum, we get \( a_ix_i \) as a linear combination of \( y_1, \ldots, y_s \). Hence \( s \geq r \) as \( x_1, \ldots, x_r \) are linearly independent. So \( s = r \), and \( y_1, \ldots, y_s \) are linearly independent.

Next, let \( n \geq 3 \) and consider (8.3) again, where \( s = r \). Since \( \text{rk}_S(A) = r \), all \( b_j \neq 0 \). Applying \( h_i \), we get

\[
a_ix_i^{\otimes (n-1)} = B = \sum_{j=1}^{r} b_jy_j(h_i)y_j^{\otimes (n-1)}. \tag{8.4}
\]

From the LHS, \( \text{rk}_S(B) = 1 \). By what has just been proved, \( \text{rk}_S(B) \) is the number of terms with nonzero coefficients on the RHS. Hence for any \( i \), there is exactly one \( j \) such that \( y_j(h_i) \neq 0 \). Applying \( h_i^{\otimes (n-2)} \) to (8.4), we get \( a_ix_i = b'_jy_j \), where \( b'_j = b_j(y_j(h_i))^{-1} \neq 0 \). Since \( x_1, \ldots, x_r \) are linearly independent, the map \( i \mapsto j \) is a permutation. From \( a_ix_i = b'_jy_j \) we get \( a_i = b'_jy_j(h_i) = b_j(y_j(h_i))^n \). It follows that \( y_j = (a_i/b'_j)x_i = y_j(h_i)x_i \). Therefore \( b_jy_j^{\otimes n} = b_jy_j^{\otimes n}x_i^{\otimes n} = a_ix_i^{\otimes n} \). Thus the expressions on LHS and RHS of (8.3) are the same up to a permutation of the terms.

**Lemma 8.5.** Let \( r \geq 0 \), and let \( x_1, \ldots, x_r \in F^T \) be \( r \) nonzero pairwise linearly independent vectors. Then for any nonnegative integer \( n \geq r - 1 \), the rank-1 symmetric tensors

\[
x_1^{\otimes n}, \ldots, x_r^{\otimes n} \in \text{Sym}^n(F^T)
\]

are linearly independent.

**Proof.** The case \( r = 0 \) is vacuously true. It is also trivially true for \( r = 1 \), since \( x_1^{\otimes n} \) is nonzero. Assume \( r \geq 2 \). By pairwise linear independence, for every \( 1 \leq i, j \leq r, i \neq j \), from Lemma 8.2 there exists \( h_{ij} \) such that \( x_i(h_{ij}) = 1, x_j(h_{ij}) = 0 \). Suppose \( \sum_{i=1}^{r} \lambda_i x_i^{\otimes (n-1)} = 0 \) where \( \lambda_i \in F, 1 \leq i \leq r \). Applying \( \otimes_{1 \leq j \leq r, j \neq i} h_{ij} \), we get \( \lambda_i x_i^{\otimes (n-(r-1))} = 0 \) for \( 1 \leq i \leq r \), and thus \( \lambda_i = 0 \) since \( n \geq r - 1 \) and therefore \( x_i^{\otimes (n-(r-1))} \) is nonzero. Hence \( x_1^{\otimes n}, \ldots, x_r^{\otimes n} \) are linearly independent.

**Remark:** For \( r \geq 2 \), the nonzero hypothesis is subsumed by pairwise linear independence.

### 8.2 Finite symmetric tensor rank

The proof of the following lemma is essentially the same as Lemma 4.2 in [15]; the only modification needed is to avoid a symmetrization step, which could result in a division by 0 in a field of finite characteristic.

**Lemma 8.6.** If \( F \) is a field of cardinality \(|F| > n\), a fortiori if \( F \) is infinite, and \( V \) is a vector space over \( F \), then every symmetric tensor \( A \in \text{Sym}^n(V) \) has a finite symmetric tensor rank \( \text{rk}_S(A) < \infty \). Moreover, when \( \dim V < \infty \), we have \( \text{rk}_S(A) \leq \left( \frac{\dim V + n - 1}{n} \right) \).
Proof. By definition, every \( A \in \text{Sym}^n(V) \subseteq V^\otimes n \) is a finite sum \( A = \sum_{i=1}^m v_{i1} \otimes \cdots \otimes v_{im} \). Let \( V' = \text{span}\{v_{ij} \mid i \in [m], j \in [n]\} \) be a finite dimensional subspace of \( V \). As \( A \in \text{Sym}^n(V') \), we can assume \( V \) is finite dimensional, with no change in \( \text{rk}_F(A) \); so we let \( V = \mathbb{F}^N \), for some \( N \).

Let \( T = \text{span}\{x^\otimes n \mid x \in V\} \subseteq \text{Sym}^n(V) \). Our claim is that equality holds. For every entry of \( x^\otimes n \), which is a product of coordinate entries of \( x \), we can classify it by how many factors are the \( j \)-th coordinate of \( x \), for \( j \in [N] \). There are \( \binom{n+N-1}{N-1} = \binom{n+n-1}{n} \) coordinates which can be indexed by tuples \((i_1, \ldots, i_N)\) where \( i_1, \ldots, i_N \geq 0 \) and \( i_1 + \cdots + i_N = n \), such that every entry of every \( t \in T \) is equal to its entry at one of these coordinates. We define a compression operator \( C \) which selects only those \( \binom{n+n-1}{n} \) coordinates, and define

\[
S = \text{span}\{C(x^\otimes n) \mid x \in V\} = \{C(t) \mid t \in T\}.
\]

The compression operator \( C \) is also applicable to \( \text{Sym}^n(V) \). Indeed, by definition as a symmetric array in \( \mathbb{F}^N \), any \( A \in \text{Sym}^n(V) \) is invariant under any permutation of \( n \). This means that for any \((k_1, \ldots, k_n)\), where \( k_1, \ldots, k_n \in [N] \), and any permutation \( \pi \in S_n \), if \((e_1^\pi, \ldots, e_n^\pi)\) are the dual basis to the canonical basis of \( V \), then \((e_{i_1}^\pi \otimes \cdots \otimes e_{i_n}^\pi)(A) = (e_{k_{\pi(i)}}^\pi \otimes \cdots \otimes e_{k_{\pi(n)}}^\pi)(A)\). This invariance can be characterized by the tuple \((i_1, \ldots, i_N)\), where \( i_j \) is the number \( j \in [N] \) among \((k_1, \ldots, k_n)\). Thus \( C \) is applicable to \( \text{Sym}^n(V) \), and we denote the result \( C(\text{Sym}^n(V)) = \{C(v) \mid v \in \text{Sym}^n(V)\} \subseteq \mathbb{F}^{(N+n-1)} \). As \( T \subseteq \text{Sym}^n(V) \), we have \( S \subseteq C(\text{Sym}^n(V)) \).

Next we prove that \( S = \mathbb{F}^{(N+n-1)} \). Then it follows that \( S = C(\text{Sym}^n(V)) \), from which it clearly follows that \( T = \text{Sym}^n(V) \) since \( C \) simply removes repeated entries.

Suppose otherwise, then \( \dim S < \binom{n+n-1}{n} \). There exists a nonzero vector in \( \mathbb{F}^{(N+n-1)} \) such that it has a zero dot product with all \( S \). This means there exists a nonzero tuple \((a_{1(i_1, \ldots, i_N)}) \in \mathbb{F}^{(N+n-1)}\) indexed by \( N \)-tuples of nonnegative integers that sum to \( n \), such that \( \sum_{i_1, \ldots, i_N} a_{1(i_1, \ldots, i_N)} x_1^{i_1} \cdots x_N^{i_N} = 0 \), for all \( x_1, \ldots, x_N \in \mathbb{F} \).

As a polynomial in \( x_N \) it has degree at most \( n \), and yet it vanishes at \( |\mathbb{F}| > n \) points. So for any fixed \( 0 \leq i_N \leq n \), \( \sum_{i_1, \ldots, i_{N-1}} a_{(i_1, \ldots, i_{N-1}, i_N)} x_1^{i_1} \cdots x_{N-1}^{i_{N-1}} = 0 \), for all \( x_1, \ldots, x_{N-1} \in \mathbb{F} \), which can be viewed as a polynomial in \( x_{N-1} \) of degree at most \( n - i_N \leq n \). Iterate \( N \) steps we reach a contradiction that the tuple \((a_{1(i_1, \ldots, i_N)})\) is entirely zero.

\( \square \)

### 8.3 Subalgebras of \( \mathbb{F}^m \)

We give a proof of Lemma 5.11, restated below.

**Lemma 8.7.** All subalgebras of \( \mathbb{F}^m \), where \( m \geq 0 \), are of the following form: For some partition \([m] = \bigsqcup_{i=1}^s I_i\), where \( s \geq 0 \), and \( I_i \neq \emptyset \) for \( i \in [s] \), the subalgebra has equal values on each \( I_i \),

\[
\mathbb{F}^{(I_1, \ldots, I_s)} = \{(c_1, \ldots, c_m) \in \mathbb{F}^m : \forall i \in [s], \forall j, j' \in I_i, c_j = c_{j'}\}.
\]

**Proof.** When \( m = 0 \), the statements is obvious. Let \( m \geq 1 \) and \( S \subseteq \mathbb{F}^m \) be a subalgebra of \( \mathbb{F}^m \). In particular, the multiplicative identity is the \( m \)-tuple \((1, \ldots, 1) \in S \). We call \( i, j \in [m] \) equivalent if \( x_i = x_j \) for any \( x = (x_1, \ldots, x_m) \in S \). This is clearly an equivalence relation so it partitions \([m]\) into (nonempty) equivalence classes \( I_1, \ldots, I_s \) so that \([m] = \bigsqcup_{i=1}^s I_i \). As \([m] \neq \emptyset \) we have \( s \geq 1 \). We claim that \( S = \mathbb{F}^{(I_1, \ldots, I_s)} \). Clearly, \( S \subseteq \mathbb{F}^{(I_1, \ldots, I_s)} \). We prove the reverse inclusion. For \( s = 1 \) this is clearly true since the \( m \)-tuple \((1, \ldots, 1) \in S \) and \( S \) is closed under scalar multiplication.
Now we let $s \geq 2$. By renaming and omitting repeated coordinates it is sufficient to prove the case when $m = s$ and $I_i = \{i\}$. Let $S' = \{(c_2, \ldots, c_s) \mid \exists c_1 \in F, (c_1, c_2, \ldots, c_s) \in S\}$ be the projection of $S$ to $F^{s-1}$. Clearly $S'$ is a subalgebra of $F^{s-1}$, and by induction $S' = F^{s-1}$. Thus for some $b_1, \ldots, b_{s-1} \in F$, all $s - 1$ row vectors of the following $(s - 1) \times s$ matrix $B$ belong to $S$,

$$B = \begin{bmatrix} b_1 & 1 & 0 & \cdots & 0 \\ b_2 & 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ b_{s-1} & 0 & 0 & \cdots & 1 \end{bmatrix}. \tag{8.5}$$

If all $b_i = 0$, we let $v = (1,1,\ldots,1) \in S$. Otherwise we may assume $b_1 \neq 0$. By the definition of $I_1$ and $I_2$ and by the closure of $S$ under scalar product and possibly adding $(1,1,\ldots,1)$, for some $c_1 \neq 1$ and for some $c_3, \ldots, c_s \in F$, we have $v' = (c_1, c_3, \ldots, c_s) \in S$. Then multiplying $v'$ with the first row in (8.5) we get $v = (b_1c_1, 1,0,\ldots,0) \in S$. In either case, we obtain a matrix $A$ of rank $s$ by appending $v$ as the last row to $B$. Thus for all row vectors $d \in F^s$ the linear system $xA = d$ has a solution $x \in F^s$. This shows that $d \in S$. □
