Extended Self-Similarity in Turbulent Systems: an Analytically Soluble Example

Daniel Sege, Victor L'vov and Itamar Procaccia

Department of Chemical Physics, The Weizmann Institute of Science, Rehovot 76100, Israel

In turbulent flows the \( n \)'th order structure functions \( S_n(R) \) scale like \( R^{\zeta_n} \) when \( R \) is in the "inertial range". Extended Self-Similarity refers to the substantial increase in the range of power law behaviour of \( S_n(R) \) when they are plotted as a function of \( S_2(R) \) or \( S_3(R) \). In this Letter we demonstrate this phenomenon analytically in the context of the "multiscaling" turbulent advection of a passive scalar. This model gives rise to a series of differential equations for the structure functions \( S_n(R) \) which can be solved and shown to exhibit extended self similarity. The phenomenon is understood by comparing the equations for \( S_n(R) \) to those for \( S_n(S_2) \).

PACS numbers 47.27.Gs, 47.27.Jv, 05.40.+j

The fundamental theory of turbulence concerns itself with the universality of the small scale structure of turbulent flows and their characterization by universal scaling laws [1]. Since the days of Kolmogorov [2] one expects the structure functions \( S_n(R) \) to scale with \( R \) long as \( R \) is in the inertial range

\[
S_n(R) \sim R^{\zeta_n}, \quad \text{for } \eta \ll R \ll L . \tag{1}
\]

Here \( \eta \) and \( L \) are the viscous and outer lengths respectively. For a given turbulent field \( u(r,t) \) the \( n \)'th order structure function is defined as

\[
S_n(R) = \langle [u(r + R, t) - u(r, t)]^n \rangle .
\]

where the angular brackets \( \langle \ldots \rangle \) denote an average over \( r \) and \( t \). Komogorov's 1941 picture of turbulence (K41) predicted that the exponents of the structure functions of the velocity field satisfy \( \zeta_n = n/3 \). Further research along the same lines suggested that the structure functions of passive scalars densities also have the same exponents [3]. On the other hand experiments [4,5] have indicated deviations from this scaling and even the possibility of multiscaling, i.e. a non-linear dependence of \( \zeta_n \) on \( n \). These findings raise fundamental questions as to our understanding of the universality of the small scale structure of turbulence.

Unfortunately, the experimental measurement of the scaling exponents in turbulent flows is hampered by the fact that the range of scales that exhibit scaling behaviour is rather small for Reynolds numbers \( Re \) accessible to date. Even though the viscous scale \( \eta \) decreases like \( Re^{-3/4} \), the scaling behaviour [4] is expected to set in only at about \( 10^5 \eta \), and cease at about \( L/100 \). Thus even at \( Re \sim 10^7 \) the inertial range is not broad enough to allow accurate measurements of \( \zeta_n \), particularly for larger values of \( n \).

A partial resolution of these difficulties has been recently offered [6] by changing the way that the experimental data is presented. Instead of plotting log-log plots of \( S_n(R) \) vs. \( R \), it was argued that plotting log-log plots of \( S_n(R) \) vs. \( S_2(R) \) or \( S_3(R) \) reveals much longer scaling ranges that can be used to fit accurate exponents. This method was dubbed Extended Self Similiarity. While the effectiveness of this method has been demonstrated [7], the reason for its success remains unclear. Therefore its reliability is not guaranteed. The aim of this Letter is to address this method theoretically for Kraichan's model of a passive scalar advected by a very rapidly varying velocity field [8]. In this model multiscaling is known to occur [9], and we have sufficient analytic understanding of the mechanism of (mult)iscaling to assess why Extended Self Similiarity could hold. One should stress that in the case of normal scaling Extended Self Similiarity can be rationalized rather straightforwardly [4]. To our knowledge no analytic derivation of this effect is available in a case exhibiting multiscaling.

In this model the equation for the passive scalar concentration \( T(x) \) is given by

\[
\frac{\partial T}{\partial t} + (u \cdot \nabla)T = \kappa \nabla^2 T , \tag{2}
\]

where the velocity field \( u \) is taken as Gaussian random and with a \( \delta \)-function correlation in time. The structure functions \( S_{2n}(R) \) are know to obey differential equations [10]

\[
R^{1-d} \frac{\partial}{\partial R} R^{d-1} h(R) \frac{\partial}{\partial R} S_{2n}(R) = J_{2n}(R) . \tag{3}
\]

Here \( h(R) = H(R/L)^{\zeta_h} \) for \( R < L \) where \( H \) is a dimensional constant and \( L \) is some characteristic outer scale of the driving velocity field. The Scaling exponent \( \zeta_h \) is a chosen parameter in this model, taking any desired value in the interval \( (0,2) \). The function \( J_{2n}(R) \) is known exactly for \( R \) in the inertial range [2], but for our purposes we need to know it also in the near viscous range. A form that is appropriate in both ranges has been suggested by Kraichnan [11]:

\[
J_{2n}(R) = 2n \kappa \frac{S_{2n}(R)}{S_2(R)} [\nabla^2 S_2(R) - \nabla^2 S_2(0)] . \tag{4}
\]

This form has been recently supported by numerical simulations [12]. In the inertial range the last two equations
have a multiscaling solution for $S_{2n}(R)$ with the

$$\zeta_{2n} = \frac{1}{4} \left[ \sqrt{(3 - \zeta_2)^2 + 12n\zeta_2 + \zeta_2 - 3} \right].$$

(5)

Our first step in studying the issue of Extended Self-Similarity using Eqs. (3) is to non-dimensionalize them. Rescale lengths by $r_d = \mathcal{L}/(\kappa/H)^{1/\zeta_2}$ and the scalar density by $\Theta = r_d/\epsilon/\kappa$. The dimensionless functions, $D_{2n}(y)$ are:

$$D_{2n}(y) = S_{2n}(yr_d)/\Theta^{2n}, \quad y = R/r_d.$$  

(6)

They satisfy the equations

$$\frac{d^2D_{2n}}{dy^2} + \frac{2 + \zeta_0}{y} \frac{dD_{2n}}{dy} = \frac{2nD_{2n}}{D_{2y^{2n}}} \left[ 1 - \frac{d^2D_{2n}}{dy^2} \right].$$

(7)

The success of extended self similarity for this model can be assessed from Fig.1 which compares plots of $\zeta_{2n}$ vs. $y$ with plots of $D_{2n}$ vs. $D_2$. The data is based on the numerical solution of Eq.(6) using the IMSL/IDL’s Adams-Gear ODE-solver. The efficacy of Extended Self Similarity speaks for itself.

Next we exhibit the phenomenon analytically by finding the first order dissipative correction to the inertial range scaling of the structure functions. In the inertial range the exponent of $D_{2n}(y)$ is $\zeta_2 = 2 - \zeta_0$. We can find the first correction to the power law, going into the dissipation range, by writing $D_{2n}(y) = 2y^{\zeta_2}/3\zeta_2 + \epsilon(y)$. We then find the following ODE for $\epsilon(y)$:

$$\frac{d^2\epsilon}{dy^2} + \frac{2 + \zeta_0}{y} \frac{d\epsilon}{dy} + \frac{4(1 - \zeta_0)}{3y^{2\zeta_0}} = 0.$$  

(8)

There are two possibilities for the leading order solution of this equation. If all the terms are of the same order the solution is $\epsilon_1 = -2y^{2-2\zeta_0}/3(1 + \zeta_2)$. If the first two terms are larger we have $\epsilon_2 = B_2 + \epsilon_1$, where now $\epsilon_1$ appears as the next order correction after a constant $B_2$. One can see that the dominant solution for small $\zeta_0$ is $\epsilon_1$, with a transition to $\epsilon_2$ at $\zeta_0 = 1$. Thus the near-inertial solution for $D_2$ is

$$D_2(y) = \frac{2y^{\zeta_2}}{3\zeta_2} \left( 1 - \frac{\zeta_0 y^{\zeta_2 - 2}}{1 + \zeta_2} \right) \text{ for } \zeta_0 < 1,$$

(9)

$$D_2(y) = \frac{2y^{\zeta_2}}{3\zeta_2} \left( 1 + \frac{C_2 y^{\zeta_2}}{\zeta_2} \right) \text{ for } \zeta_0 > 1,$$

(10)

where $C_2$ is a constant. Note that for the case $\zeta_0 = 2/3$ the ODE for $D_2(y)$ can be solved exactly in terms of elementary operations and the results are consistent with this solution.

Next we repeat this procedure for $D_{2n}(y)$. We substitute $D_{2n}(y) = A_{2n}y^{\zeta_{2n}}[1 + \xi(y)]$ in Eq.(6). For the case $\zeta_0 > 1$ we find

$$\frac{d^2\xi}{dy^2} + \frac{2 + \zeta_0}{y} \frac{d\xi}{dy} (2\zeta_{2n} + 4 - \zeta_2) + \frac{3nC_2\zeta_2}{y^{2(\zeta_2)}} = 0,$$

(11)

with a leading order scaling solution $\xi(y) = B_{2n}y^{-\zeta_2}$. The constant is found from Eq.(11) and the final result for $\zeta_0 < 1$ is

$$D_{2n}(y) = A_{2n}y^{\zeta_{2n}} \left[ 1 + \frac{3nC_2}{(2\zeta_{2n} + 3 - 2\zeta_2)y^{\zeta_2}} \right].$$

(12)

At this point we can assess the efficacy of Extended Self Similarity for the case $\zeta_0 > 1$. If all functions $D_{2n}$ were an exact power law in argument $D_2$ we would have

$$D_{2n}^{\text{RES}}(y) = \left[ \frac{2(\zeta_2 + C_2)}{3\zeta_2} \right]^{\zeta_{2n}/\zeta_2},$$

(13)

or in the same order

$$D_{2n}^{\text{RES}}(y) = A_{2n}y^{\zeta_{2n}} \left( 1 + \frac{\zeta_0 C_2}{\zeta_2 y^{\zeta_2}} \right).$$

(14)

The ratio $r_1$ between the coefficients of $y^{-\zeta_2}$ in Eqs. (12) and (14) measures the effectiveness of this presentation. Using Eq. (11) one finds

$$r_1 = \frac{3n\zeta_2}{\zeta_{2n}(2\zeta_{2n} - 3 - \zeta_2)} = \frac{nC_2}{2n\zeta_2 - \zeta_2}.$$  

(15)

If $r_1 = 1$ we would have perfect Extended Self Similarity; $r_1 = 0$ is what we would get if we just plotted $S_{2n}$ as a function of $r$. In Fig. 2(a) we can see a graph of $r_1$ as a function of $\zeta_2$ for $n = 2, 4$ and $n = 6$. We can see that $r_1$ is always in the interval $[0.2, 1]$: from Eq. (11) $\lim_{n \to \infty} r_1 = \frac{1}{4}$, and from Eqs. (3), (11) $\lim_{\zeta_0 \to 0} r_1 = 1$. The convergence to 1/2 is rather slow and not uniform in $\zeta_2$.

The main point of the Extended Self Similarity is that $S_2$ (which is a function of $R$) is a “better” variable than the distance $R$ itself when it comes to scaling behaviour. Thus, to complete our analysis we want to write the equations for $S_{2n}$ as ODE’s with respect to argument $S_2$ with the inertial range scaling plus a remainder term. Changing variables and writing the $S_{2n}$ as a function of $S_2$, we expect to find that the remainder term, evaluated in terms of the inertial range estimates, is smaller than when using $r$ as a variable. To this aim we introduce a new set of function $F_{2n}(x)$ of argument $x = D_2(y)$:

$$F_{2n}(x) \equiv D_{2n}(y), \quad x \equiv D_2(y).$$

(16)

Then Eqs. (6) gives for $F_{2n}(x)$ the following ODE

$$\frac{d^2F_{2n}}{dx^2} + \frac{2 + [f(x)]^{2-\zeta_2}}{x} \left[ \frac{dF_{2n}}{dx} - \frac{nF_{2n}(x)}{x} \right] \times \left[ \frac{d^2f}{dx^2} + \frac{4(1 - \zeta_0)}{f(x)} \frac{df}{dx} \right] = 0,$$

(17)

where $f(x)$ is the inverse function of $S_2(y)$: $f(x) = y$ if $x = S_2(y)$. Now let us introduce a third set of dimensionless structure functions, $G_{2n}(z)$ such that
\[ G_{2n}(x) \equiv D_{2n}(y), \quad x \equiv 2y^{\zeta_2/3\zeta_2}. \] (18)

Note that the functions \( F_{2n} \) and \( G_{2n} \) are identical in the inertial range, since one is a function of \( S_2 \) and the other is a function of its power law in the inertial range. Indeed, it will be seen below that they satisfy the same ODE in the inertial range with a power solution \( x^{\zeta_{2n}/\zeta_2} \). Using (6) one derives the following ODE for \( G_{2n}(x) \):

\[
\frac{d^2G_{2n}}{dx^2} + 3 \frac{1}{\zeta_2x} \left[ \frac{dG_{2n}}{dx} - \frac{nG_{2n}(x)}{g(x)} \right] + \frac{3ng_{2n}(x)}{g(x)x^{2/\zeta_2}} \left( (\zeta_2 - 1) \frac{dg}{dx} + \zeta_2 \frac{d^2g}{dx^2} \right) = 0
\] (19)

with the function \( g(x) \) satisfying \( g(x = D_2(y)) = D_2(y) \).

Consider first the \( \zeta_2 < 1 \) case, and use the near-inertial approximation for \( S_2(y) \), Eq. (10). Inverting this relation we find the relevant approximation for \( f \) in terms of \( x \), i.e.

\[
f(x) = \left( \frac{3\zeta_2}{2} \right)^{1/\zeta_2} \left( 1 - 2\zeta_2 \right) \left( \frac{2\zeta_2}{3\zeta_2} \right). \] (20)

Using this and introducing constants \( C_{2n}^0, S_{2n} = C_{2n}^0x^{\zeta_{2n}/\zeta_2} \) in the remainder term we find that the near-inertial version of Eq. (14) is

\[
\frac{d^2F_{2n}}{dx^2} + 3 \frac{1}{\zeta_2x} \left[ \frac{dF_{2n}}{dx} - \frac{nF_{2n}(x)}{x} \right] + \frac{2C_2C_0^0}{\zeta_2^3} \left( \zeta_2 - n\zeta_2 \right) x^{\zeta_{2n}/\zeta_2 - 3} = 0.
\] (21)

Doing the same to Eq. (15) we have

\[
\frac{d^2G_{2n}}{dx^2} + 3 \frac{1}{\zeta_2x} \left[ \frac{dG_{2n}}{dx} - \frac{nG_{2n}(x)}{x} \right] + \frac{2C_2C_0^0}{\zeta_2^3} n x^{\zeta_{2n}/\zeta_2 - 3} = 0.
\] (22)

Indeed, we see that the first lines of these equations, which are the inertial range contributions, are the same. Also the second lines are of the same order in \( y \) but the ratio \( r_2 \) between the coefficients in these lines (reminder terms) is

\[ r_2 = \frac{\zeta_2 - n\zeta_2}{n\zeta_2}. \] (23)

Since the Hölder inequalities imply that \( \zeta_{2n} \leq n\zeta_2 \), we have \( |r_2| \leq 1 \); this means that indeed the remainder term that “spoils” the inertial range scaling to first order is smaller in the new representation. One can see, by solving Eq. (17) in terms of the coefficient of the remainder term, using \( F_{2n}(x) \) to express \( D_{2n}(y) \) back again and comparing with Eq. (12), that one should have the relation

\[ r_2 = 1 - \frac{1}{r_1}. \] (24)

Now comparing Eqs. (15) and (23) one sees that this relation is true. Extended Self Similarity as represented by \( r_1 \) very near unity indeed translates into very small \( r_2 \), that is into a small remainder term. In Fig. 2(b) we can see \( r_2 \) as a function of \( \zeta_2 \) for \( n = 2, n = 4 \) and \( n = 6 \). As \( n \to \infty \) the ratio becomes poor, \( r_2 \to -1 \) but the convergence is slow as we can see from Fig. 2(b) and again not uniform in \( \zeta_2 \), since one can verify that \( \lim_{\zeta_2 \to 0} r_2 = 0 \).

The situation for \( \zeta_2 > 1 \) is much messier algebraically although just the same procedure can be followed in principle. We have already given in Eq. (10) the near-inertial form for \( D_2(y) \) for \( \zeta_2 > 1 \); we now substitute this and \( D_{2n}(y) = A_{2n}y^{\zeta_{2n} \left[ 1 + \xi(y) \right]} \) [considered as a definition of \( \xi(y) \)] into Eq. (4) to find the equation

\[
\frac{d^2\xi}{dy^2} + (2\zeta_2 + 4 - \zeta_2) \frac{d\xi}{dy} + n\zeta_2(1 + 2\zeta_2)(2 - \zeta_2) \left( \frac{y^{\zeta_2 - 4}}{(\zeta_2 + 1)} \right) = 0.
\] (25)

This equation has an obvious power law solution which leads to

\[
D_{2n}(y) = A_{2n}y^{\zeta_{2n} \left[ 1 + \frac{n\zeta_2(1 + 2\zeta_2)(2 - \zeta_2)}{(\zeta_2 + 1)(1 + 2\zeta_{2n})} \right] y^{\zeta_2 - 2}}.
\] (26)

(For \( \zeta_2 > 1 \), which gives

\[ r_1 = \frac{n\zeta_2(1 + 2\zeta_2)}{\zeta_{2n}(1 + 2\zeta_{2n})}. \] (27)

In Fig. 3 we can see \( r_1 \) as a function of \( \zeta_2 \) for \( n = 2, n = 4 \) and \( n = 6 \). For very large \( n \) we can see that

\[ \lim_{n \to \infty} r_1 = \frac{1 + 2\zeta_2}{6} \in [\frac{1}{2}, \frac{5}{6}] \], (28)

but the convergence is slow as we can see from Fig. 3 and again not uniform in \( \zeta_2 \), since one can verify that \( \lim_{\zeta_2 \to 0} r_1 = 1 \). Again one can verify that the efficacy of ESS is reflected in a smaller remainder term in the ODE for \( S_{2n} \) using \( S_2 \) as a variable, as expressed by a ratio \( r_2 \) for which here too \( r_2 = 1 - r_1^{-1} \).

The success of the method in this case cannot be glibly extended to any turbulent system. We see from the analysis that the improvement in the scaling behaviour of \( S_n \) when presented as a function of \( S_2 \) is not a fundament result but a statement on the similar behaviour of the structure functions going into the dissipation range. This is measured by the value of the parameter \( r_1 \) of Eq. (13). We can imagine in principle - although no examples are known - a system for which the dissipative scale for \( S_n \) is smaller than that for \( S_2 \). In such a system the method will not improve the scaling plots. In this passive scalar model the dissipative scales of all the structure functions are of the same order, as has been shown in (13). This is one of the deep reasons for the success of the method.
in the present case. It is tempting to conjecture that the success of the method in Navier-Stokes turbulence is an indication that the dissipative scales of $S_n$ are either of the same order or become larger with $n$. The full understanding of the method in that case must await a better analytic understanding of the structure functions and their functional form in the near dissipative regime.
