Aims. To explore if attending a psychiatry summer school would change the understanding of school students as to what the word ‘Psychiatry’ represents.

Background. The Institute of Psychiatry, Psychology and Neuroscience (IoPPN) and the local mental health trust, South London and Maudsley NHS Foundation Trust (SLaM) ran a free five-day summer school for 16-year-old school students, who had just completed their GCSE exams, from state and private secondary schools within South-East London.

Method. We asked all 26 student attendees to anonymously write down as many single words relating to ‘Psychiatry’ as they could think of. They were given approximately 5 minutes to complete this and they were asked to do this at the beginning of the first day and at the end of the final day of the summer school. These words were then transcribed with the number of times each word was submitted being documented. This information was then formatted into a word cloud, with the size of the word varying according to how many times it had been submitted.

Result. At the start of the summer school, the students submitted a total of 208 words which included a total of 94 distinct words. Of these, the 2 most common were brain (n = 15) and mental (n = 10). At the end of the summer school, the students submitted a total of 199 words which included a total of 100 distinct words. The 2 most common were psychosis (n = 12) and forensic (n = 8). Of the words submitted pre-summer school, there were 8 distinct words that described positive attributes of psychiatry – such as ‘helping’. This increased to 17 distinct positive words post-summer school.

Conclusion. We note from our outcomes that the number of words submitted by the students pre and post the summer school were similar but the words submitted most frequently differed. The most common words submitted post the summer school were more consistent with medical terminology than those submitted pre the summer school, which suggests that their knowledge of this had increased. The increase in the number of distinct positive words submitted at the end of the summer school implies that the students had a more positive view of psychiatry following the summer school.

Collaborative development of course feedback with students for Psyched Up. Put more in, get more out

Aims. To develop a responsive and sustainable template for long-term course evaluation for Psyched Up

- To obtain rich, meaningful and specific feedback across multiple domains which can be translated into course improvements
- To work collaboratively with students interested in medical education having previously participated in the course
- To empower current students with the knowledge that their input is valuable

Background. Psyched Up is an innovative extra-curricular course for 3rd year medical students at King’s College London delivered by psychiatry trainees, senior students and actors. It is in its second year of running and focuses on the hidden curriculum in medicine, exploration of holistic care and communication skills at the mind-body interface. Input from people with lived experience is used to shape teaching.

Method. Embedded evaluation in course development sessions thus engaging the entire faculty in evaluation processes at the start of the new term

- Decided evaluation focus
- Face-to-face discussions
- Survey for faculty to determine what specific feedback content would be most useful
- Finalised the questionnaire
- Collaborative design and refinement of questions, confirmed sub-sections and scope of questionnaire

Result. Revised questionnaire:

- Included rationale at the start
- Tailored questions so faculty have more useful responses
- Greater quantity of prompted questions
- Specific questions for large group presentation, small group teaching, actors’ performances and students’ reflections
- Thoughtful combination of quantitative ratings and open-space questions
- Reduced time between course sessions and obtainment of feedback
- Quality and quantity of feedback
- High response rates: 32/30 (2 duplicates) mid-term, 29/30 end-of-term
- High-quality filling of open-space feedback allowed consolidation of themes to improve the course

Conclusion. Co-designing the feedback form with previous students from the course and faculty brought focus to the questions. They were more specific and were organised into sub-sections for different domains. This led to responses that were relevant, enriched with depth and breadth and provided faculty with richer, more personalised responses. More detailed reflections in feedback were thought to be due to better student understanding of the rationale for questions, and knowledge that their input would help improve the course. We have set up a robust system for collecting long-term feedback for Psyched Up. We will continue to make iterative amendments, and supplement questionnaire feedback with focus groups.

Psychopharmacology

Peripheral cortisol administration blunts reward arousal but heightens anxiety-like arousal in marmosets

Aims. To examine the therapeutic efficacy and effectiveness of cognitive behavior therapy and pharmacotherapy in the treatment of Major Captagon (Fenethylline) Dependence.

Method. A 41 outpatients males selected for the study, diagnosed as they are suffering from Captagon Dependence according to the DSM-5, with mean age 34.58 ± 5.11. The sample was divided into three experimental groups, (A) (N = 14) treated by cognitive behavior therapy (CBT) and pharmacotherapy in combination. (B) (N = 13) treated by CBT alone. (C) (N = 14) treated by pharmacotherapy alone. All groups were assigned to four measurements, one for the baseline before any treatment interventions, one post-treatment evaluation and two for follow-up within a short and long time. Non-parametric statistics were used to analyze the data collected by SPSS.

Result. There is no significant intra-group differences were found in terms of baseline assessment. There was no significant discrepancy between the first and the second group except in the term of reducing Captagon craving, as it was cleaner in the first group in comparison with other groups. There was a clear significant discrepancy between the first and third groups, for all the study variables and it is phases of assessment especially follow-up. There was a clear degree of differences among the second and the third group, through the different phases of post-assessment, which refers to the great efficacy and effectiveness of CBT in Treating Captagon Dependence CBT was proved to be more effective than pharmacotherapy in the treatment of Captagon Dependence. The combination of CBT and pharmacotherapy was more effective than each other alone in the treatment of Captagon Dependence and Relapse Prevention.

Multicentre evaluation of the pharmacological management of women with bipolar disorder in the perinatal period

Aims. The pharmacological management of women with bipolar disorder in the perinatal period is challenging. This population has a high recurrence rate, but some medications can be a concern in pregnancy and breastfeeding. Little is known about prescribing practices in perinatal services, and the impact of medication on recurrence rates.

The aims of this study are: 1) to describe the use of medication in women with bipolar disorder in the perinatal period and 2) to evaluate the impact of medication on the rate of postpartum recurrence.

Method. Clinical data were collected from pregnant women with a diagnosis of bipolar disorder in the nine participating centres in the UK and who were not experiencing an episode of illness entering the postpartum period. Using a proforma, data were collected for the period between conception and three months postpartum: socio-demographic, reproductive, the severity of illness, medication and recurrence.

Data were analysed for association using χ2 tests and logistic regression.

Result. In this sample of 167 women, 91 (55%) were taking medication at delivery: 62 (37%) antipsychotics, 41 (25%) antidepressants, and 25 (15%) mood stabilisers. In 12 cases medication was reduced before delivery. Of those who were taking medication at delivery six decreased of stopped after delivery and one increased the dose. 42% of women in this sample experienced a recurrence, with 30% of the sample experiencing a manic/psychotic episode. There was no significant association between taking medication and recurrence χ2(1) = 0.07, p = 0.79. There continued to be no association in a multivariable analysis when adjusted for parity, severity (previous admissions, age at first treatment, bipolar...
