MicroRNA-17-5p acts as a biomarker and regulates mitochondrial dynamics in trophoblasts and endothelial cells by targeting the mitofusins Mfn1/Mfn2 in gestational diabetes mellitus

**Abstract**

**Introduction**
Gestational diabetes mellitus (GDM) is a metabolic disease that endangers pregnant women and their offspring. Insights into biomarkers and GDM pathogenesis are crucial. Ectopic expression of microRNA-17-5p was found in GDM, but its diagnostic value and role of miR-17-5p remain unclear.

**Material and methods**
Detection of miRNA microarray and quantitative PCR (qPCR) found that miR-17-5p was significantly increased and positively associated with biochemical indicators of GDM in 30 GDM plasma samples and 28 matched control plasma samples.

**Results**
The area under the ROC curve was 0.827 (P < 0.01), which showed good diagnostic potential. Mitochondrial staining showed that compared with controls, trophoblasts exhibited more mitochondrial fusion and endothelial cells exhibited more mitochondrial fission in GDM than these in controls. Western blot and qPCR assays further revealed that expression of the mitofusin Mfn1/Mfn2 was lower in primary endothelial cells from GDM patients, whereas their expression was significantly higher in primary trophoblasts from GDM patients compared with those from controls. Conversely, miR-17-5p expression was higher in primary endothelial cells from GDM patients, whereas their expression was significantly lower in primary trophoblasts from GDM patients compared with those from controls. Bioinformatics and luciferase reporter assays confirmed that both Mfn1 and Mfn2 are targets of miR-17-5p. Last, decreased Mfn1/2 was observed not only to increase the apoptotic rate of primary endothelial cells from GDM, but also to reverse anti-apoptotic effects of miR-17-5p inhibitor.

**Conclusions**
MiR-17-5p regulates Mfn1/Mfn2-mediated mitochondrial dynamics involved in GDM. MiR-17-5p may serve as a promising biomarker and therapeutic target for GDM.
MicroRNA-17-5p acts as a biomarker and regulates mitochondrial dynamics in trophoblasts and endothelial cells by targeting the mitofusins Mfn1/Mfn2 in gestational diabetes mellitus

Abstract

Background: Gestational diabetes mellitus (GDM) is a metabolic disease that endangers pregnant women and their offspring. Insights into biomarkers and GDM pathogenesis are crucial. Ectopic expression of microRNA-17-5p was found in GDM, but its diagnostic value and role of miR-17-5p remain unclear.

Method and result: Detection of miRNA microarray and qRT-PCR found that miR-17-5p was significantly increased and positively associated with biochemical indicators of GDM in 30 GDM plasma samples and 28 matched control plasma samples. The area under the ROC curve was 0.827 (P < 0.01), which showed good diagnostic potential. Mitochondrial staining showed that compared with controls, trophoblasts exhibited more mitochondrial fusion and endothelial cells exhibited more mitochondrial fission in GDM than these in controls. Western blot and qRT-PCR assays further revealed that expression of the mitofusin Mfn1/Mfn2 was lower in primary endothelial cells from GDM patients, whereas their expression was significantly higher in primary trophoblasts from GDM patients compared with those from controls. Conversely, miR-17-5p expression was higher in primary endothelial cells from GDM patients, whereas their expression was significantly lower in primary trophoblasts from GDM patients compared with those from controls. Bioinformatics and luciferase reporter assays confirmed that both Mfn1 and Mfn2 are targets of miR-17-5p. Last, decreased Mfn1/2 was observed not only to increase the apoptotic rate of primary endothelial cells from GDM, but also to reverse anti-apoptotic effects of miR-17-5p inhibitor.

Conclusion: MiR-17-5p regulates Mfn1/Mfn2-mediated mitochondrial dynamics involved in GDM. MiR-17-5p may serve as a promising biomarker and therapeutic target for GDM.

Key words: MicroRNA-17-5p, Biomarker, Mitofusin, Mitochondrial dynamic, Gestational diabetes mellitus

Introduction
Gestational diabetes mellitus (GDM), which is characterized by glucose intolerance with onset or first recognition during pregnancy, has become a common health problem worldwide in the context of increased obesity [1]. Its incidence is high in Asians, and its prevalence in China is 14.8% [2]. Unless properly diagnosed and treated, GDM can result in short-term and long-term adverse outcomes for both the mother and fetus, including cesarean section, shoulder dystocia, macrosomia, and neonatal hypoglycemia [3]. Although detection of GDM as early as possible is crucial to avoid poor pregnancy outcomes, the current diagnostic test for GDM is an oral glucose tolerance test (OGTT), which is performed at 24-28 weeks of gestation in compliance with the International Association of Diabetes and Pregnancy Study Groups (IADPSG). Thus, the identification of new biomarkers of GDM is anticipated to predict the early diagnosis of GDM and prevent complications, which is vital to minimize the dangers of hyperglycemia in pregnant women and their children. In addition, in order to find effective therapeutic targets, the pathophysiological mechanism of GDM requires further exploration.

Remodeling of the uterine arteries is mediated by extravillous trophoblasts, which penetrate the arterial walls and induce endothelial apoptosis, this is a key event in early pregnancy [4]. Defective remodeling is associated with pregnancy complications, such as preeclampsia and intrauterine growth restriction [5]. The diabetic environment is closely related to endothelial and vascular dysfunction [6], and recently, some miRNAs identified as potential biomarkers of GDM [7] were shown to play an important role in trophoblast-induced endothelial apoptosis [8,9]. Peng et al. reported that high glucose suppresses the viability and proliferation of HTR-8/SVneo cells through regulation of the miR-137/PRKAA1/IL-6 axis [10]. Interestingly, literatures reported that mitochondrial fission associated with hyperglycemia induces endothelial cell apoptosis and blood vessel damage [11,12]. Therefore, these findings urged us to explore whether these miRNAs could be the diagnostic, prognostic, and therapeutic targets in GDM.

Differential expression of some miRNAs (e.g., miR-17-5p, miR-19a-3p, miR-19b-3p, miR-20a-5p) were found in GDM, suggesting to be potential diagnostic markers [13]. However, opposing miR-17-5p expression patterns between plasma (up-regulation) and placental tissues (down-regulation) [14] from GDM patients implied that further research on the potential molecular mechanisms in GDM is still necessary.

Accordingly, in the present study, we studied the expression patterns and diagnostic value of miR-17-5p in a large cohort of GDM patients from the gynaecology and obstetrics departments of Tangshan Gongren Hospital and explored the pathophysiological role of miR-17-5p in trophoblasts and endothelial cells in GDM.

Materials and Methods

Clinical specimens

Thirty GDM-complicated pregnancies and 28 normal pregnant women as control were admitted to the gynaecology and obstetrics departments of Tangshan Gongren Hospital between May 2019 and August 2020 were included in this study. Healthy pregnant women as controls not only have normal OGTT, but also meet matched age, body mass index (BMI) and gestational age. The medical history and examination of all enrolled participants should be complete. Of course, patients with GDM who already started oral hypoglycemic drugs, and
with history of pre-existing type 1 or 2 DM were excluded. All neonates had a birth weight between the 10th and 90th percentile. None of the women showed signs of hypertension or any other disease. Basic clinical data of the subjects are presented in Table 1. Venous blood samples (5 mL) were centrifuged at ~1,000 x g for 30 min at room temperature, and plasma was stored at -80°C until subsequent analysis. GDM patients were diagnosed by OGTT at 28–32 weeks of gestation as previously described [15]. All patients and controls provided written informed consent. According to the agency guidelines, all these patients had got informed consent before sample collection, and to approve the study by the Research Ethics Committee of XXXXX Hospital (the reference number is GRYY-LL-2019-21).

Diagnostic criteria of GDM [15]

The diagnosis of GDM is confirmed using the diagnostic criteria of the IADPSG as followed: fasting plasma glucose (FPG) ≥5.1 mmol/L, 1 h PG ≥10.0 mmol/L, or 2 h PG ≥8.5 mmol/L and then undergo a 75 g oral glucose tolerance test (OGTT).

miRNA profiling in GDM plasma

Plasma specimens were enrolled from pregnancy (3 women with GDM) and 3 controls matched for maternal age and pregnancy period) from the gynaecology and obstetrics departments of Tangshan Gongren Hospital. MiRNA extraction and quantification followed a protocol from miRNasyal kit (Qiagen, Hilden, Germany) and an ND-1000 spectrophotometer (NanoDrop, Rockland, DE, USA). Further, microRNA-seq was performed on the Illumina HiSeq4000 SE50 (Illumina, San Diego, California, USA) after a miRNA library preparation. Differential miRNA expression analysis was performed using DESeq2 software.

Isolation and culture of primary human trophoblasts and endothelial cells

Isolation of primary first-trimester cytotrophoblasts was performed as previously described [16]. Primary human first-trimester decidual ECs were isolated using a modified method described by Grimwood et al [17]. Both primary trophoblasts and endothelial cells were cultured in RPMI1640 culture medium (10% fetal bovine serum) at 37°C, 5% CO₂, and 95% humidity. Purities of primary trophoblast and endothelial cells were identified by cell immunofluorescence staining using using anti-CK7 (marker for trophoblast cells) and anti-CD31 (marker for endothelial cells) antibodies, respectively. Cell experiment has been approved by the Research Ethics Committee of XXXXX Hospital (the reference number is GRYY-LL-2019-21).

Transfection of anti-miR-17-5p or si-Mfn1/2 into endothelial cells

ECs in a 6-well plate (2 × 10⁵ cells/well) were maintained in RPMI1640 culture medium (10% fetal bovine serum, 100 U/ml penicillin and 100 μg/ml streptomycin). For transfection, the anti-miR-17-5p or anti-control (Shanghai Genechem Co., LTD. China) were delivered at a final concentration of 75 nM Lipofectamine® 2000 (Thermo Fisher Scientific, Inc.) following the manufacturer’s instructions. Effectiveness of transfection was performed by qRT-PCR to measure the levels of miR-17-5p at 36 h post-transfection. Specific small interfering RNA targeting Mfn1 (si-Mfn1) and Mfn2 (si-Mfn2) as well as corresponding control (si-con) were also purchased from RiboBio. Transfection was conducted
using Lipofectamine 2000 (Thermo Fisher Scientific) according to the manufacturer’s instructions.

**Real time quantitative PCR (qRT-PCR)**

Total RNA from treated cells and plasma samples was extracted using RNAiso Plus reagent (Takara Bio, Inc.) and TRIzol® LS reagent (Invitrogen; Thermo Fisher Scientific, Inc.), respectively. Then, 0.5 µg total RNA was reverse transcribed into cDNA using a SuperScript® VILO™ cDNA Synthesis Kit and was then used for qRT-PCR with a SYBR Green qPCR Super Mix UDG Kit (Takara Bio, Inc.) according to the corresponding manufacturers' protocols. PCR was performed as follows: 95˚C for 2 min followed by 40 cycles at 95˚C for 15 s, 60˚C for 10 s, and 72˚C for 10 s. The relative expression was calculated using the 2-ΔΔCt formula and was normalized to U6, where ΔCt = Ct related microRNA – Ct U6 and ΔΔCt = ΔCt experimental – ΔCt control. All PCR was performed in triplicate. The primer sequences of miR-17-5p are as follows: forward 5'GCCGCCAAAGTGCTTACA-3', reverse, 5'CAGAGCAGGGTCCGAGGTA-3'; U6: forward 5'CTCGCTTCGGCAGCACA-3' and reverse, 5'AACGCTTCACGAATTTGGT-3'.

**Mitochondrial staining**

Mitochondria were visualized with MitoTracker™ Red kit followed the instruction as previously described [18]. Images were captured by confocal microscopy (Nicon Eclipse E-800). The criteria for mitochondrial fission and fusion as followed: when fused, it can form a long rod-shaped, linear and tightly connected three-dimensional mitochondrial network; when it is split, it can form granular, dot-shaped scattered mitochondria.

**Cell Immunofluorescence**

Protocol of cell immunofluorescence staining was described previously [18]. Briefly, primary human trophoblasts and endothelial cells were fixed by Paraformaldehyde (4%) and permeabilized with 0.1% Triton X-100, then blocked with 5% BSA for 1 h, incubated overnight with the primary antibodies anti-cytokeratin-7(CK-7) (1:100, ab68459, Abcam) and anti-CD31 (1:100, ab24590, Abcam) at 4˚C. Alexa Fluor 568 conjugated secondary antibodies and 4'-6-diamidino-2-phenylindole (DAPI) for staining nuclei were employed. Images were viewed by a fluorescent microscope with 400× magnification.

**Apoptosis assay**

Apoptotic rate of endothelial cells was measured using the Annexin-V FITC apoptosis detection kit (Sigma-Aldrich, Merck, Beijing, China). Briefly, primary endothelial cells (2×10^5/well) were seeded into 12-well plates and cultured for 48 h at 37˚C and then resuspended in HEPES buffer with Annexin-V and PI for detection using flow cytometry (Becton Dickinson, San Jose, CA, USA).

**Western blot**

Western blotting assay was performed as previously described [19]. Briefly, the extracted total protein concentration was determined by a BCA assay. Total protein was separated via SDS-PAGE and then transferred onto PVDF membranes. Non-fat milk for blocking was
followed by incubation overnight at 4˚C with the following primary antibodies: Anti-Mfn1
(1:1,000, 66776-1-lg, Proteintech); anti-Mfn2 (1:1,000, 67487-1-lg, Proteintech) and
anti-β-actin (1:5,000, 20536-1-AP, Proteintech) and goat anti-rabbit secondary antibodies
(SA00001-1, Proteintech). The bonded proteins were visualized by chemiluminescent reaction
with ECL (Amersham Pharmacia Biotech, Inc, Little Chalfont, United Kingdom).

Luciferase reporter gene
A partial sequence of the 3’-UTRs of Mfn1 and Mfn2 as well as the corresponding mutated
miR-17-5p target site in the 3’-UTRs of Mfn1 and Mfn2 were each cloned into the downstream
region of the firefly luciferase gene in the pGL2 Vector (Promega, Madison, WI, USA). 293T
cells (5 x 10^4 cells/well) were seeded in 24-well plates and co-transfected with the vector
(pGL2-Mfn1-WT or pGL2-Mfn1-MUT and pGL2-Mfn2-WT or pGL2-Mfn2-MUT) and miR-NC
mimic or miR-17-5p mimic. After 48 h, the cells were subjected to a dual luciferase assay
(Promega, Madison, WI, USA). Detection of the binding ability of miR-17-5p and the Mfn1 or
Mfn2 3’-UTRs was performed in three separate experiments. Renilla luciferase activity served
as the internal control to normalized luciferase activity.

Statistical analysis
SPSS 23.0 software was used for the statistical analyses. Data are presented as means ±
standard deviations (SD), and the error bars represent SD. For continuous variables, a
comparison between two groups was done using t-test for the normal distribution and
Mann-Whitney U test for the non-normal distribution. Correlation test between two continuous
variables were done by Pearson correlation coefficient. A receiver operating characteristic
(ROC) curve was plotted for miR-17-5p to show the clinical sensitivity and specificity for
possible cut-off values. Significance level was p<0.05.

Results

Up-regulation of miR-17-5p expression in plasma from women with GDM

Using a high-throughput human miRNA microarray, we found the miRNA expression
profiles between 3 GDM plasma specimens and 3 age- and pregnancy-matched normal
plasma specimens, which served as corresponding controls. The results of hierarchical
clustering and qRT-PCR validation showed top 10 up-regulated miRNAs among the 6 samples
(Fig. 1a and 1b).

Subsequently, we expanded the sample size (30 GDM specimens: age range from 25 to
34, 29.4±3.2 years, and responding 28 control: age range from 24 to 33, 28.9±4.1 years) to
confirm increased plasma miR-17-5p expression in GDM. As presented in Fig. 1c, miR-17-5p
expression was significantly higher in plasma from GDM patients than that in controls (P =
0.009). Importantly, the diagnostic value of miR-17-5p in plasma from GDM patients was also
verified by ROC curve analysis. The results showed that the area under the ROC curve (AUC)
was 0.827 and that the sensitivity and specificity were 0.816 and 0.865, respectively (Fig. 1d).

In addition, we also determined whether a high level of miR-17-5p was associated with
biochemical parameters of GDM patients. As shown in Table 2, a significant positive
correlation was observed between miR-17-5p and FBG, HbA1c, and total cholesterol in GDM
patients. These results suggest that miR-17-5p may serve as a promising biomarker for GDM.

Pattern of mitochondrial dynamics in trophoblasts and endothelial cells

Since the association between mitochondrial fission and endothelial apoptosis has been established in diabetes [20], the mechanism by which the expression of miR-17-5p whether affects trophoblast-induced endothelial cell apoptosis, as mediated by mitochondrial dynamics, was determined by visualizing mitochondrial morphology. Purities of primary trophoblast and endothelial cells were identified by cell Immunofluorescence staining using anti-CK7 and anti-CD31 antibodies, respectively (fig. 2a). The results of MitoTracker™ Red staining showed that most mitochondria in trophoblasts from GDM has a rod-like shape (fused mitochondria). In contrast, in endothelial cells from GDM, increased mitochondrial fission was observed, and the number of endothelial cells containing fragmented mitochondria was much higher in GDM patients than in controls (Fig. 2b and 2c). Furthermore, the mitochondrial fusion-related genes targeted by miR-17-5p were predicted online using TargetScan (Fig. 2d), which implied that the pattern of mitochondrial dynamics (Mitofusins, Mfn1/Mfn2) may play different roles in primary trophoblast and endothelial cells from GDM.

Mitochondrial fusion-related Mfn1 and Mfn2 expression is associated with miR-17-5p

To confirm whether Mfn1 and Mfn2 expression is associated with miR-17-5p in different cell types, we detected the expression of these proteins in primary trophoblasts and endothelial cells from GDM and control patients. Western blot and qRT-PCR analysis showed that decreased expression of Mfn1 and Mfn2 as well as increased miR-17-5p expression were observed in endothelial cells from GDM patients compared with controls (Fig. 3a-b). Conversely, increased Mfn1 and Mfn2 expression as well as decreased miR-17-5p expression were observed in trophoblasts from GDM patients compared with controls (Fig. 3c-d). To further determine the effect of miR-17-5p knockdown on Mfn1 and Mfn2 expression, endothelial cells were transfected with anti-miR-17-5p, and then qRT-PCR detection for confirming inhibition of its expression (Fig. 3e). Following that, the results of western blot indicated that compared with control, Mfn1 and Mfn2 expression was increased in anti-miR-17-5p-transfected endothelial cells (Fig. 3f). These data suggest that Mfn1 or/and Mfn2 could be target gene of miR-17-5p.

Mfn1 and Mfn2 are targets of miR-17-5p

To further explore the relationship between miR-17-5p and Mfn1/Mfn2, the specific binding sites of miR-17-5p in the 3'UTRs of Mfn1 and Mfn2 were predicted by the TargetScan prediction website (Fig. 4a). Moreover, the dual luciferase reporter gene assay was performed to verify the results of bioinformatic prediction (Fig. 4b and 4c). Compared with the negative control (NC) mimic group, luciferase activity was significantly decreased in the miR-17-5p mimic group co-transfected with WT-Mfn1 (P < 0.05, Fig. 4b) or WT-Mfn2 (P < 0.01, Fig. 4c), while luciferase activity remained unchanged in the miR-17-5p mimic group co-transfected with the MUT-Mfn1 or MUT-Mfn2 plasmid (both P > 0.05). These results demonstrated that Mfn1 and Mfn2 are target genes of miR-17-5p.

Down-regulation of Mfn1/2 is required for miR-17-5p-mediated cell apoptosis in endothelial...
To examine whether miR-17-5p-mediated apoptotic effects on endothelial cells is Mfn1/2-dependent process, the rescue experiments were performed. We firstly showed the introduction of si-Mfn1/2 for decreased Mfn1 and Mfn2 expression in endothelial cells (Fig. 5a). Subsequently, the results of flow cytometry showed that down-regulation of Mfn1/2 expression promoted cell apoptosis in primary endothelial cells from GDM compared with si-con group; moreover, decreased miR-17-5p exerted anti-apoptotic effect on primary endothelial cells from GDM. Importantly, down-regulation of Mfn1 or Mfn2 expression dramatically reversed the inhibitory effects of anti-miR-17-5p on the apoptosis rate of endothelial cells from GDM (Fig. 5b). These results indicated that Mfn1 and Mfn2 are downstream targets of miR-17-5p regulating apoptosis of endothelial cells.

Discussion

Trophoblast induction of endothelial cell apoptosis is an important mechanism in spiral artery remodeling in early normal pregnancy [21], but the mechanism in complicated pregnancies, such as in patients with GDM, has yet to be determined. MicroRNAs play a key role in many pathophysiological processes, especially by acting as circulating biomarkers and modulators of the proliferation, migration, invasion, and apoptosis of trophoblasts and endothelial cells [8]. The main objective of this study was to verify the clinical significance and application of circulating miR-17-5p in GDM patients and to elucidate the possible molecular mechanism of miR-17-5p in the regulation of mitochondrial dynamics involved in trophoblast-induced endothelial cell apoptosis. We demonstrated that circulating miR-17-5p is a promising biomarker of GDM since it targets Mfn1/Mfn2-mediated regulation of mitochondrial dynamics. This includes up-regulation of miR-17-5p expression in endothelial cells from GDM patients, which induces mitochondrial fission by decreasing Mfn1/Mfn2 expression, whereas down-regulation of miR-17-5p expression in trophoblasts from GDM patients induces mitochondrial fusion by reversing the inhibitory effects of Mfn1/Mfn2. This leads to acceleration of trophoblast-induced endothelial cell apoptosis in GDM.

It is well known that fetal trophoblasts in early pregnancy invade the luminal surfaces of the endothelium and replace the endothelial lining to create high-flow, low-resistance vessels for nutritional demands of the fetus [4]. Previous studies had reported increased miR-17-5p in plasma [13] and decreased expression in placental tissues [14] in GDM patients, which implies that ectopic expression of miR-17-5p in trophoblasts and endothelial cells is involved in aberrant remodeling of the uterine arteries in GDM. At present, the associated mechanism is still lacking, besides up-regulation of miRNA17-5p expression in plasma from GDM women, even at 16–19 weeks of pregnancy is positively correlated with insulin resistance, a risk factor of GDM. Mitochondrial dynamics mediate the regulation of cell proliferation, migration, and apoptosis associated with miRNAs [22,23]. Thus far, less is known about the role of miRNA17-5p in mitochondrial fission and apoptosis between trophoblasts and endothelial cells in GDM patients. In this study, we examined the effect of miR-17-5p ectopic expression on the regulation of mitochondrial dynamics as they relate to invading trophoblasts, which induce endothelial cell apoptosis in GDM. Our results showed that alteration of miR-17-5p expression in different cells facilitates the migration of trophoblasts and apoptosis of endothelial cells in GDM as a result of an imbalance in mitochondrial dynamics. Decreased miR-17-5p promotes
more mitochondrial fusion in trophoblasts, while increased miR-17-5p promotes more
mitochondrial fission in endothelial cells, which may be a possible mechanism of nutrient
oversupply. This in turn leads to macrosomia and other fetal and maternal complications.

Offspring born to diabetic mothers are at risk of metabolic diseases associated with
mitochondrial dysfunction. Mfn1/Mfn2 are potent modulators of mitochondrial metabolism and
insulin signaling and play a key role in mitochondrial dynamics [24,25]. Some literatures
indicate that Mfn1 is a major mediator contributing to glucose metabolic
reprogramming in cancers [26,27]. Meanwhile, Mfn2 over-expression also leads to
cell invasion in lung adenocarcinoma and gastric cancer [28, 29], implying that
up-regulation of Mfn1/2 prompting more aggressive in trophoblasts, in turn
accelerating the apoptosis of endothelial cells in GDM patients. Notably, a recent study
showed that miR-20b suppresses mitochondrial dysfunction-mediated apoptosis to alleviate
hyperoxia-induced acute lung injury by directly targeting Mfn1 and Mfn2 [30]. This is in line
with our miRNA microarray, which showed up-regulation of miR-20 in plasma from GDM
patients. This suggests that up-regulation of both miR-20 and miR-17-5p may play a role in
endothelial cell apoptosis induced by excessive oxygen and hyperglycemia. These results
presented that miR-17-5p, as a promising biomarker, was selectively expressed in GDM and
targets Mfn1/Mfn2-mediated mitochondrial dynamics to intervene different cell type-dependent
roles. In addition, recent report showed that miRNAs could manipulate nutrition metabolism,
especially glucose and lipid metabolism, by regulating insulin signaling pathways,
mitochondrial abnormalities-associated energy metabolism [31], considering the linking
between miRNA17-5p-mediated mitochondrial fission and insulin resistance in GDM, prone to
hypothesis that miRNA17-5p-mediated nutrition and ATP metabolisms could play a critical role
in the pathophysiological mechanism, still deserving further discussion.

Overall, our findings provide convincing evidences that miR-17-5p exerts bidirectional
regulatory effects on the migration of trophoblasts and the apoptosis of endothelial cells by
targeting the expression of the mitofusins Mfn1/Mfn2 in GDM.

Acknowledgments
We thank Prof. Dong Ma for technical assistance.

Author contributions
L. J., L. Z. H., S. Y. N., W. T., L. S., Z. L. C. and O. Y. X. L. performed the experiments and analyzed the data; L. J., S. Y. N. and L. Z. H. conceived and supervised the study; L. J. and S. Y. N. wrote the manuscript.

Funding
This work was supported by Medical Science Research Projects of Hebei Provincial Health Commission (No. 20201495).

Availability of data and materials
All data produced or analyzed during this study are included in this published article.
Declarations

Ethics approval and consent to participate
Venous blood samples, isolation and culture of primary human trophoblasts and endothelial cells were obtained from patients undergoing surgical resection upon informed consent and approval by the Research Ethics Committee of Tangshan Gongren Hospital (approval number: GRYY-LL-2019-21).

Consent for publication
Not applicable.

Competing interests
The authors state that they have no competing interests.

Figure legends

Figure 1 Up-regulation of miR-17-5p expression in the plasma from GDM patients. a, Hierarchical clustering shows distinguishable miRNA expression (top 10 up-regulated miRNAs) among the 6 samples (3 GDM plasma specimens and 3 age- and pregnancy-matched normal plasma specimens, which served as corresponding controls). b, qRT-PCR for verification of different miRNAs expressed in the six samples. *P < 0.05 and **P < 0.01 vs. control, n = 3 for each group. c, qRT-PCR to detect the miR-17-5p level in plasma from GDM patients (n = 30) and controls (n = 28). **P < 0.01 vs. control. d, Receiver operating characteristic (ROC) curve of circulating miR-17-5p was constructed to predict the diagnostic potential of miR-17-5p for GDM.

Figure 2 Mitochondrial dynamics of trophoblasts and endothelial cells. a, Trophoblasts were derived from primary human first-trimester extravillous trophoblasts, while primary HUVECs were isolated from fresh umbilical cord veins after digestion with collagenase. Representative images of primary trophoblast and endothelial cells purities identified by cell immunofluorescence staining using anti-CK7 (marker for trophoblast cells) and anti-CD31 (marker for endothelial cells) antibodies, respectively. Scale bars = 50 μm. b, MitoTracker™ Red-stained mitochondria with DAPI for nuclear staining (blue) were observed in primary trophoblasts and endothelial cells from GDM and Control women. Scale bars = 10 μm. c, Statistical analysis for the percentage of cells containing fused and fragmented mitochondria from more than 100 cells between two groups. **P < 0.01 and ***P < 0.001 vs. control, n = 3 for each group. d, The miR-17-5p-target regulatory network was constructed based on the TargetScan website (http://www.targetscan.org/vert_72/).

Figure 3 Association between abnormal expression of Mfn1, Mfn2, and miR-17-5p in trophoblasts and endothelial cells. a, Western blot for the detection of Mfn1 and Mfn2 expression in primary endothelial cells from GDM and control patients. β-actin served as a loading control. b, qRT-PCR to detect the miR-17-5p level in primary endothelial cells from GDM and control patients. **P < 0.01 vs. control. c, Western blot for the detection of Mfn1 and Mfn2 expression in primary trophoblasts from GDM and control patients. d, qRT-PCR to detect
the miR-17-5p level in primary trophoblasts from GDM and control patients. *P < 0.05 vs. control. e, RT-qPCR for the decreased miR-17-5p expression in anti-miR-17-5p-transfected endothelial cells compared to anti-control-transfected endothelial cells. ***P < 0.001 vs. control. f, Western blotting assay for expression of Mfn1, Mfn2 in endothelial cells treated as above. β-actin served as a loading control.

**Figure 4 MiR-17-5p targets Mfn1 and Mfn2 expression.** a, The 3′-UTRs (untranslated regions) sequence for the binding of miR-17-5p to Mfn1/Mfn2. b and c, 293A cells were transfected with the reporter directed by the Mfn1 and Mfn2 3′UTR containing the miR-17-5p binding site, and luciferase activity was measured. *P < 0.05 and **P < 0.01 vs. NC mimic group.

**Figure 5 Mfn1/2 expression silencing reverses the anti-apoptosis of miR-17-5p inhibitor in primary endothelial cells from GDM.** a, The protein level of Mfn1/2 was detected in anti-miR-17-5p-transfected endothelial cells from GDM with Mfn1 and Mfn2 silencing or without by Western blotting assay. b, The apoptosis rates were also analysed in above condition by flow cytometry with PI/AnnexinV-FITC. Transfection of anti-control (blue) and anti-miR-17-5p (red) in cells indicated different color column. Data were shown as mean±SD, *P < 0.05 and **P < 0.01 vs. control or anti-miR-17-5p group.
### Table 1 Basic clinical data of the subjects in GDM and Control group

| Parameter                  | GDM (n=30)          | Control (n=28) | P value |
|----------------------------|---------------------|----------------|---------|
| Age (years)                | 29.4±3.2            | 28.9±4.1       | 0.814   |
| BMI (kg/m²)                | 23.8±0.91           | 23.6±1.08      | 0.862   |
| FBG (mmol/L)               | 8.11±1.23           | 4.85±0.77      | <0.001  |
| 1h-PPBG (mmol/L)           | 12.3±1.34           | 8.94±0.66      | <0.001  |
| HbA1c (%)                  | 8.97±1.4            | 4.17±1.1       | <0.001  |
| Total cholesterol (mmol/L) | 5.92±1.34           | 4.33±1.01      | <0.01   |
| HDL (mmol/L)               | 1.22±0.25           | 1.16±0.21      | 0.103   |
| LDL (mmol/L)               | 2.59±0.53           | 2.77±0.46      | 0.029   |
| TGs (mmol/L)               | 2.31±0.68           | 1.92±0.51      | 0.087   |

Note: Data was shown as mean ± standard deviation. BMI, body mass index; FBG, fasting blood glucose; PPBG, post-prandial blood glucose; HbA1c, glycated hemoglobin; LDL, low density lipoprotein cholesterol; HDL, high density lipoprotein cholesterol; TGs, triglycerides.

### Table 2 Association between miR-17-5p levels and the biochemical parameters in GDM patients

| Parameters                  | FBG      | 2h-PPBG  | HbA1c   | Total cholesterol | LDL     | HDL     | TGs     |
|-----------------------------|----------|----------|---------|-------------------|---------|---------|---------|
| miR-17-5p                   | 0.473    | 0.412    | 0.558   | 0.486             | 0.31    | -0.16   | 0.23    |
| r                           | <0.001   | <0.001   | <0.007  | <0.001            | 0.023   | 0.096   | 0.037   |

Note: FBG, fasting blood glucose; PPBG, post-prandial blood glucose; HbA1c, glycated hemoglobin; LDL, low density lipoprotein cholesterol; HDL, high density lipoprotein cholesterol; TGs, triglycerides.
