Increasing evidence suggests that mitoNEET, a target of the type II diabetes drug pioglitazone, is a key regulator of energy metabolism in mitochondria. MitoNEET is anchored to the mitochondrial outer membrane via its N-terminal α helix domain and hosts a redox-active [2Fe-2S] cluster in its C-terminal cytosolic region. The mechanism by which mitoNEET regulates energy metabolism in mitochondria, however, is not fully understood. Previous studies have shown that mitoNEET specifically interacts with the reduced flavin mononucleotide (FMNH₂) and that FMNH₂ can quickly reduce the mitoNEET [2Fe-2S] clusters. Here we report that the reduced mitoNEET [2Fe-2S] clusters can be readily oxidized by oxygen. In the presence of FMN, NADH, and flavin reductase, which reduces FMN to FMNH₂ using NADH as the electron donor, mitoNEET mediates oxidation of NADH with a concomitant reduction of oxygen. Ubiquinone-2, an analog of ubiquinone-10, can also oxidize the reduced mitoNEET [2Fe-2S] clusters under anaerobic or aerobic conditions. Compared with oxygen, ubiquinone-2 is more efficient in oxidizing the mitoNEET [2Fe-2S] clusters, suggesting that ubiquinone could be an intrinsic electron acceptor of the reduced mitoNEET [2Fe-2S] clusters in mitochondria. Pioglitazone or its analog NL-1 appears to inhibit the electron transfer activity of mitoNEET by forming a unique complex with mitoNEET and FMNH₂. The results suggest that mitoNEET is a redox enzyme that may promote oxidation of NADH to facilitate enhanced glycolysis in the cytosol and that pioglitazone may regulate energy metabolism in mitochondria by inhibiting the electron transfer activity of mitoNEET.

Pioglitazone is a drug prescribed for the treatment of type II diabetes (1). In addition to acting on peroxisome proliferator-activated receptor γ (PPARγ), which regulates the expression of genes related to insulin sensitivity (2), pioglitazone also has a rapid pharmacological effect on energy metabolism in mitochondria (3). A search of pioglitazone-binding targets revealed a new protein, mitoNEET, that localizes in the mitochondrial outer membrane (4). In mice, deletion of mitoNEET results in a decrease in oxidative phosphorylation capacity in mitochondria by about 30% (5). On the other hand, overexpression of mitoNEET enhances lipid storage and decreases oxidative damage in adipocytes (6, 7) and inhibits ferroptosis in human hepatocellular carcinoma cells (8). In β cells, increased expres-
Electron transfer activity of mitoNEET

In previous studies, we have found that human mitoNEET has a specific interaction with the reduced flavin mononucleotide (FMNH\(_2\)) and that FMNH\(_2\) can rapidly reduce the mitoNEET [2Fe-2S] clusters (29). Here we report that the reduced mitoNEET [2Fe-2S] clusters can be oxidized by oxygen or ubiquinone-2. Compared with oxygen, ubiquinone-2 appears to be more efficient in oxidizing the mitoNEET [2Fe-2S] clusters, indicating that ubiquinone may act as a native electron acceptor of the reduced mitoNEET [2Fe-2S] clusters in mitochondria. In the presence of flavin reductase, which reduces FMN to FMNH\(_2\) using NADH as the electron donor, mitoNEET mediates oxidation of NADH with a concomitant reduction of oxygen or ubiquinone-2. Furthermore, pioglitazone can effectively inhibit the electron transfer activity of mitoNEET by forming a unique complex with mitoNEET and FMN\(_2\). The results led us to propose that mitoNEET is a redox enzyme that may promote oxidation of NADH to enhance glycolysis in the cytosol and that pioglitazone may regulate energy metabolism in mitochondria by inhibiting the electron transfer activity of mitoNEET.

Results

Reduction of the mitoNEET [2Fe-2S] clusters under anaerobic and aerobic conditions

Previous studies have shown that human mitoNEET has a specific interaction with FMNH\(_2\) and that FMNH\(_2\) can quickly reduce the mitoNEET [2Fe-2S] clusters (29). As oxygen would be present in mitochondria, we asked whether oxygen will have any effects on the FMNH\(_2\)-mediated reduction of the mitoNEET [2Fe-2S] clusters.

To test this idea, human mitoNEET was preincubated with FMN and NADH under anaerobic or aerobic conditions. The reaction was initiated by adding a catalytic amount of Escherichia coli flavin reductase (32) to reduce FMN using NADH as the electron donor (29). Fig. 1A shows that, under anaerobic conditions, the oxidized mitoNEET [2Fe-2S] clusters (indicated by the absorption peaks at 455 nm and 540 nm (27)) were quickly reduced upon addition of flavin reductase, as reported previously (29). About 10 \(\mu\)M NADH was oxidized when 10 \(\mu\)M mitoNEET [2Fe-2S] clusters were reduced in the incubation solution under anaerobic conditions (Fig. 1C). Under aerobic conditions, the mitoNEET [2Fe-2S] clusters were also fully reduced after addition of flavin reductase (Fig. 1B). However, NADH was continuously oxidized even after the mitoNEET [2Fe-2S] clusters were fully reduced (Fig. 1C). The observed oxidation of NADH was mitoNEET-dependent, as only a very small amount of NADH was oxidized in the same incubation solution without mitoNEET under aerobic conditions (Fig. 1D). Thus, mitoNEET is able to promote oxidation of NADH in the presence of flavin reductase and FMN under aerobic conditions.

The reduced mitoNEET [2Fe-2S] clusters are oxidized by oxygen under aerobic conditions

In the presence of flavin reductase, FMN and excess NADH, the mitoNEET [2Fe-2S] clusters were fully reduced under aerobic conditions (Fig. 1B). One explanation could be that the reduced mitoNEET [2Fe-2S] clusters are oxidized by oxygen and rapidly rereduced by FMNH\(_2\)/NADH/flavin reductase under aerobic conditions.

To test this idea, mitoNEET was incubated with a limited amount of NADH and FMN under aerobic conditions. As shown in Fig. 2, the mitoNEET [2Fe-2S] clusters were fully reduced upon addition of a catalytic amount of flavin reductase. However, when NADH in the incubation solution was completely oxidized, the reduced mitoNEET [2Fe-2S] clusters were gradually reoxidized under aerobic conditions, demonstrating that the reduced mitoNEET [2Fe-2S] clusters are indeed oxidized by oxygen under aerobic conditions.

The reduced mitoNEET [2Fe-2S] clusters can also be oxidized by ubiquinone-2 under anaerobic conditions

In mitochondria, NADH-ubiquinone oxidoreductase (complex I) oxidizes NADH and reduces ubiquinone via FMN and a chain of iron-sulfur clusters (33). Ubiquinone is a key electron transport component in the respiratory chain (34) and is present in both the mitochondrial inner and outer membranes (35). As mitoNEET is a mitochondrial outer membrane protein (4), and the [2Fe-2S] clusters in mitoNEET are positioned close to the membrane (18–21), we postulated that the reduced mitoNEET [2Fe-2S] clusters may also reduce ubiquinone in the mitochondrial outer membrane.
In the experiments, the mitoNEET [2Fe-2S] clusters were prereduced with flavin reductase, FMN, and an excess amount of NADH under anaerobic conditions. Ubiquinone-2, a ubiquinone-10 analog, was then injected into the incubation solution anaerobically using a gas-tight syringe. Fig. 3 shows that the reduced mitoNEET [2Fe-2S] clusters were immediately oxidized upon injection of ubiquinone-2 under anaerobic conditions. As a control, injection of degassed water had no effect on the reduced mitoNEET [2Fe-2S] clusters (data not shown). After further incubation, the ubiquinone-2-oxidized mitoNEET [2Fe-2S] clusters were fully rereduced in the incubation solution (Fig. 3A), suggesting that oxidation of the mitoNEET [2Fe-2S] clusters by ubiquinone-2 is reversible.

We also tested whether the reduced mitoNEET [2Fe-2S] clusters could be oxidized by other oxidants. In the experiments, the mitoNEET [2Fe-2S] clusters were prereduced with flavin reductase, FMN, and an excess amount of NADH under anaerobic conditions, followed by injection of oxidants anaerobically. We found that dichloroindophenol, K₃Fe(CN)₆, or menadione could all quickly oxidize the reduced mitoNEET [2Fe-2S] clusters (supplemental Fig. 1), suggesting that the reduced mitoNEET [2Fe-2S] clusters may also be oxidized by other oxidants in the cytosol. Oxidation of the mitoNEET [2Fe-2S] clusters by dichloroindophenol or K₃Fe(CN)₆ was very similar to that of ubiquinone-2. However, menadione appeared to be less active to oxidize the mitoNEET [2Fe-2S] clusters under the experimental conditions (supplemental Fig. 1). Because ubiquinone is a physiologically oxidant and is in the vicinity of the mitoNEET [2Fe-2S] clusters in mitochondria, we propose that ubiquinone could be a native electron acceptor for the reduced mitoNEET [2Fe-2S] clusters in mitochondria.

**Oxidation of the reduced mitoNEET [2Fe-2S] clusters by ubiquinone-2 under aerobic conditions**

Compared with oxygen (Fig. 2), ubiquinone-2 is much more efficient in oxidizing the reduced mitoNEET [2Fe-2S] clusters (Fig. 3A). To further explore the reactivity of the reduced mitoNEET [2Fe-2S] clusters with oxygen and ubiquinone-2, we incubated mitoNEET with FMN, NADH, and ubiquinone-2 under aerobic conditions. Fig. 4A shows that NADH was continuously oxidized after flavin reductase was added to the incubation solution. The observed NADH oxidation was mitoNEET-dependent, as only a very small amount of NADH was oxidized in the incubation solution without mitoNEET under aerobic conditions (Fig. 4B). Importantly, despite oxidation of NADH in the incubation solution containing ubiquinone-2, the mitoNEET [2Fe-2S] clusters remained oxidized during the incubation process (Fig. 4A). This result indicates that the reduced mitoNEET [2Fe-2S] clusters might be rapidly oxidized by ubiquinone-2, which subsequently transfers electron to oxygen under aerobic conditions. Indeed, when the incubation solution in Fig. 4A was purged with pure argon gas to remove oxygen, the mitoNEET [2Fe-2S] clusters were re-reduced upon addition of NADH (Fig. 4, C and D). Thus, the results further suggest that ubiquinone in mitochondria may act as an intrinsic electron acceptor for the mitoNEET [2Fe-2S] clusters under anaerobic or aerobic conditions.

**A pioglitazone analog, NL-1, inhibits the electron transfer activity of mitoNEET**

MitoNEET was identified as a target of the type II diabetes drug pioglitazone (1). However, pioglitazone has a very low solubility in water (<1 mg/ml), making it difficult to characterize its biochemical activity (28). A new pioglitazone analog, NL-1 or 5-(3,5-di-tert-butyl-4-hydroxybenzyl)-4-hydroxythiazol-2(5H)-one, was designed and synthesized by Geldenhuys et al. (36). NL-1 has been improved for its solubility in water and binding specificity to mitoNEET. It has similar pharmacological activities as pioglitazone to decrease the maximal respiration rate of mitochondria by 45%, reduce the production of reactive oxygen species (36), and improve the survival of cardiac stem cells during oxidative stress (37).
Electron transfer activity of mitoNEET

Here we explored the effect of NL-1 on the electron transfer activity of mitoNEET. In the experiments, mitoNEET was preincubated with increasing concentrations of NL-1 under aerobic conditions, followed by addition of flavin reductase and FMN. GSH. The reaction was initiated by addition of NADH. The amount of the reduced mitoNEET [2Fe-2S] clusters was measured from the absorption peak at 340 nm. The data are representative of three independent experiments.

Pioglitazone/NL-1 and FMNH₂ forms a unique complex with the reduced mitoNEET [2Fe-2S] clusters

To further assess the effects of pioglitazone and its analog NL-1 on the electron transfer activity of mitoNEET, mitoNEET was incubated with FMN, pioglitazone, NL-1, or combinations at room temperature for 1 h under aerobic conditions. The samples were then reduced with sodium dithionite for electron paramagnetic resonance (EPR)² measurements of the reduced mitoNEET [2Fe-2S] clusters. Fig. 6A shows that incubation with FMNH₂ results in a small EPR signal at g = 1.85 of the reduced mitoNEET [2Fe-2S] clusters (spectrum 2), as reported previously (29). However, unlike FMNH₂, incubation with pioglitazone (4) (Fig. 6A, spectrum 3) or NL-1 (36) (Fig. 6A, spectrum 4) did not change the EPR spectrum of the reduced mitoNEET [2Fe-2S] clusters. Nevertheless, incubation of mitoNEET with FMNH₂ and pioglitazone completely shifted the typical EPR spectrum at g = 1.94 of the reduced mitoNEET [2Fe-2S] clusters to a new EPR spectrum with g = 1.85 (Fig. 6A, spectrum 5). The same result was also observed when mitoNEET was incubated with FMNH₂ and NL-1 (Fig. 6A, spectrum 6). While a small EPR signal at g = 1.86 of the reduced mitoNEET [2Fe-2S] clusters was noticed previously (38), the interpretation of the EPR signal at g = 1.85 remains elusive. Nevertheless, the dramatic change of the EPR spectrum strongly suggests that FMNH₂ and pioglitazone/NL-1 may have a close interaction with the reduced [2Fe-2S] clusters in mitoNEET or that binding of FMNH₂ and pioglitazone/NL-1 may result in conformational changes that alter the structural orientation of the cluster ligands in mitoNEET.

MitoNEET was further incubated with a fixed concentration of FMN and increasing concentrations of NL-1 at room temperature for 1 h under aerobic conditions, followed by reduction with sodium dithionite. Fig. 6B shows that, as the concentration of NL-1 increased, the EPR spectrum at g = 1.85 gradually increased. About 200 μM NL-1 was sufficient to change the EPR spectrum of g = 1.94 to that of g = 1.85 of the reduced mitoNEET [2Fe-2S] clusters. The results suggest that FMNH₂ and pioglitazone/NL-1 have a synergistic effect on the reduced mitoNEET [2Fe-2S] clusters.

²The abbreviations used are: EPR, electron paramagnetic resonance; Fre, flavin reductase; g, the g-factor of an unpaired electron.
Figure 6. Synergistic effect of FMNH2 and pioglitazone/NL-1 on the reduced mitoNEET [2Fe-2S] clusters. A, EPR spectra of the reduced mitoNEET [2Fe-2S] clusters. MitoNEET (containing 20 μM [2Fe-2S] clusters, spectrum 1) was incubated with FMN (50 μM, spectrum 2), pioglitazone (Pio, 500 μM, spectrum 3), NL-1 (200 μM, spectrum 4), FMN + pioglitazone (spectrum 5), and FMN + NL-1 (spectrum 6) at room temperature for 60 min. After incubation, samples were reduced with freshly prepared sodium dithionite (4 mM), transferred to EPR tubes, and immediately frozen in liquid nitrogen for EPR measurements. B, titration of NL-1. MitoNEET (containing 20 μM [2Fe-2S] clusters) was incubated with FMN (50 μM) and increasing concentrations of NL-1 (0 to 200 μM) (spectra 1–5) at room temperature for 60 min. After incubation, samples were reduced with freshly prepared sodium dithionite (4 mM), transferred to EPR tubes, and immediately frozen in liquid nitrogen for EPR measurements. The data are representative of three independent experiments.

Discussion

MitoNEET is a founding member of a small family of proteins that contain a CDGSH motif (39, 40). Although it has been reported that mitoNEET is a key regulator of energy metabolism in mitochondria (13), the underlying mechanism has not been fully understood. Several research groups proposed that mitoNEET may transfer its [2Fe-2S] clusters for maturation of iron–sulfur proteins in the cytosol (22–24). Others suggested that mitoNEET may regulate mitochondrial functions via specific protein–protein interactions (9). Here we report that mitoNEET is a novel redox enzyme that transfers electron from FMNH2 to oxygen or ubiquinone in the mitochondrial outer membrane via its [2Fe-2S] clusters. In this process, FMNH2, which may be reduced by flavin reductase (41) and NADH in the cytosol, binds to mitoNEET and reduces the [2Fe-2S] clusters in mitoNEET (29). The reduced mitoNEET [2Fe-2S] clusters are readily oxidized by oxygen or ubiquinone (Fig. 7). Together with flavin reductase (41) and FMN, mitoNEET may effectively promote oxidation of NADH in the cytosol with a concomitant reduction of oxygen or ubiquinone in the mitochondrial outer membrane.

The intracellular concentration of FMN in human cells is in the nanomolar range (42). Here we found that 100 nM FMN is sufficient to reduce 10 μM mitoNEET [2Fe-2S] clusters in the presence of flavin reductase and NADH in less than 2 min (Fig. 1), indicating that FMN may act as an electron shuttle, reducing the mitoNEET [2Fe-2S] clusters (29). In the cytosol, FMN is reduced to FMNH2 by flavin reductase (41), using NADH as the electron donor. Because glycolysis will produce NADH, which must be oxidized to sustain glycolysis activity (43), mitoNEET may enhance glycolysis by promoting oxidation of NADH in the cytosol (Fig. 7). In primary and metastatic cancer cells, glycolysis is highly up-regulated, resulting in increased glucose consumption (44). Interestingly, mitoNEET is also highly expressed in cancer cells, and overexpression of mitoNEET is essential for cancer cell proliferation (11, 12). In this context, we propose that overproduced mitoNEET may enhance glycolysis in the cytosol by promoting oxidation of NADH in cancer cells. Accordingly, when mitoNEET is deleted, oxidation of NADH in the cytosol could be diminished, leading to a decrease in glycolysis in the cytosol and oxidative phosphorylation in mitochondria. This notion is consistent with a previous report showing that deletion of mitoNEET decreases the oxidative phosphorylation capacity in mitochondria by about 30% (5) and inhibits cancer cell proliferation (11, 12). Nevertheless, additional experiments are required to elucidate the physiological link between the electron transfer activity of mitoNEET and glycolysis in cells.

Iron-sulfur clusters in proteins are often sensitive to oxygen and reactive oxygen species (45). However, the mitoNEET [2Fe-2S] clusters are highly resistant to oxygen and hydrogen peroxide (27). In fact, the reduced mitoNEET [2Fe-2S] clusters can be oxidized by oxygen without disruption of the cluster (Fig. 2). Importantly, compared with oxygen, ubiquinone-2 is more efficient in oxidizing the reduced mitoNEET [2Fe-2S] clusters (Figs. 3 and 4). Because mitoNEET is a mitochondrial outer membrane protein (4), and the [2Fe-2S] clusters in mitoNEET are positioned close to the membrane (18–21), we propose that ubiquinone could be an intrinsic electron acceptor for the reduced mitoNEET [2Fe-2S] clusters (Fig. 7). Upon the single-electron reduction by the reduced mitoNEET [2Fe-2S] cluster, ubiquinone is converted to semiquinone, which may be further reduced to ubihydroquinone, or transfer the electron to oxygen to produce superoxide or hydrogen peroxide (34). Although other oxidants in the cytosol may also oxidize the reduced mitoNEET [2Fe-2S] clusters in the cytosol, the proposed electron transfer path from NADH to ubiquinone catalyzed by the mitoNEET [2Fe-2S] clusters (Fig. 7) is reminiscent of the electron transfer path in complex I, in which electrons in NADH are transferred to ubiquinone via FMN and a chain of iron–sulfur clusters (33). The observed reduction of oxygen by the mitoNEET [2Fe-2S] clusters may reflect the possible electron transfer leak in mitoNEET, as reported in complex I (33). The final products of the electron transfer reaction catalyzed by mitoNEET in mitochondria remain to be determined.
Electron transfer activity of mitoNEET

Pioglitazone has two major targets in cells: peroxisome proliferator-activated receptor γ, which regulates the expression of genes involved in insulin sensitivity (2), and mitoNEET (4), which modulates energy metabolism in mitochondria (3). It was reported previously that binding of pioglitazone stabilizes the mitoNEET [2Fe-2S] clusters (21) and shifts the redox midpoint potential of the [2Fe-2S] clusters by about 100 mV (26). Here we found that pioglitazone and its analog NL-1 (36) can inhibit the electron transfer activity of mitoNEET (Fig. 5) by forming a unique complex with mitoNEET and FMNH$_2$ that has an unusual EPR signal at $g = 1.85$ (Fig. 6). Based on molecular docking modeling (29, 36), FMN and pioglitazone/NL-1 have distinct binding sites but with significant overlap in mitoNEET, suggesting that pioglitazone/NL-1 may interfere with FMNH$_2$ binding in mitoNEET and inhibit the electron transfer activity of mitoNEET in mitochondria. As mitoNEET is proposed as a chemotherapeutic target for treating type II diabetes (4), breast cancer (16, 17), and neurodegenerative diseases (10), a high-throughput screening approach combining the electron transfer activity assay and EPR measurements of mitoNEET may help identify new drugs that specifically target the mitoNEET [2Fe-2S] clusters in mitochondria.

Experimental procedures

Protein preparation

The human mitochondrial outer membrane protein mitoNEET$_{33–108}$ (containing residues 33–108) was purified as described in Ref. 28. E. coli flavin reductase (Fre) was prepared using an E. coli strain hosting an expression plasmid encoding Fre from the ASKA (A Complete Set of E. coli K-12 ORF Archive) library (46). Both mitoNEET and Fre were overproduced in E. coli cells and purified using nickel-agarose columns, followed by passing through a High-Trap desalting column. The purity of purified proteins was greater than 95%, as judged by electrophoresis analysis on a 15% polyacrylamide gel containing SDS followed by staining with Coomassie Blue. The protein concentrations of mitoNEET and E. coli Fre were measured at 280 nm using the molar extinction coefficients of 8.6 and 26.4 mm$^{-1}$cm$^{-1}$, respectively. The molar extinction coefficients were calculated based on the protein primary sequence.

Redox state of the mitoNEET [2Fe-2S] clusters

Reduction and oxidation of the mitoNEET [2Fe-2S] clusters in incubation solutions were monitored using a Beckman DU640 UV-visible absorption spectrometer equipped with a temperature controller. Oxidized mitoNEET [2Fe-2S] clusters have two major absorption peaks at 455 nm and 540 nm, whereas reduced mitoNEET [2Fe-2S] clusters have absorption peaks at 420 nm and 540 nm (29). The redox state of the mitoNEET [2Fe-2S] clusters was further determined by EPR measurements. Oxidation of NADH in the incubation solution was monitored at 340 nm after subtracting the basal absorption of proteins in the incubation solution. Anaerobic conditions were achieved by purging the incubation solutions with pure argon gas for 15 min in a sealed vial.

EPR measurements

The X-band EPR spectra were recorded using a Bruker model ESR-300 spectrometer equipped with an Oxford Instruments 910 continuous flow cryostat. Routine EPR conditions were as follows: microwave frequency, 9.47 GHz; microwave power, 10.0 milliwatt; modulation frequency, 100 kHz; modulation amplitude, 1.2 millitesla; temperature, 30 K; receiver gain, $2 \times 10^5$.

Chemicals

NADH, NADPH, isopropyl β-D-thiogalactopyranoside, kanamycin, and ampicillin were purchased from Research Products International. FMN, FAD, ubiquinone-2, pioglitazone, NL-1, and other chemicals were purchased from Sigma. The molar extinction coefficients of 6.2 mm$^{-1}$cm$^{-1}$ at 340 nm, 12.5 mm$^{-1}$cm$^{-1}$ at 445 nm, and 11.3 mm$^{-1}$cm$^{-1}$ at 450 nm were used for measuring the concentration of NADH/NADPH, FMN, and FAD, respectively (43). The molar extinction coefficient of 14.9 mm$^{-1}$cm$^{-1}$ at 278 nm was used for ubiquinone-2.

Author contributions—Y. W., A. P. L., and H. D. designed, performed, and analyzed the experiments. All authors reviewed the results and approved the final version of the manuscript.
