On the Pontrjagin-Viro Form

Alexander Degtyarev

Abstract. A new invariant, the Pontrjagin-Viro form, of algebraic surfaces is introduced and studied. It is related to various Rokhlin-Guillou-Marin forms and generalizes Mikhalkin’s complex separation. The form is calculated for all real Enriques surfaces for which it is well defined.

Introduction

In this paper we introduce a new invariant, so called Pontrjagin-Viro form, of a real algebraic surface or, more generally, a closed smooth 4n-manifold $X$ with involution $c: X \to X$. The invariant, which is only well defined in certain special cases, is a quadratic function $P: F \to \mathbb{Z}/4$, where $F \subset H_*(\text{Fix}_c; \mathbb{Z}/2)$ is a subgroup of the total homology of the fixed point set of $c$ (or, in the case of an algebraic surface, of the real part of the surface). We mainly concentrate on the case $\dim X = 4$; in this case $P$ turns out to be closely related to the Rokhlin-Guillou-Marin forms (see 2.2) of various characteristic surfaces in $X$ and $X/c$ and, thus, is a direct generalization of the notion of complex separation introduced by G. Mikhalkin [Mik]. (Mikhalkin’s complex separation is defined when $H_1(X; \mathbb{Z}/2) = 0$.) The relation to the Rokhlin-Guillou-Marin form gives a number of congruences which the Pontrjagin-Viro form must satisfy (see 4.2).

This work was mainly inspired by our study of real Enriques surfaces (joint work with I. Itenberg and V. Kharlamov). Recall that an Enriques surface is a complex analytic surface $E$ with $\pi_1(E) = \mathbb{Z}/2$ and $2c_1(E) = 0$. Such a surface is called real if it is supplied with an anti-holomorphic involution $\text{conj}: E \to E$; the fixed point set $E_\mathbb{R} = \text{Fix}_\text{conj}$ is called the real part of $E$. The set of components of the real part of a real Enriques surface naturally splits into two disjoint halves $E^{(1)}_\mathbb{R}, E^{(2)}_\mathbb{R}$ (see 5.1); this splitting is a deformation invariant of pair $(E; \text{conj})$.

The topology of real Enriques surfaces is studied in [DK1] and [DK2], where they are classified up to homeomorphism of the triad $(E_\mathbb{R}; E^{(1)}_\mathbb{R}, E^{(2)}_\mathbb{R})$. Currently, we know the classification up to deformation equivalence (which is the strongest equivalence relation from the topological point of view); a preliminary report is found in [DK3]; details will appear in [DIK]. For a technical reason real Enriques surfaces are divided in [DK3] into three types, hyperbolic, parabolic, and elliptic, according to whether the minimal Euler characteristic of the components of $E_\mathbb{R}$ is negative, zero, or positive, respectively. It turns out that in most cases a real

Key words and phrases. involution on manifold, Enriques surface, real algebraic surface.

An essential part of this work was done during my visits to Université Louis Pasteur, Strasbourg, Université di Trento, and Université de Rennes I.

Typeset by $\LaTeX$
Enriques surface is determined up to deformation equivalence by such classical invariants as the homeomorphism type of the triad \((E_\mathbb{K}; E_\mathbb{K}^{(1)}, E_\mathbb{K}^{(2)})\) and whether the fundamental classes \([E_\mathbb{K}^{(i)}]\) and \([E_\mathbb{K}^{(j)}]\), \(i = 1, 2\), vanish or are characteristic in the homology of \(E\) or some auxiliary manifolds. The few exceptions, mainly \(M\)-surfaces of parabolic and elliptic types, differ by the Pontrjagin-Viro form.

In this paper the Pontrjagin-Viro form is calculated for all real Enriques surfaces for which it is well-defined (see Section 7). There is a necessary condition \((\chi(E_\mathbb{K}) = 0 \mod 8)\) and certain sufficient conditions (Lemma 5.2.1) for \(\mathcal{P}\) to be well defined, and, when defined, \(\mathcal{P}\) must satisfy certain congruences (Proposition 5.2.2) which follow from the general congruences in 4.2. The result of the calculation can be roughly stated as follows (see Theorems 7.1.1, 7.2.1, and 7.3.1 for the precise statements): Consider a triad \((E_\mathbb{K}; E_\mathbb{K}^{(1)}, E_\mathbb{K}^{(2)})\) with \(\chi(E_\mathbb{K}) = 0 \mod 8\). Any (partial) quadratic form \(\mathcal{P}: H_\ast(E_\mathbb{K}^{(1)}) \oplus H_\ast(E_\mathbb{K}^{(2)}) \to \mathbb{Z}/4\) satisfying the congruences of Proposition 5.2.2 can be realized as the Pontrjagin-Viro form of a real Enriques surface. If \((E_\mathbb{K}; E_\mathbb{K}^{(1)}, E_\mathbb{K}^{(2)})\) does not satisfy the sufficient conditions of Lemma 5.2.1, it can also be realized by a real Enriques surface not admitting Pontrjagin-Viro form. Note that, in fact, the deformation type of a surface admitting Pontrjagin-Viro form is determined by the topology of \((E_\mathbb{K}; E_\mathbb{K}^{(1)}, E_\mathbb{K}^{(2)})\) and the isomorphism type of \(\mathcal{P}: H_\ast(E_\mathbb{K}^{(1)}) \oplus H_\ast(E_\mathbb{K}^{(2)}) \to \mathbb{Z}/4\) (see [DIK]).

Originally in order to distinguish nonequivalent real Enriques surfaces we calculated the Pontrjagin-Viro form by explicitly constructing membranes in \(E/\text{conj.\conj.}\). In Section 6 I develop a different approach, which facilitates the calculation and, on the other hand, covers all real Enriques surfaces which are of interest. The approach is applicable to a specific construction (which, as is shown in [DIK], produces all \(M\)-surfaces of elliptic and parabolic types): the surface in question is constructed starting from a pair of real curves \(P, Q\) on a real rational surface \(Z\), and the Pontrjagin-Viro form is given in terms of the topology of their real parts \((Z_\mathbb{R}; P_\mathbb{R}, Q_\mathbb{R})\). The fact that \(\mathcal{P}\) is related to the complex orientation of the branch curve was indicated to me by G. Mikhalkin.

Contents. Section 1 introduces the primary tool, so called Kalinin’s spectral sequence. Section 2 reminds the basic notions related to quadratic forms and Rokhlin-Guillou-Marin form of a characteristic surface. The Pontrjagin-Viro form is introduced in Section 3, and its basic properties, including the congruences, are studied in Section 4. In Section 5 the general results are transferred to real Enriques surfaces. In Section 6 we calculate the Pontrjagin-Viro form of a real Enriques surface obtained by a specific construction, using so called Donaldson’s trick; these results are applied in Section 7 to produce the complete list of possible values of the Pontrjagin-Viro form on a real Enriques surface.

Acknowledgements. I am thankful to I. Itenberg and V. Kharlamov for many hours of fruitful discussions of the subject; the results of this paper depend essentially upon our joint work on real Enriques surfaces. I am also thankful to G. Mikhalkin for his helpful remarks.

Notation. Unless stated otherwise, all homology and cohomology groups are with coefficients in \(\mathbb{Z}/2\). We freely denote by \(2; \mathbb{Z}/2 \to \mathbb{Z}/4\) the nontrivial homomorphism, as well as the induced homomorphisms \(H_\ast(\cdot; \mathbb{Z}/2) \to H_\ast(\cdot; \mathbb{Z}/4)\) etc.

Given a vector bundle \(\xi\), we denote by \(w_i(\xi)\) and \(u_i(\xi)\) the Stiefel-Whitney and Wu classes, respectively. \(w = 1 + w_1 + \ldots\) and \(u = 1 + u_1 + \ldots\) are the corresponding
total classes. If \( X \) is a smooth manifold and \( \tau X \) its tangent bundle, we abbreviate \( w_1(\tau X) = w_1(X) \) and \( u_i(\tau X) = u_i(X) \). For a smooth submanifold \( V \subset X \) we denote by \( \nu V \) its normal bundle in \( X \).

Let \( X \) be a closed manifold of dimension \( n \). Then \( [X] \in H_n(X) \) is its fundamental class and \( \langle X \rangle \in H_0(X) \) is the 0-class defined by the union of points, one in each component of \( X \). (Certainly, the latter definition applies to any polyhedron.) The Poincaré duality \( \cap[X] \): \( H^i(X) \to H_{n-i}(X) \) is denoted by \( D_X = D \).

If \( X \) is a complex manifold, \( c_1(X) \in H_2(X; \mathbb{Z}) \) stand for its Chern classes and \( K_X \), for both the canonical class in \( \text{Pic}(X) \) and its image \( D_X c_1(K_X) \) in \( H_2(X) \) (so that we can write \( [D] = K_X \) for a divisor \( D \)).

1. Kalinin’s spectral sequence

1.1. Basic concepts. Let \( X \) be a good topological space (say, a finite dimensional CW-complex) and \( c: X \to X \) an involution. Unless stated otherwise, we assume \( X \) connected. Denote by \( F \) the fixed point set \( \text{Fix } c \) and by \( \overline{X} \), the orbit space \( X/c \).

Let \( \text{pr}: X \to \overline{X} \) be the projection and in: \( F \hookrightarrow X \) and \( \text{in}: F \to \overline{X} \) the inclusions.

Recall that the Borel-Serre spectral sequences \( ^*E_{p,q} \) and \( ^*E^{p,q} \) are the Serre spectral sequences of the fibration \( S^\infty \times_c X \to \mathbb{R}p^\infty \), where \( S^\infty \times_c X \) is the Borel construction \( S^\infty \times X/(s,x) \sim (-s,cx) \). As shown in [Ka], multiplication by the generator \( h \in H^1(\mathbb{R}p^\infty) \) establishes isomorphisms \( ^*E_{p,q+1} \to ^*E_{p,q} \) and \( ^*E^{p,q} \to ^*E^{p,q+1} \) for \( p \gg 0 \) and thus produces stabilized spectral sequences \( (^H_*, ^d) \) and \( (^H^*, ^d^*) \), which we call Kalinin’s spectral sequences of \((X,c)\), so that

\[
\begin{align*}
(1) \quad ^1H_* &= H_*(X) \quad \text{and} \quad ^1H^* = H^*(X) ,
(2) \quad ^1d_* &= (1 + c_*) \quad \text{and} \quad ^1d^* = (1 + c^*) ,
(3) \quad ^1H_* &\Rightarrow H_*(F) \quad \text{and} \quad ^1H^* \Rightarrow H^*(F) .
\end{align*}
\]

An alternative, geometrical, description of Kalinin’s spectral sequences and related objects is found in [DK2].

The convergence in (3) means that there is an increasing filtration \( \{ F_p \} \) on \( H_*(F) \), a decreasing filtration \( \{ F_p \} \) on \( H^*(F) \), and homomorphisms \( b^p: F_p \to ^\infty H_p \) and \( b^p: ^\infty H^p \to H^*(F)/F_p-1 \) which establish isomorphisms of the graded groups. (Note that in general the filtrations do not respect the grading on \( H_*(F) \) and \( H^*(F) \).) We call \( b^p \) and \( b^p \) the Viro homomorphisms: often they will be considered as additive relations (partial homomorphisms) \( H_*(F) \to H_*(F) \) and \( H^*(X) \to H^*(F) \).

1.2. Multiplicative structures. The homology and cohomology versions of Kalinin’s spectral sequences are dual to each other, i.e., \( ^1H^p = \text{Hom}(^1H_p, \mathbb{Z}/2) \) and \( ^1d^p = \text{Hom}(^1d_p, \mathbb{Z}/2) \). The cup- and cap-products convert \( ^1H^* \) and \( ^1H_* \) to a graded \( \mathbb{Z}/2 \)-algebra and a graded \( ^1H^* \)-module, respectively, so that all the differentials except \( ^1d \) are differentiations. Furthermore, if \( X \) is a closed \( n \)-manifold and \( F \neq \emptyset \), the Poincaré duality \( D_X \) induces isomorphisms \( D: ^1H^p \to ^1H_{n-p} \), and in the usual way one can define intersection pairings \( \ast: ^1H_p \otimes ^1H_q \to ^1H_{p+q-n} \). The induced (via \( b_* \)) pairing on the graded group \( \text{Gr}^*_F H_*(F) \) is called Kalinin’s intersection pairing. The ordinary intersection pairing on \( H_*(F) \) will be denoted by \( \circ \).

1.2.1. Theorem (see [DK2]). Let \( X \) be a smooth closed \( n \)-manifold and \( c: X \to X \) a smooth involution. Then for \( a \in F^p \) and \( b \in F^q \) one has \( w(\nu F) \cap (a \circ b) \in F^{p+q-n} \) and

\[
bv_p a \circ bv_q b = bv_{p+q-n}[w(\nu F) \cap (a \circ b)] .
\]
1.3. Relation to the Smith exact sequence. Recall that the Smith exact sequences of \((X, c)\) are the exact sequences

\[
\rightarrow H_{p+1}(\bar{X}, F) \xrightarrow{\Delta} H_p(\bar{X}, F) \oplus H_p(F) \xrightarrow{pr} H_p(\bar{X}, F) \rightarrow ,
\]

\[
\rightarrow H^p(\bar{X}, F) \xrightarrow{pr^*} H^p(X) \xrightarrow{\iota^*} H^p(\bar{X}, F) \oplus H^p(F) \xrightarrow{\Delta} H^{p+1}(\bar{X}, F) \rightarrow .
\]

The connecting homomorphisms \(\Delta\) are given by \(x \mapsto \omega \cdot x + \partial x\) (in homology) and \(x \oplus f \mapsto \omega \cdot x(x \oplus df)\) (in cohomology), where \(\omega \in H^1(\bar{X} \setminus F)\) is the characteristic class of the double covering \(X \setminus F \rightarrow \bar{X} \setminus F\). In [DK2] it is shown that Kalinin’s spectral sequences can be derived from the Smith exact sequences. In this paper we only need the corresponding description of the differentials and Viro homomorphisms:

1.3.1. Theorem (see [DK2]). The differentials \(^d_p\) and \(^d^p\), considered as additive relations \(H_p(X) \rightarrow H_{p+1}(X)\) and \(H^p(X) \rightarrow H^{p+1}(X)\), are given by

\[
\iota^* d_p = tr \circ (\Delta^{-1} \circ \iota)^{-1} \circ pr, \quad \iota^* d^p = pr^* (\pi \circ \Delta^{-1})^{-1} \circ \pi \circ tr^*,
\]

where \(\iota: H_p(\bar{X}, F) \rightarrow H_p(X, F) \oplus H_p(F)\) and \(\pi: H^p(\bar{X}, F) \oplus H^p(F) \rightarrow H^p(X, F)\) are, respectively, the inclusion and the projection.

A (nonhomogeneous) class \(x = \sum_{i \leq p} x_i\), \(x_i \in H_i(F)\), belongs to \(F^p\) if and only if there are elements \(y_i \in H_i(\bar{X}, F)\) such that \(\Delta(y_{i+1}) = y_i \oplus x_i\) for \(i < p\). In this case \(b_p x = tr \sum_{i < p} (y_i \oplus x_i)\) (modulo the indeterminacy subgroup).

A class \(x \in H^p(X)\) survives to \(\infty H^p\) if and only if \(tr^* x = y^p \oplus x^p\) extends to a sequence \(y^i \oplus x^i \in H^i(\bar{X}, F) \oplus H^i(F)\), \(i \leq p\), such that \(y^{i+1} = \Delta(y^i \oplus x^i)\) for \(i < p\). In this case \(b_p x = \sum_{i \leq p} x^i\) mod \(F^p_{p-1}\).

1.4. Groups \(\mathcal{B}\) and \(\mathcal{Z}\). Let \(\mathcal{B}_p \subset \mathcal{Z}_p \subset H_p(X)\) be the pull-backs of \(\text{Im} \pi^{-1}d_p\) and \(\text{Ker} \pi^{-1}d_p\), respectively, so that \(H_p = \mathcal{B}_p / \mathcal{Z}_p\). Denote \(\infty \mathcal{B}_p = \bigcup r^p \mathcal{B}_p\) and \(\infty \mathcal{Z}_p = \bigcap r^p \mathcal{Z}_p\). Then \(\infty H_p = \mathcal{Z}_p / \infty \mathcal{B}_p\). There are obvious cohomology analogues \(\infty \mathcal{B}^p \subset \mathcal{Z}^p \subset H^p(X)\), and \(\infty H^p = \mathcal{Z}^p / \infty \mathcal{B}^p\) for \(1 \leq p \leq \infty\).

1.4.1. Proposition. One has \(\infty \mathcal{Z}_p = \text{Ker} [pr_+: H_p(X) \rightarrow H_p(\bar{X}, F)]\) and \(\infty \mathcal{B}^p = \text{Im} [pr^*: H^p(X, F) \rightarrow H^p(X)]\).

Proof. The statement follows from Theorem 1.3.1. Since all the spaces involved are finite dimensional, both the Smith exact sequences terminate. Hence, an element \(x \in H_p(X)\) is annihilated by all \(d_p\), \(p > 0\), if and only if \((\pi \circ pr_+)(x) = 0\). Similarly, for any element \(x \in H^p(\bar{X}, F)\), the multiple image \((\Delta^r)^{-1}(x)\) belongs to \(\text{Im} (\pi \circ tr^*)\) for \(r \gg 0\).

1.4.2. Corollary. If \(X\) is a closed smooth manifold, \(c\) is a smooth involution, and \(F \neq \emptyset\), then \(\infty \mathcal{B}_* = \text{Im} [tr_+: H_*(\bar{X} \setminus F) \rightarrow H_*(X)]\) and \(\infty \mathcal{Z}_* = \text{Ker} [tr^*: H^*(X) \rightarrow H^*(\bar{X} \setminus F)]\).

Proof. This follows from 1.4.1 and Poincaré duality.

1.5. Miscellaneous statements. In this section we state several simple results needed in the sequel.

1.5.1. Proposition (see [DK2]). Denote by \(\text{Sq}_1\) the homology Bockstein homomorphism. Then for any class \(x = \sum_{i \leq p} x_i \in F^p, x_i \in H_i(F)\), one has

\[
\text{Sq}_1 b_p x = b_{p-1} (\text{Sq}_1 x + \sum_{i} ix_i) = b_{p-1} (\text{Sq}_1 x + \sum_{i}(i + 1)x_i).
\]

(In particular, the classes in parentheses belong to \(F^{p-1}\).)
2.1. Proposition. Let $X$ be an oriented closed smooth $n$-manifold, $H_1(X) = 0$, and $B \subset X$ a $c$-invariant oriented closed smooth submanifold of pure codimension 2 such that $[B] = 0$ in $H_{n-2}(X)$. Assume that $c$ reverses the co-orientation of $B$. Let further, $p : Y \to X$ be the (unique) double covering of $X$ branched over $B$ and $\omega_p$ its characteristic class. Then for $x \in H_1(F \setminus B)$ one has $\langle \omega_p, x \rangle = b v_2 x \circ \frac{1}{2}[B]$ (where $\frac{1}{2}[B]$ is obtained by dividing by 2 the integral class $[B] \in H_{n-2}(X; \mathbb{Z})$).

Proof. Realize $x$ by an oriented simple loop $I$. After multiplying it by an odd integer we may assume that $I$ bounds an oriented membrane $\mathcal{M}$ in $X$, which may be chosen transversal to $B$. Then $\langle \omega_p, x \rangle = \text{Card}(\mathcal{M} \cap B) \mod 2$. On the other hand, $\text{Card}(\mathcal{M} \cap B) = b v_2 x$ and the statement follows from $\text{Card}(\mathcal{M} \cap B) = \frac{1}{2}[\mathcal{M} \cup c(\mathcal{M})] \circ [B]$. (Note that $c$ reverses the orientation of $\mathcal{M}$.) \ \qed

2.1.3. Proposition. Assume that $X$ is a closed 4-manifold, $H_1(X; \mathbb{Z}) = 0$, and $F$ is a surface. Then $\tilde{X}$ is a $\mathbb{Z}$-homology 4-sphere if and only if $c$ is an $M$-involution (i.e., $\dim H_*(F) = \dim H_*(\tilde{X})$) and $F$ is connected. If this is the case, $c_*$ acts as multiplication by $(-1)$ on $H_2(X; \mathbb{Z})$.

Proof. Assume that $F \neq \emptyset$ (as otherwise $H_1(\tilde{X}) = \mathbb{Z}/2$). Then $H_1(\tilde{X}; \mathbb{Z}) = 0$ and the first statement follows from comparing the Euler characteristics using the Riemann-Hurwitz formula. For the second statement observe that $H_*(\tilde{X}; \mathbb{Q})$ is the $c_*$-invariant part of $H_*(X; \mathbb{Q})$; this determines the action of $c_*$ on $H_*(X; \mathbb{Z}) \subset H_*(X; \mathbb{Q})$. \ \qed

2. Rokhlin-Guillou-Marin congruence

2.1. Quadratic forms and Brown invariant. The results of this section should be found in most textbooks in arithmetic; see also [vdB], [Br], [GM], or [KV].

Let $V$ be a $\mathbb{Z}/2$-vector space and $\circ : V \otimes V \to \mathbb{Z}/2$ a symmetric bilinear form. A function $q : V \to \mathbb{Z}/4$ is called a quadratic extension of $\circ$ if $q(x + y) = q(x) + q(y) + 2(x \circ y)$ for all $x, y \in V$. The pair $(V, q)$ is called a quadratic space. (Obviously, $\circ$ is recovered from $q$.) A quadratic space is called nonsingular if the bilinear form is nonsingular, i.e., $V^\perp = \emptyset$; it is called informative if $q|_{V^\perp} = 0$. The following is straightforward:

2.1.1. Proposition. Let $V$ be a $\mathbb{Z}/2$-vector space and $\circ : V \otimes V \to \mathbb{Z}/2$ a symmetric bilinear form. Then

1. $q(x) \equiv x^2 \mod 2$ for any $x \in V$ and any quadratic extension $q$ of $\circ$;
2. quadratic extensions of $\circ$ form an affine space over $V^\circ = \text{Hom}(V, \mathbb{Z}/2)$ via $(q+l)(x) = q(x) + 2l(x)$ for $l \in V^\circ$ and $x \in V$;
3. if $\circ$ is nonsingular, its quadratic extensions form an affine space over $V$ via $(q+v)(x) = q(x) + 2(v \circ x)$ for $v, x \in V$.

The Brown invariant $\text{Br}(V, q)$ (or just $\text{Br} q$) of a nonsingular quadratic space is the (mod 8)-residue defined by

$$\exp \left( \frac{i}{2} \pi \text{Br} q \right) = 2^{\frac{1}{2} \dim V} \sum_{x \in V} \exp \left( \frac{i}{2} \pi q(x) \right).$$

This notion extends to informative spaces: since $q$ vanishes on $V^\perp$, it descends to a quadratic form $q^\prime : V/V^\perp \to \mathbb{Z}/4$, and one lets $\text{Br} q = \text{Br} q^\prime$. 
2.1.2. Proposition. For any informative quadratic space \((V, q)\) one has:

1. \(\text{Br} q \equiv \dim(V/V^+) \mod 2\);
2. \(\text{Br} q \equiv q(u) \mod 4\) for any characteristic element \(u \in V\);
3. \(\text{Br}(q + v) = \text{Br} q - 2q(v)\) for any \(v \in V\) (see 2.1.1(3));
4. \(\text{Br} q = 0\) if and only if \((V, q)\) is null cobordant, i.e., there is a subspace \(H \subset V\) such that \(H^\perp = H\) and \(q|_H = 0\).

The Brown invariant is additive: for any pair \((V_i, q_i), i = 1, 2\), of quadratic spaces one has \(\text{Br}(V_1 \oplus V_2, q_1 \oplus q_2) = \text{Br}(V_1, q_1) + \text{Br}(V_2, q_2)\).

2.1.3. Proposition. Let \(L\) be a unimodular integral lattice (i.e., a free abelian group with a nonsingular symmetric bilinear form \(L \otimes L \to \mathbb{Z}\)). Let \(V = L \otimes \mathbb{Z}/2\) and define a quadratic form \(q: V \to \mathbb{Z}/4\) via \(q(x) = \tilde{x}^2 \mod 4\) for \(x \in V\) and \(\tilde{x} \in L\) such that \(\tilde{x} \equiv x \mod 2L\). Then \(\text{Br}(V, q) \equiv \sigma(L) \mod 8\).

A subspace \(W\) of an informative quadratic space \((V, q)\) is called informative if \(W^\perp \subset W\) and \(q|_{W^\perp} = 0\). (Clearly, an informative subspace is an informative space; hence, its Brown invariant is well defined.)

2.1.4. Proposition. If \(W\) is an informative subspace of an informative quadratic space \((V, q)\), then \(\text{Br}(W, q|_W) = \text{Br}(V, q)\).

Remark. The notion of informative subspace still makes sense if the quadratic form \(q\) is defined only on \(W\). Proposition 2.1.4 can then be interpreted as follows: the Brown invariant of any extension of \(q\) to a quadratic form on \(V\) equals \(\text{Br} q\).

2.2. Rokhlin-Guillou-Marin congruence (see [GM]). Let \(Y\) be an oriented closed smooth 4-manifold and \(U\) a characteristic surface in \(Y\), i.e., a smooth closed 2-submanifold (not necessarily orientable) with \([U] = u_2(Y)\) in \(H_2(Y)\). Denote by \(i: U \hookrightarrow Y\) the inclusion and let \(K = \text{Ker}\{i_*: H_1(U) \to H_1(Y)\}\). Then there is a natural function \(q: K \to \mathbb{Z}/4\), which is a quadratic extension of the intersection index form on \(H_1(U)\). We call it the Rokhlin-Guillou-Marin form of \((Y, U)\). It can be defined as follows: pick a class \(x \in K\) and realize it by a union of disjoint simple closed smooth loops in \(U\). It spans an immersed surface \(\mathcal{M}\) in \(Y\), which can be chosen normal to \(U\) along \(\partial \mathcal{M}\) and transversal to \(U\) at its inner points. (Such a surface is called a membrane.) Consider a normal line field \(\xi\) on \(U\) tangent to \(U\) and define the index \(\text{ind}\mathcal{M} \in \frac{1}{2}\mathbb{Z}\) as one half of the obstruction to extending \(\xi\) to a normal line field on \(\mathcal{M}\). (Since \(\tau\mathcal{M} \oplus \nu\mathcal{M}\) is an oriented vector bundle, the obstruction is well defined as an integer. If \(\xi\) is two-sided in \(U\), the index is usually defined using vector fields instead of line fields; this explains the factor \(\frac{1}{2}\).) Then \(q(x) = 2\text{ind}\mathcal{M} + 2\text{Card}(\text{int}\mathcal{M} \cap F) \mod 4\).

2.2.1. Theorem (see [GM]). Let \(Y, U,\) and \((K, q)\) be as above. Then \((K, q)\) is an informative subspace of \(H_1(U)\) and \(2\text{Br} q = \sigma(Y) - U \circ U \mod 16\), where \(U \circ U\) stands for the normal Euler number of \(U\) in \(Y\).

Remark. There is an alternative construction of the Rokhlin-Guillou-Marin form. Since \(U\) is characteristic, \(Y \setminus U\) admits a Spin-structure which does not extend through any component of \(U\). Its restriction to the boundary of a tubular neighborhood of \(U\) induces in a natural way a Pin\(^-\)-structure on \(U\) (cf. [Fin]), which defines a quadratic form \(q\) on \(H_1(U)\). It is not difficult to see that \(q\) is well defined up to adding elements of \(\text{Im}[i^*: H^1(U) \to H^1(U)]\) (see 2.1.1(2)) and, hence, its restriction to \(K\) does not depend on the choice of a Spin-structure; it coincides with \(q\).
3. Pontrjagin-Viro form

3.1. Definition of the Pontrjagin-Viro form. The Pontrjagin square is the cohomology operation \( P^{2n} : H^{2n}(X) \to H^{4n}(X; \mathbb{Z}/4) \) uniquely defined by the following properties (see, e.g., [EM]):

1. \( P^{2n}(x + y) = P^{2n}(x) + P^{2n}(y) + 2(x \cup y) \) for any \( x, y \in H^{2n}(X) \);
2. \( P^{2n}(x) \equiv x^2 \mod 2 \) for any \( x \in H^{2n}(X) \);
3. \( P^{2n}(\bar{x} \mod 2) = \bar{x}^2 \) for any \( \bar{x} \in H^{2n}(X; \mathbb{Z}/4) \).

Constructively \( P^{2n} \) can be defined via \( P^{2n}(x) = (\bar{x} \cup_0 \bar{x} + \bar{x} \cup_1 \delta\bar{x}) \mod 4 \), where \( \bar{x} \in C^{2n}(X; \mathbb{Z}) \) is an integral cochain representing \( x \) and \( \cup_i \) are the cup-\( i \)-products used in one of the definition of Steenrod squares.

From now on we assume that \( X \) is a connected oriented closed smooth manifold of dimension \( 4n \) and \( c \) is a smooth involution. Denote by \( P_{2n} : H_n(X) \to \mathbb{Z}/4 \) the composition

\[
H_{2n}(X) \xrightarrow{D^X_2} H^{2n}(X) \xrightarrow{P^{2n}} H^{4n}(X; \mathbb{Z}/4) \xrightarrow{\cap[x]} \mathbb{Z}/4.
\]

3.1.1. Proposition-Definition. If \( P_{2n}(\bar{B}_{2n}) = 0 \), then \( P_{2n} \) descends to a well-defined quadratic function \( \bar{H}_{2n} \to \mathbb{Z}/4 \). The composition of this function and the Viro homomorphism \( \nu_{2n} : F^{2n} \to \bar{H}_{2n} \) is denoted by \( \mathcal{P} \) and is called the Pontrjagin-Viro form. It is a quadratic extension of Kalinin’s intersection form \( *: F^{2n} \otimes F^{2n} \to \mathbb{Z}/2 \), i.e., \( \mathcal{P}(x + y) = \mathcal{P}(x) + \mathcal{P}(y) + 2(x \ast y) \) for any \( x, y \in F^{2n} \).

Proof. The statement follows immediately from the fact that \( \bar{B}_n \circ \bar{Z}_n = 0 \) (where \( \circ \) stands for the intersection pairing and property 3.1(1) above).

3.1.2. Proposition. \( \mathcal{P} \) is well defined if and only if \( u_{2n}(\bar{X} \setminus F) = 0 \).

Proof. The statement is a consequence of Corollary 1.4.2 and the obvious relation \( P_{2n}(\text{tr}_* x) = 2(x \circ x) = 2(u_{2n}(\bar{X} \setminus F), x) \) for \( x \in H_{2n}(\bar{X} \setminus F) \). The latter follows from properties 3.1(1) and (2) of Pontrjagin squares and the fact that \( \text{tr}_* \), when restricted to the manifold \( \bar{X} \setminus F \), coincides with the inverse Hopf homomorphism \( \nu^1 \).

3.1.3. Corollary. Assume that \( F \) has pure dimension \( \dim X - 2 \), so that \( \bar{X} \) is a manifold. Then \( \mathcal{P} \) is well defined if and only if \( D_{\bar{X}} u_{2n}(\bar{X}) \) belongs to the image of \( \bar{m}_*: H_{2n}(F) \to H_{2n}(\bar{X}) \).

3.1.4. Proposition. If \( \mathcal{P} \) is well defined, \( \text{Br} \mathcal{P} \equiv \sigma(X) \mod 8 \).

Proof. By definition, \( \mathcal{P} \) is well defined if and only if \( \bar{Z}_{2n} \) is an informative subspace of \( (H_{2n}(X), P_{2n}) \). (Due to the Poincaré duality \( \bar{Z}_k \cong \bar{B}_{2n} \), see [DK2].) Hence, \( \text{Br} \mathcal{P} = \text{Br} P_{2n} \). On the other hand, \( H_{2n}(X; \mathbb{Z}) \otimes \mathbb{Z}/2 \) is also an informative subspace, and the congruence follows from Proposition 2.1.3 applied to \( H_{2n}(X; \mathbb{Z})/\text{Tors} \).

3.2. Some sufficient conditions.

3.2.1. Proposition. Let \( c \) be orientation preserving. Then \( P_{2n} \) descends to \( 2H_{2n} \) if and only if the \( 2n \)-dimensional component of \( \text{im}((u(\tau F)u^{-1}(\nu_X F)) \) equals \( u_{2n}(X) \).

Proof. As known, the \( 2n \)-dimensional component of \( \text{im}((u(\tau F)u^{-1}(\nu_X F)) \) coincides with the characteristic class \( \theta_{2n} \) of the twisted intersection form \( \langle x, y \rangle \mapsto x \circ c_y \) (see, e.g., [CM]). On the other hand, for \( x \in H_{2n}(X) \) one has

\[
P_{2n}(1d_{2n} x) = P_{2n}(x + c_x) = 2P_{2n}(x) + 2(x \circ c_x) = 2(\theta_{2n} + u_{2n}, x)
\]

(since \( P_{2n}(x) \equiv x^2 \mod 2 \)), and the statement follows.
3.2.2. Corollary. A necessary condition for $\mathcal{P}$ to be well defined is that $\theta_{2n}$, the $2n$-dimensional component of $\text{im}(u(\tau F)u^{-1}(v_X F))$, must coincide with $u_{2n}(X)$. The following are sufficient conditions:

1. $c$ is an $M$-involution (i.e., $d_* = 0$ for $r \geq 1$);
2. $\theta_{2n} = u_{2n}(X)$ and $c$ is $\mathbb{Z}/2$-Galois maximal (i.e., $d_* = 0$ for $r \geq 2$);
3. $\theta_{2n} = u_{2n}(X)$ and $H_i(X) = 0$ for $0 < i < 2n$.

Remark. If $\dim F \leq 2n$, the condition of 3.2.1 (and, hence, the necessary condition of 3.2.2) reduces to $[F]_{2n} = Du_{2n}(X)$ in $H_{2n}(X)$, where $[F]_{2n}$ is the fundamental class of the union of $2n$-dimensional components of $F$. In this case 3.2.1 can be proved using the following observation:

3.2.3. Proposition (V. Arnol’d). If $\dim X = 2k$ is even and $\dim F \leq k$, then the fundamental class $[F]_k$ of the union of $k$-dimensional components of $F$ realizes in $H_k(X)$ the characteristic class of the twisted intersection form $(x, y) \mapsto x \circ c_* y$.

Remark. If $\dim X = 4$ and $F$ is a surface, 3.2.1 follows also from the projection formula $D_X u_2(X) = \text{tr}_2 D_X u_2(\bar{X}) + [F]$: since $D_X u_2(\bar{X})$ comes from $F$, its pull-back in $X$ is zero.

3.3. Membranes. The first statement, which is a direct consequence of the definitions, calculates the Pontrjagin square in a 4-manifold.

3.3.1. Lemma. Let $X$ be an oriented closed smooth 4-manifold and $\mathcal{M} \rightarrow X$ an immersed closed surface. Then $P_2[\mathcal{M}] = \mathcal{M} \circ \mathcal{M} + 2\chi(\mathcal{M})$ mod 4, where $\mathcal{M} \circ \mathcal{M} = e(\mu \mathcal{M}) + 2i$ mod 4 is the normal Euler number of $\mathcal{M}$ plus twice the number of its self-intersection points mod 4. (If $\mathcal{M}$ is oriented, $\mathcal{M} \circ \mathcal{M} = [\mathcal{M}]_2^2$ mod 4, where $[\mathcal{M}]_2 \in H_2(X; \mathbb{Z})$ is the integral class realized by $\mathcal{M}$.)

Next two statements provide for geometrical means of calculating $b_{v_2}$ and, hence, the Pontrjagin-Viro form in a 4-manifold.

3.3.2. Lemma. Let $\mathcal{M}$ be a closed surface with involution $c$ so that $\text{Fix} c$ consists of several two-sided circles $l_1, \ldots, l_p$, several one-sided circles $n_1, \ldots, n_q$, and several simple isolated points $P_1, \ldots, P_r$. Then $[\mathcal{M}] = b_{v_2} \varkappa$, where

$$\varkappa = \sum [l_i] + \sum [n_j] + \sum [P_k] + \sum (m_i).$$

Proof. Without loss of generality we may assume that $\mathcal{M}$ is connected. Then, due to 3.2.3, $b_{v_1}(\sum [l_i] + \sum [n_j])$ equals $w_1(\mathcal{M})$ in $\infty H_1$; hence, $q \equiv \dim H_*(\mathcal{M})$ mod 2. Due to the Smith congruence $\chi(\text{Fix} c) \equiv \chi(\mathcal{M})$ mod 2, also $r \equiv \dim H_*\mathcal{M}$ mod 2. Thus, $b_{v_0} \varkappa = 0$ and $b_{v_1} \varkappa$ is well defined. Now one can easily check that $b_{v_1} \varkappa$ annihilates $\infty H_1$ (which is generated by the images under $b_{v_1}$ of $[l_i], [n_j]$, and elements of the form $\langle Q_1 - Q_2 \rangle$, $Q_1, Q_2 \in \text{Fix} c$). Since Kalinin’s intersection form is nondegenerate, $b_{v_1} \varkappa = 0$. Hence, $b_{v_2} \varkappa$ is well defined, and it must coincide with the only nontrivial element $[\mathcal{M}] \in \infty H_2$. □
3.3.3. Corollary. Let $\mathcal{M}$ and $\tau$ be as in 3.3.2. If $\mathcal{M}$ is equivariantly immersed to a topological space $X$ with involution, then $[\mathcal{M}]$ realizes $b_{v_2} \tau$. If, further, $\dim X = 4$ and $\mathcal{P}$ is well defined, then $\mathcal{P}(\tau) = [\mathcal{M}] \circ \mathcal{M} + 2\chi(\mathcal{M}) \mod 4$.

4. Congruences

4.1. Characteristic surfaces in $\bar{X}$. Let us assume that $X$ is an oriented closed smooth 4-manifold, $c: X \to X$ is a smooth orientation preserving involution, and $F = \text{Fix} c \neq \emptyset$ has pure dimension 2. Under these assumptions $\bar{X}$ is also an oriented closed manifold.

We keep the notation introduced in Section 1. In addition, denote by $\mathcal{F}_p$ and $\bar{\mathcal{F}}_p$, respectively, the intersection $\mathcal{F}_p \cap H_i(F)$ and the projection of $\mathcal{F}_p$ to $H_i(F)$. Recall that the connecting homomorphism $\Delta$ of the homology Smith exact sequence is given by $y \mapsto \omega \cap y \oplus \partial y$, where $\omega \in H^1(\bar{X} \setminus F)$ is the characteristic class of the covering $X \setminus F \to \bar{X} \setminus F$. Since the covering $X \to \bar{X}$ is branched along $F$, one has $\partial \bar{X} \omega = [F]$.

4.1.1. Lemma. $b_{v_2} \mathcal{F}_0 = \text{tr}_* H_2(\bar{X}) \mod \infty B_2$. Furthermore, for $y \in H_2(\bar{X})$ one has $\text{tr}_* y = b_{v_2}(\bar{m}^1 y) \mod \infty B_2$; in particular, $\mathcal{P}(\bar{m}^1 y) = 2y_2^2 \mod 4$ provided that $\mathcal{P}$ is well defined.

Proof. As follows from 1.3.1, the image $b_{v_2} \mathcal{F}_0$ consists of all elements of the form $\text{tr}_* y_2$, where $y_2 \in H_2(\bar{X}, F)$ extends to a sequence $y_i \in H_i(\bar{X}, F)$, $i = 0, 1, 2$, such that $\Delta(y_2) = y_1$ and $\Delta(y_1) = y_0 \oplus x_0$ for some $x_0 \in H_0(F)$. Thus, $y_1$ may be an arbitrary element, and the only restriction to $y_2$ is $\partial y_2 = 0$, i.e., $y_2 = \text{rel} y$ for some $y \in H_2(\bar{X})$. For the ‘furthermore’ part observe that $\text{tr}_* y = \text{tr}_* y_2 = b_{v_2} x_0$ and

$$x_0 = \partial(\omega \cap \text{rel} y) = \partial(D \omega \cap D^{-1} y) = [F] \cap \bar{m}^* D^{-1} y = D F \bar{m}^* D^{-1} y = \bar{m}^1 y,$$

where $D = D_{\bar{X}}$. □

4.1.2. Lemma. $b_{v_1} \mathcal{F}_1 = \text{tr}_* H_1(\bar{X}, F) \mod \infty B_1$.

4.1.3. Lemma. $\bar{F}_1 = \text{Ker}[\bar{m} \circ H_1(F) \to H_1(\bar{X})]$.

Proof of 4.1.2 and 4.1.3. As above, the statements follow directly from 1.3.1. □

4.1.4. Corollary. $\text{Ker}[\bar{m} \circ H_2(F) \to H_2(\bar{X})]$ is the annihilator of $\mathcal{F}_0$ with respect to the intersection index pairing $H_2(F) \otimes H_0(F) \to \mathbb{Z}/2$ (or, equivalently, Kalinin’s intersection pairing $H_2(F) \otimes \bar{\mathcal{F}}_0 \to \mathbb{Z}/2$).

Proof. Let $K = \text{Ker}[\bar{m} \circ H_2(F) \to H_2(\bar{X})]$. Since the restrictions of the ordinary intersection index pairing and Kalinin’s intersection pairing to $H_2(F) \otimes \bar{\mathcal{F}}_0$ coincide (see 1.2.1), it suffices to verify that $u \in K$ if and only if $b_{v_2} u$ annihilates $b_{v_2} \mathcal{F}_0 = \text{tr}_* H_2(\bar{X}) \in \infty H_2$. For $y \in H_2(\bar{X})$ one has $\bar{m} \circ \text{tr}_* y = \bar{m} \circ u \circ y$; this product vanishes for all $y \in H_2(\bar{X})$ if and only if $\bar{m} \circ u = 0$. □

4.1.5. Corollary. Assume that $\mathcal{P}$ is well defined. Then an element $u \in H_2(F)$ realizes $Du_2(\bar{X})$ if and only if $\mathcal{P}(x) = 2(u \circ x) \mod 4$ for all $x \in \mathcal{F}_0$.

4.2. Pontrjagin-Viro form and Rokhlin-Guillou-Marin forms. We still assume that $X$ is an oriented closed smooth 4-manifold, $c$ is smooth and orientation preserving, and $F \neq \emptyset$ has pure dimension 2. Assume also that $\mathcal{P}$ is well defined; due to 3.1.3 this implies that $u_2(\bar{X})$ is realized by a union of components of $F$. 
4.2.1. Proposition. Let $F' \subset F$ be a union of components of $F$ such that $\mathcal{P}(x) = 2([F'] \circ x) \mod 4$ for all $x \in F_0^2$. Let $H' = H_1(F') \cap F_0^2$ and define a quadratic function $\mathcal{P}' : H' \to \mathbb{Z}/4$ via $x_1 \mapsto \mathcal{P}(x_1 + x_0) + 2([F'] \circ x_0)$, where $x_0 \in H_0(F)$ is any element such that $x_1 + x_0 \in F^2$. Then $\mathcal{P}'$ coincides with the Rokhlin-Guillou-Marin form $q'$ of the characteristic surface $F'$ in $X$. In particular, $(H', \mathcal{P}')$ is an informative subspace of $H_1(F')$.

Proof. First notice that $q'$ is well defined and, due to 4.1.3, its domain coincides with that of $q$. Pick an element $x \in H'$ and consider a membrane $\mathcal{M}$ as in 2.2. Let $\mathcal{M}' = \text{pr}^{-1} \mathcal{M}$; it is a closed $c$-invariant surface in $X$. The index $\text{ind} \mathcal{M}$ (see 2.2) equals the normal Euler number $\mathcal{M}$. The intersection points of int $\mathcal{M}$ and $F$ correspond to isolated fixed points of $c|\mathcal{M}'$, and all the 1-dimensional components of $\text{Fix} c|\mathcal{M}'$ are two-sided in $\mathcal{M}'$. The statement follows now from comparing the definitions of $q'$ and $q^*$ and Lemma 3.3.3. (Note that the total number of intersection points of int $\mathcal{M}$ and $F$ is even and, hence, so is $\chi(\mathcal{M}')$.) \hfill \Box

4.2.2. Theorem. If $F'$ and $\mathcal{P}'$ are as in 4.2.1, then

$$F' \circ F' + \text{Br} \mathcal{P}' = \frac{1}{4}[F \circ F + \sigma(X)] \mod 8.$$ 

Proof. The statement follows from Proposition 4.2.1, Theorem 2.2.1 applied to $F' \subset X$, and the well known calculation of the ingredients of 2.2.1: the self-intersection numbers of $F'$ in X and $\tilde{X}$ are related via $(F' \circ F')_{\tilde{X}} = 2(F' \circ F')_X$, and the signature of $\tilde{X}$ is given by the Hirzebruch formula $\sigma(X) = 2\sigma(X) - F \circ F$. \hfill \Box

4.2.3. Theorem. The restriction $\mathcal{P}_{[1]}$ of $\mathcal{P}$ to $F_0^2$ coincides with the Rokhlin-Guillou-Marin form $q$ of the characteristic surface $F$ in $X$. In particular, $(F_0^2, \mathcal{P}_{[1]})$ is an informative subspace of $H_1(F)$ and

$$F \circ F + 2\text{Br} \mathcal{P}_{[1]} \equiv \sigma(X) \mod 16.$$ 

Proof. The two forms are compared as in the previous proof: $q$ is calculated via a generic membrane $\mathcal{M}$ as in 2.2 and $\mathcal{P}_{[1]}$, via $\mathcal{M}' = \mathcal{M} \cup c(\mathcal{M})$. We may assume that $\mathcal{M}'$ is an immersed surface. It realizes bv$_2(\partial \mathcal{M}')$, as all the components of $\partial \mathcal{M}'$ are two-sided in $\mathcal{M}'$ and the intersection points of int $\mathcal{M} \cap F$ are not fixed points of the lift of $c$ to the normalization of $\mathcal{M}'$. Note also that the self-intersection points of $\mathcal{M}'$ which are not on $F$ appear in pairs and thus do not contribute to $\mathcal{M}' \circ \mathcal{M}'$. \hfill \Box

Remark. Let $X$ be the complexification of a real algebraic surface and $c = \text{conj}$ the Galois involution on $X$. (More generally, one can assume that $X$ is a compact smooth complex analytic surface and $c$ is an anti-holomorphic involution.) Then $\text{Fix} \ c = X_{\mathbb{R}}$ is the real part of $X$ and multiplication by $\sqrt{-1}$ establishes an isomorphism $\tau X_{\mathbb{R}} = \nu X_{\mathbb{R}}$. In particular, for any component $F_i$ of $X_{\mathbb{R}}$ one has $F_i \circ F_i = -\chi(F_i)$, and the congruences of 4.2.2 and 4.2.3 take the form

\begin{align*}
(4.2.4) \quad & \chi(F') \equiv \frac{1}{4}[\chi(X_{\mathbb{R}}) - \sigma(X)] + \text{Br} \mathcal{P}' \mod 8, \\
(4.2.5) \quad & \chi(X_{\mathbb{R}}) \equiv 2\text{Br} \mathcal{P}_{[1]} - \sigma(X) \mod 16.
\end{align*}
Since $\chi(F') \equiv BrP' \text{ mod } 2$, (4.2.4) implies

\[(4.2.6) \quad \chi(X_R) \equiv \sigma(X) \text{ mod } 8.\]

(Certainly, (4.2.6) follows as well from the Arnol’d congruence for real algebraic surfaces with $|X_R| = D_Xu_2(X)$ in $H_2(X)$.)

5. **Real Enriques surfaces**

5.1. **Real Enriques surfaces.** Recall that an algebraic surface $X$ is called a $K3$-surface if $\pi_1(X) = 0$ and $c_1(X) = 0$. An algebraic surface $E$ is called an *Enriques surface* if $\pi_1(E) = \mathbb{Z}/2$ and the universal covering $X$ of $E$ is a $K3$-surface. (The classical definition of Enriques surfaces is $c_1(E) \neq 0$, $2c_1(E) = 0$, and the relation to $K3$-surfaces follows from the standard classification.) All $K3$-surfaces form a single deformation family; they are all diffeomorphic to a degree 4 surface in $\mathbb{P}^3$. Similarly, all Enriques surfaces form a single deformation family and are all diffeomorphic to each other. The intersection forms of $K3$- and Enriques surfaces are, respectively, $H_2(X; \mathbb{Z}) \cong 3E_8 \oplus 2U$ and $H_2(E; \mathbb{Z}) \cong E_8 \oplus U$, where $E_8$ is the even unimodular form of signature $-8$ and $U$ is the hyperbolic plane.

A real *Enriques surface* is an Enriques surface $E$ supplied with an anti-holomorphic involution $\text{conj}: E \rightarrow E$, called *real structure*. The fixed point set $E_R = \text{Fix conj}$ is called the *real part* of $E$. (Obviously, these definitions apply to any algebraic variety.)

Fix a real Enriques surface $E$ and denote by $p: X \rightarrow E$ its universal covering and by $\tau: X \rightarrow X$, the *Enriques involution* (i.e., deck translation of $p$). The real structure $\text{conj}$ on $E$ lifts to two real structures $t^{(1)}, t^{(2)}: X \rightarrow X$, which commute with each other and with $\tau$. Let $X^{(i)}_R = \text{Fix } t^{(i)}$, $i = 1, 2$, be their real parts. The projections $E^{(i)}_R = p(X^{(i)}_R)$ are called *halves* of $E_R$. It is easy to see that $E^{(1)}_R$ and $E^{(2)}_R$ are disjoint, $E_R = E^{(1)}_R \cup E^{(2)}_R$, and both $E^{(i)}_R$ consist of whole components of $E_R$. Furthermore, two components $F_1, F_2 \subset E_R$ belong to the same half if and only if $b\nu_1(F_1 - F_2) = 0$ (see [DK2]).

A real Enriques surface is said to be of of *hyperbolic, parabolic, or elliptic type* if the minimal Euler characteristic of the components of $E_R$ is negative, zero, or positive, respectively.

5.2. **The Pontrjagin-Viro form on a real Enriques surface.** Fix a real Enriques surface $E$. For the topological types of the connected components of $E_R$ we will use the notation $S = S^2$, $S_p = \#_p(S^3 \times S^1)$, and $V_p = \#_p\mathbb{R}P^2$. The decomposition of $E_R$ into two halves will be designated via $E_R = \{E^{(1)}_R\} \cup \{E^{(2)}_R\}$.

$E$ is said to be of *type I* if $[E_R] = 0$ in $(H_2(E; \mathbb{Z})/\text{Tors}) \otimes \mathbb{Z}/2$ or, equivalently, $[X^{(1)}_R] + [X^{(2)}_R] = 0$ in $H_2(X)$; otherwise $E$ is said to be of *type II*. Type I is further subdivided into $I_0$ and $I_0$ depending on whether $|E_R| = 0$ or $Du_2(E) \in H_2(E)$.

5.2.1. **Lemma.** The following are sufficient conditions for the existence of the Pontrjagin-Viro form $\mathcal{P}: F^2 \rightarrow \mathbb{Z}/4$ on a real Enriques surface $E$:

1. $E$ is an $M$-surface;
2. $E$ is of type $I_0$ and either $E_R$ is nonorientable or both $E^{(1)}_R$ and $E^{(2)}_R$ are nonempty;
3. $E$ is of type $I$, $E_R$ is nonorientable, and either both $E^{(1)}_R$ and $E^{(2)}_R$ are nonempty or $E_R$ contains a nonorientable component of odd genus.
Proof. As shown in [DK2], the subgroup $F^2 \subset H_*(E_\mathbb{R})$ is generated by elements of the form $[F_0]$ and $\langle F_1 - F_2 \rangle \oplus x_1$, where $F_0$, $F_1$, $F_2$ are components of $E_\mathbb{R}$, $x_1 \in H_1(E_\mathbb{R})$, and either $x_1^2 = 1$ and $F_1$, $F_2$ are in distinct halves, or $x_1^2 = 0$ and $F_1$, $F_2$ are in the same half. In particular, $E$ is Galois maximal if and only if $E_\mathbb{R}$ is nonorientable or both $E^{(1)}_\mathbb{R}$, $E^{(2)}_\mathbb{R}$ are nonempty. If $E$ satisfies the hypotheses of (3), then $Du_q(E) \neq 0$ in $\infty H_2$. Since $[E_\mathbb{R}] = Du_q(E)$ in $\infty H_2$, type I implies $I_u$. All the statements follow now from Corollary 3.2.2. □

From now on we assume that $P$ is defined. Two components $F_1$, $F_2$ of the same half are said to be in one quoter if $P(F_1 - F_2) = 0$. Since $P$ is linear on $F^2_\mathbb{R}$, each half $E^{(i)}_\mathbb{R}$ splits into two quoters, which consist of whole components of $E^{(i)}_\mathbb{R}$. We denote this by $E^{(i)}_\mathbb{R} = (quoter 1) \cup (quoter 2)$. Following [Mik], the decomposition of $E_\mathbb{R}$ into four quoters is called complex separation. Due to 4.1.5 it has the following geometrical meaning: a subsurface $F' \subset E_\mathbb{R}$ is characteristic in $E/\text{conj}$ if and only if it is the union of two quoters which belong to distinct halves.

Let $E_\mathbb{R} = \{(Q^{(1)}_i) \cup (Q^{(2)}_j) \cup \{(Q^{(1)}_j) \cup (Q^{(2)}_i)\}$ be the decomposition of $E_\mathbb{R}$ into quoters. If both the halves are nonempty, denote by $q^{(1)}_i$ and $q^{(2)}_j$ the restriction to $H_1(Q^{(1)}_i)$ (respectively, $H_1(Q^{(2)}_j)$) of the Rokhlin-Guillou-Marin form of the characteristic surface $Q^{(1)}_i \cup Q^{(2)}_j$. As follows from 4.2.1,

$$\begin{align*}
q^{(1)}_{i_1} &= q^{(1)}_{i_2} + Dw_1(Q^{(1)}_i) \quad \text{and, hence,} \quad Br q^{(1)}_{i_1} = -Br q^{(1)}_{i_2}, \\
q^{(2)}_{j_1} &= q^{(2)}_{j_2} + Dw_1(Q^{(2)}_j) \quad \text{and, hence,} \quad Br q^{(2)}_{j_1} = -Br q^{(2)}_{j_2}
\end{align*}$$

(see 2.1.2 and 2.1.1). If one of the halves, say, $E^{(2)}_\mathbb{R}$, is empty, denote by $q^{(1)}_i$ the restriction of $P$ to $H_2(Q^{(1)}_i)$; this form is defined on the annihilator of $w_1(Q^{(1)}_i)$ and is informative. In this notation congruence (4.2.4) takes the following form:

5.2.2. Proposition. If both the halves are nonempty, then for $i, j = 1, 2$

$$\chi(Q^{(1)}_i) + \chi(Q^{(2)}_j) \equiv 2 + \frac{1}{4} \chi(E_\mathbb{R}) + Br q^{(1)}_{ij} + Br q^{(2)}_{ji} \mod 8$$

If $E^{(2)}_\mathbb{R} = \emptyset$, then for $i = 1, 2$

$$\chi(Q^{(1)}_i) \equiv 2 + \frac{1}{4} \chi(E_\mathbb{R}) + Br q^{(1)}_{i} \mod 8.$$  

Another invariant used in the classification is the value $P(w_1)$, where $w_1$ is the characteristic class of a nonorientable component of $E_\mathbb{R}$ of even Euler characteristic.

5.2.3. Proposition. Let $F_1, F_2 \subset E_\mathbb{R}$ be two nonorientable components of even Euler characteristic. Then $P(w_1(F_1)) = P(w_1(F_2))$.

Proof. As shown in [DK1], if $E_\mathbb{R}$ has two nonorientable components of even Euler characteristic, it has no other nonorientable components. Hence, $w_1(E_\mathbb{R}) = w_1(F_1) + w_1(F_2)$. On the other hand, $w_1(E_\mathbb{R})$ is a characteristic element in $F^2$ and, due to 2.1.2(2) and 3.1.4, $P(w_1(E_\mathbb{R})) = 0$. □

6. The Pontrjagin-Viro form via Donaldson’s trick

6.1. Constructing surfaces via Donaldson’s trick. Let $Z$ be a rational surface with real structure $c: Z \rightarrow Z$ and nonempty real part, and $P,Q \subset Z$ a pair of nonsingular real curves.
6.1.1. Assumption. In this and next sections we assume that
(1) \([P]\) and \([Q]\) are even in \(H_2(Z;\mathbb{Z})\) and \([P] + [Q] = -2K_Z\);
(2) \(\dim \ker[\text{inclusion}_*: H_2(P) \to H_2(Z)] = 1\);
(3) the multiplicity of each intersection point of \(P\) and \(Q\) is at most 2.

Since \([P]\) is even, \(P_\mathbb{R}\) divides \(Z_\mathbb{R}\) into two parts with common boundary \(P_\mathbb{R}\). Denote their closures by \(Z^\pm_P = Z^\pm\). Similarly, introduce two parts \(Z^\pm_Q\) with common boundary \(Q_\mathbb{R}\). Let \(Z^{\delta \varepsilon} = Z^\delta_P \cap Z^\varepsilon_Q\) for \(\delta, \varepsilon = \pm\) and assume that
(4) \(Z^{++} = \emptyset\), i.e., \(P_\mathbb{R} \subset Z^{-Q}\) and \(Q_\mathbb{R} \subset Z^{-P}\).

Consider the double covering \(Y \to Z\) branched over \(P\) and denote by \(B\) the pull-back of \(Q\). Let \(Y'\) be the minimal resolution of singularities of \(B\) (which occur at the tangency points of \(P\) and \(Q\) and are all nondegenerate double points) and \(B'\) the proper transform of \(B\). The real structure \(c\) on \(Z\) lifts to two real structures \(c^\pm\) on \(Y'\). In respect to one of them, \(c^+\), the real part \(Y'_R\) projects to \(Z^+\) and \(B'_R = \emptyset\).

6.1.2. Proposition. \(Y\) and \(Y'\) are rational surfaces, \([B] = -2K_Y\), and \([B'] = -2K_{Y'}\). The double covering \(X \to Y'\) of \(Y'\) branched over \(B'\) is a \(K3\)-surface.

Proof. The relations \([B] = -2K_Y\) and \([B'] = -2K_{Y'}\) follow from the projection formula and 6.1.1(1). Thus, the anti-bicanonical class of \(Y\) is effective and, hence, \(Y\) is either rational or ruled. On the other hand, from the Smith exact sequence and (2) it follows that \(H_1(Y') = 0\). Hence, \(Y\) is rational. Now the projection formula gives \(2K_X = 0\), i.e., \(X\) is a minimal surface of Kodaira dimension 0. Using the Riemann-Hurwitz and adjunction formulas one obtains \(\chi(X) = 2\chi(Y') + 2K_Y^2 = 24\). Hence, \(X\) is a \(K3\)-surface.

Denote by \(t^{(1)}\) the deck translation of \(X \to Y'\). Due to (4) above one of the two lifts of \(c^+\) to \(X\) is fixed point free; denote it by \(\tau\). One can now apply to \((t^{(1)}, \tau)\) the following equivariant version of Donaldson’s trick:

6.1.3. Proposition (cf. [DK3]). Let \(X\) be a \(K3\)-surface and \((c_h, c_a)\) a pair of commuting involutions on \(X\), one holomorphic and one anti-holomorphic. Then there is a complex structure on \(X\) in respect to which \(c_h\) is anti-holomorphic and \(c_a\) is holomorphic.

Let \(\tilde{X}\) be the resulting \(K3\)-surface. Then the quotient \(E = \tilde{X}/\tau\) is an Enriques surface and \(t^{(1)}\) descends to a real structure \(\rho\) on \(E\). Clearly, \(E^{(1)}_R = B'/c^+\) and \(E^{(2)}_R = Y'_R\), and there is a projection \(\pi: E_R \to \tilde{Q} \cup Z^+\), which is a branched double covering outside the tangency points of \(P_R\) and \(Q_R\). The pull-back \(\pi^{-1}(T)\) of each tangency point \(T\) consists of a one-sided loop in \(E^{(2)}_R\) and a point in \(E^{(1)}_R\). Let \(\rho\): \(E_R \to E\) be the deck translation of \(\pi\).

6.1.4. Notation. For a subset \(S \subset \tilde{Q} \cup Z^+\) we denote by \((\pi^{-1}(Q)) \in H_0(E_R)\) the class generated by the connected components of \(\pi^{-1}(S)\), and by \([\pi^{-1}(S)] \in H_c(E_R)\), the fundamental class of its components of highest dimension (provided that they are all closed manifolds).

6.2. Existence of \(P\) and complex separation. Let \(E\) be a real Enriques surface obtained as in 6.1 from a configuration \((Z; P, Q)\). For all intermediate objects we keep the notation introduced in 6.1.

A nonsingular real curve \(C \subset Z\) is said to be of type I, or separating, if \(C/c\) is orientable. The real part of each real component \(C_i\) of \(C\) has a distinguished
pair of opposite orientations, called complex orientations, which are induced from an orientation of $C_i/c$. The complement $C_i \setminus C_{i,R}$ consists of two components $C^\pm_i$ with common boundary $C_{i,R}$; their natural orientations induce the two complex orientations of $C_{i,R}$.

A triple $(Z; P, Q)$ as in 6.1 is said to be of type I if $P$ is of type I and $Z^{-} \setminus Q_R$ is orientable. Let $P_i, i = 1, \ldots, p$, and $Q_j, j = 1, \ldots, q$, be the real components of the curves, $Z^-_k, k = 1, \ldots, z^-$, the connected components of $Z^{-} + Z^{-}$, and $Z^+_l, l = 1, \ldots, z^+$, the connected components of $Z^+$. Fix some orientations of $Z^{-}_k$ and some complex orientations of $P_{i,R}$; this determines an orientation of $P_i$ and a distinguished half $P_i^+$ for each real component $P_i$. Thus, the fundamental classes $[P_i]$ and $[Z^-_k]$ are well defined mod 4 in all homology groups where they make sense. The classes $[Q_j]$ and $[Z^+_l]$ are defined mod 2.

6.2.1. Definition. We say that a triple $(Z; P, Q)$ of type I admits a fundamental cycle if there are some odd integers $\lambda_i, i = 1, \ldots, p$, and $\kappa^{-}_k, k = 1, \ldots, z^-$, and some integers $\mu_j, j = 1, \ldots, q$, and $\kappa^{+}_l, l = 1, \ldots, z^+$ such that

\[
(6.2.2) \quad \sum \lambda_i [P_{i,R}] + \sum \kappa^{-}_k [\partial Z^-_k] = 2 \sum \mu_j [Q_{j,R}] + 2 \sum \kappa^{+}_l [\partial Z^+_l]
\]

in $H_1(P_R \cup Q_R; \mathbb{Z}/4)$. The combination

\[
(6.2.3) \quad \mathcal{C} = \sum \lambda_i [\bar{P}_i] + \sum \kappa^{-}_k [Z^-_k] + 2 \sum \mu_j [\bar{Q}_j] + 2 \sum \kappa^{+}_l [Z^+_l],
\]

which is a (mod 4)-cycle in $Z$, is called a fundamental cycle. It is called proper if $[\mathcal{C}] = 2Dw_2(Z)$ in $H_2(Z; \mathbb{Z}/4)$.

6.2.4. Proposition. A triple $(Z; P, Q)$ of type I admits a fundamental cycle if and only if $\sum [P_{i,R}]$ belongs to the subgroup in $H_1(Z^{-}; \mathbb{Z}/4)$ spanned by the classes $2[P_{i,R}], 2[Q_{j,R}],$ and $2[\partial Z^+_l]$. If $Z$ is an $M$-surface with $Z_R$ connected, any fundamental cycle is proper.

Proof. The first part follows from the exact sequence of pair $(Z^{-}, P_R \cup Q_R)$. If $Z$ is an $M$-surface with $Z_R$ connected, then $\bar{Z}$ is a $Z$-homology sphere (see 1.5.3) and $[\mathcal{C}] = 2w_2(\bar{Z})$ holds trivially. □

The Pontrjagin-Viro form on a real Enriques surface $E$ is said to have $\rho$-invariant complex separation if all quoters are fixed by $\rho$. Since $P$ is obviously $\rho_+$-invariant, for each half $E^{-}_i, i = 1, 2$, one has either $\rho(Q^{(i)}_j) = Q^{(i)}_j$, $j = 1, 2$, or $\rho(Q^{(i)}_j) = Q^{(j)}_i$. This remark is sufficient to eliminate the possibility of noninvariant complex separation in all cases considered in Section 7 below.

6.2.5. Theorem. The real Enriques surface resulting from a triple $(Z; P, Q)$ has Pontrjagin-Viro form with $\rho$-invariant complex separation if and only if all tangency points of $P$ and $Q$ are real and $(Z; P, Q)$ is of type I and admits a proper fundamental cycle. If this is the case, the complex separation is determined by a proper fundamental cycle $(6.2.3)$:

1. the components $\pi^{-1}(Q_a), \pi^{-1}(Q_b)$ corresponding to real components $Q_a, Q_b$ of $Q$ belong to the same quoter if and only if $\mu_a - \mu_b \equiv 0 \mod 2$;
2. the components $\pi^{-1}(Z^+_a), \pi^{-1}(Z^+_b)$ corresponding to $Z^+_a, Z^+_b \subset Z^+$ belong to the same quoter if and only if $\kappa^+_a - \kappa^+_b \equiv 0 \mod 2$. 

6.2.6. Corollary. A proper fundamental cycle (6.2.3) is unique mod 4 up to \(2[Z_R]\) and \(2(Z^+ + \{P\})\), and \(2(Z^- + \{Q\})\).

6.3. Proof of Theorem 6.2.5. Note that the construction of 6.1 still works if 6.1.1(1) and (2) are replaced with a weaker assumption

\((1')\) \([P]\) and \([Q]\) are divisible by 2 in \(H_2(Z; \mathbb{Z})\).

Certainly, Proposition 6.1.2 does not hold in this case and 6.1.3 does not apply; thus, \(E\) is just a 4-manifold with orientation preserving involution. In view of 3.1.3 Theorem 6.2.5 would follow from the following more general result:

6.3.1. Theorem. Let \((E, \text{conj})\) be the manifold with involution resulting from a triple \((Z; P, Q)\) satisfying \((1')\) above and 6.1.1(3), (4). Then \(E_R \subset E/\text{conj}\) contains a \(\rho\)-invariant characteristic surface if and only if all tangency points of \(P\) and \(Q\) are real and \((Z; P, Q)\) is of type I and admits a proper fundamental cycle. If this is the case, the \(\rho\)-invariant characteristic subsurfaces of \(E_R\) are those of the form \(\sum \mu_j \pi^{-1}(\bar{Q}_j) + \sum \kappa_i^\rho[Z_i^\rho]\), where \(\mu_j\) and \(\kappa_i^\rho\) are the coefficients of a proper fundamental cycle.

In order to prove Theorem 6.3.1 we replace \(E/\text{conj}\) with \(\bar{Y}' = Y'/c^+\). In the construction \(Y'\) is obtained from \(Y\) by blow-ups of the tangency points of \(P\) and \(Q\). If such a point is real, the blow-up results in connected summation of \(Y\) and \(\overline{C^{p}/\text{conjugation}} \cong S^4\) and thus does not affect the topology. A pair of conjugate tangent points results in the (topological) blow-up of their common image in \(\bar{Y}\). This produces a \((-1)\)-sphere in \(\bar{Y}'\) which is (mod 2)-orthogonal to all pull-backs \([\pi^{-1}(\bar{P}_j)]\) and \([\pi^{-1}(\bar{Z}_i^+)]\), which shows that \(E_R\) does not contain a \(\rho\)-invariant characteristic surface. Thus, we can assume that \(P\) and \(Q\) do not have imaginary tangency points and replace \(\bar{Y}'\) with \(\bar{Y}\).

Clearly, \(\bar{Y}\) is the double covering of \(\bar{Z} = Z/c\) branched over the Arnol'd surface \(A^- = \bar{P} \cup Z^-\). Denote by \(pr: \bar{Y} \to \bar{Z}\) the projection and by \(\omega \in H^1(\bar{Z} \setminus A^-)\) its characteristic class. Since \(pr: H_3(\bar{Z}, A^-) \to H_3(A^-)\) is a monomorphism, \(\omega\) is uniquely characterized by the property \(\partial D\omega = [A^-]\). Note also that, since \(\bar{Z}\) is orientable, \(\omega \cap D\omega = Sq_1 \cdot D\omega \in H_2(\bar{Z}, A^-)\) and \(\partial Sq_1 \cdot D\omega = Sq_1[A^-] = Dw_1(A^-)\).

6.3.2. Lemma. \(\sum \mu_j \pi^{-1}(\bar{Q}_j) + \sum \kappa_i^\rho[Z_i^\rho] = Dw_2(\bar{Y})\) in \(H_2(\bar{Y})\) if and only if in \(H_2(\bar{Z}, A^-)\)

\[\sum \mu_j \bar{Q}_j + \sum \kappa_i^\rho[Z_i^\rho] = Sq_1 \cdot Dw + Dw_2(\bar{Z}).\]  

Proof. The statement follows immediately from the projection formula and Smith exact sequence. \(\square\)

6.3.4. Lemma. A linear combination (6.2.3) is a fundamental cycle if and only if \(\sum \mu_j \partial \bar{Q}_j + \sum \kappa_i^\rho[\partial Z_i^\rho] = Dw_1(A^-)\) in \(H_1(A^-)\).

Proof. This is a direct consequence of the definition of Bockstein homomorphism via chains. \(\square\)

From Lemma 6.3.4 it follows that a necessary condition for (6.3.3) to hold is that \(\mu_j, \kappa_i^\rho\) must be coefficients of a fundamental cycle; in particular, this implies that \((\bar{Z}, P, Q)\) must be of type I. If this is the case, \(\text{Sq}_1 \cdot D\omega\) is the relativization of a class \(x \in H_2(\bar{Z}, \bar{P}_R \cup \bar{Q}_R)\), which is well defined up to the image of \(H_2(A^-)\) and has the property \(2x = \sum \bar{P}_j + \sum [Z_k^-] \mod 2H_2(A^-)\) in \(H_2(\bar{Z}, \bar{P}_R \cup \bar{Q}_R; Z/4)\). Since
both $\times 2$: $H_2(\tilde{\mathcal{Z}}, \tilde{\mathcal{P}}_R \cup \tilde{\mathcal{Q}}_R) \rightarrow H_2(\tilde{\mathcal{Z}}, \tilde{\mathcal{P}}_R \cup \tilde{\mathcal{Q}}_R; \mathbb{Z}/4)$ and relativization $H_2(\tilde{\mathcal{Z}}; \mathbb{Z}/4) \rightarrow H_2(\tilde{\mathcal{Z}}, \tilde{\mathcal{P}}_R \cup \tilde{\mathcal{Q}}_R; \mathbb{Z}/4)$ are monomorphisms, (6.3.3) is equivalent to the fact that $\mu_j$ and $\nu_j$ are coefficients of a proper fundamental cycle. \[\square\]

6.4. Values on 1-dimensional classes. Fix a triple $(Z; P, Q)$ satisfying the conditions of Theorem 6.2.5, so that the Pontrjagin-Viro form $\mathcal{P}$ on $E$ is well defined and the complex separation is $\rho$-invariant.

Denote $\mathcal{S} = Z_R \cup \hat{P} \cup \hat{Q}$ and for an immersed (in the obvious sense) loop $I \subset \mathcal{S}$ transversal to $P_R$ and $Q_R$ define its ‘normal Euler number’ $e(I) \in \mathbb{Z}/2$ to be 1 or 0 mod 2 depending on whether $I$ is disorienting or not. (If $I$ passes through an isolated intersection point of $\hat{P}$ and $\hat{Q}$, the orientation is transferred so that the point have intersection index +1.) The following obvious observation is helpful in evaluating $e(I)$: let an oriented arc $I'$ belong to a half $C^+$ of a type I curve $C$ (which, in our case, can be union of real components of $P$ and separating real components of $Q$) so that $\partial I' \subset C_R$ and $I'$ is normal to $C_R$. Then the co-orientation induced from the complex orientation of $C_R$ at the initial point of $I'$ is transferred by $I'$ to the co-orientation opposite to the complex orientation of $C_R$ at the terminal point of $I'$.

6.4.1. Proposition. For $I \subset \mathcal{S}$ as above one has

$$\mathcal{P}([\pi^{-1}(I)] \oplus \pi^{-1}(I)) = 2e(I) + 2i_Q(I) + 2i^+(I) + i_{P \cap Q}(I) \mod 4,$$

where $i_Q(I)$ and $i^+(I)$ are the numbers of isolated intersection points of $I$ with $\hat{Q}$ and $Z^+$, respectively, and $i_{P \cap Q}(I)$ is the number of intersection points $\hat{P} \cap \hat{Q}$ through which $I$ passes.

Proof. Let $\mathcal{M}$ be a membrane in $\tilde{Z}$ normal along $\partial \mathcal{M} = I$ and transversal in int $\mathcal{M}$ to all strata of $\mathcal{S}$. Then the value in question can be found using $\mathcal{M}_Y = pr^{-1}(\mathcal{M})$ (cf. 4.2.1). Clearly, $\text{ind } \mathcal{M}_Y = 2 \text{ind } \mathcal{M} + \frac{1}{2} i_{P \cap Q}(I)$. (To define $\text{ind } \mathcal{M}$, we use a normal line field on $I$ tangent to all strata of $\mathcal{S}$ and patch it at the points of $\hat{P} \cap \hat{Q}$ using local orientations.) Further, $\text{Card}(\text{int } \mathcal{M}_Y \cap E_R^{(1)}) = i_Q(I) + 2 \text{Card}(\text{int } \mathcal{M} \cap \hat{Q})$ and $\text{Card}(\text{int } \mathcal{M}_Y \cap E_R^{(2)}) = i^+(I) + 2 \text{Card}(\text{int } \mathcal{M} \cap Z^+)$. It remains to notice that $2 \text{ind } \mathcal{M} = 0$ or 1 mod 2 depending on whether the line field is orientable or not. \[\square\]

6.4.2. Proposition. For a point $T \in P_R \cap Q_R$ one has $\mathcal{P}([\pi^{-1}(T)] + (\pi^{-1}(T))) = 1$.

Let $S$ be a connected component of one of $\hat{Q}$, $\hat{P}$, or $Z_R \setminus (P_R \cup Q_R)$. Assume that $\partial S$ does not contain a tangency point of $P$ and $Q$. Then $\partial S$ is a loop in $E_R$.

6.4.3. Proposition. Let $Z^-_k$ be a connected component of $Z^-$ with $\partial Z^-_k$ disjoint from $P_R \cap Q_R$. Then $\mathcal{P}[\partial Z^-_k] = 2\chi(Z^-_k) \mod 4$.

6.4.4. Proposition. Let $P_i$ be a real component of $P$ with $P_i \cap Q_R$ disjoint from $P_R \cap Q_R$. Then $\mathcal{P}([Z_i] + (\pi^{-1}(\hat{P}_i \cap \hat{Q}))) = \frac{1}{2} |P_i|^2 \mod 4$.

Proof of Propositions 6.4.2, 6.4.3, and 6.4.2. We lift $Z^-_k$ (respectively, $P_i$ or the exceptional curve appearing when $T$ is blown up in $Y$) to $X$ and then project the result to $E$. This gives a coni-invariant closed surface in $E$, and the value in question is found via 3.3.3. \[\square\]

In the rest of this section we consider the case when $S$ is either $\hat{Q}_j$ for a real component $Q_j$ of $Q$ or a component $Z^+_i$ of $Z^+$. Fix a proper fundamental cycle $\mathcal{C}$
and denote by $U$ the corresponding characteristic surface in $\tilde{Y}$. Assume that $U$
 contains $\pi^{-1}(S) \subset E_{\mathbb{R}}$ and denote by $q_E$ the Rokhlin-Guillou-Marin form of $U$. The choice of $C$ determines a preferred orientation of $\tilde{P}$ (which induces $\sum \lambda_i [P_i, S]$ mod 4 on $\partial \tilde{P}$) or, equivalently, a half $P^+$ of $P \setminus \partial P$.

Let $\omega \in H^1(\mathbb{Z}_{2})$ be the class Poincaré dual to $[C_2]$, where $C \subset Z$ is a real curve with $2[C] = [P]$ in $H_2(Z; \mathbb{Z})$. The restriction of $\omega$ to $Z_R \setminus P_R$ is the characteristic class of the restricted covering $Y \to Z$ (see 1.5.2). For each real component $Q_j$ of $Q$ denote by $\omega_j \in H^1(\hat{Q}_j \setminus \hat{P})$ the characteristic class of the covering $\hat{Y} \to \hat{Z}$ restricted to $\hat{Q}_j \setminus \hat{P}$. ($\omega_j$ can be interpreted as the linking number with $\mathbb{A}^-$ in $\hat{Z}$.)

Assume that $\langle \omega, [\tilde{\partial}S] \rangle = 0$ for each boundary component $\tilde{1} \subset \tilde{S}$ and define the ‘linking number’ $\text{lk}_S w_1(S) \in \mathbb{Z}/4$ of the characteristic class of $S$ with the Arnold surface. Fix some orientations of the boundary components and, if $S = Q_j$, some local orientations at the intersection points $S \cap \tilde{P}$. This defines a lift of $w_1(S)$ to a class $w'_j \in H^1(S, \partial S \cup (S \cap \tilde{P}))$ (which can be defined as the obstruction to extending the chosen orientations to the whole surface). We let $\text{lk}_S w_1(S) = 2\langle \omega, Dw'_j \rangle$ if $S = Z_i^+$ or $2\langle \omega_j, Dw'_j \rangle - \langle \text{int} S \circ \tilde{P} \rangle$ if $S = Q_j$. (In the latter case the intersection index is defined mod 4 using the chosen local orientations of $S$; the condition $\langle \omega_j, [\text{int} \tilde{S}] \rangle = 0$ implies that $\partial S$ is not linked with $\mathbb{A}^-$ and, hence, $\text{int} S \circ \tilde{P} = 0$ mod 2.)

In the case $S = \tilde{Q}_j$ for a real component $Q_j$ of $Q$ the above definition is cumbersome and not ‘seen’ in the real part. If $Q_j$ is of type I, it can be simplified: $\text{lk}_S w_1(S) = \text{Card}(Q_j^+ \cap P^+) - \text{Card}(Q_j^+ \cap P^-)$ mod 4 for any half $Q_j^+$ of $Q_j$.

**6.4.5. Proposition.** Let $S$ be either $\tilde{Q}_j$ for a real component $Q_j$ of $Q$, or a component $Z_i^+$ of $Z^+$. Assume that $\text{lk}_S$ is disjoint from $P_R \cap Q_R$ and $\langle \omega, [\tilde{\partial}S] \rangle = 0$ for each boundary component $\tilde{1} \subset \tilde{S}$. Then $q_E[\tilde{\partial}S] = \text{lk}_S w_1(S)$.

**Remark.** Proposition 6.4.5 applies to the generalized construction described in 6.3. In the case of Enriques surfaces, due to Corollary 6.2.6, the preferred orientation of $\tilde{P}$ is defined up to total reversing and $\text{lk}_S w_1(S)$ does not depend on the choice of $C$. Furthermore, due to the assumption made $\partial S$ is a collection of two-sided circles in $E_{\mathbb{R}}$. Hence, $q_E[\tilde{\partial}S] = \partial S$.

**Proof.** Let $\mathcal{M}_Y \subset \tilde{Y}$ be an oriented membrane normal along $\partial \mathcal{M}_Y = \partial S$ and transversal in $\text{int} \mathcal{M}$ to both $U$ and $\mathbb{A}^-$. Let $\mathcal{M}$ be its projection to $\hat{Z}$. Clearly, $\text{ind} \mathcal{M}_Y = \text{ind} \mathcal{M}$ and the intersection points of $\text{int} \mathcal{M}_Y$ and $U$ project one-to-one. Furthermore, $\mathcal{M}$ is tangent to $\mathbb{A}^-$ at its inner points; hence,

$$2 \text{Card}(\text{int} \mathcal{M}_Y \cap U) = (\text{int} \mathcal{M} \circ \mathcal{C}) - 2(\text{int} \mathcal{M} \circ \mathbb{A}^-) \mod 4.$$

(Recall that $U$ consists precisely of those components of $E_{\mathbb{R}}$ whose coefficients in $\mathcal{C}$ are 2 mod 4.) Since $[\mathcal{C}] = 2w_2(\tilde{Z}) \mod 4$ and $[\mathbb{A}^-] = 0 \mod 2$ in $\tilde{Z}$, the expressions $2 \text{ind} \mathcal{M} + (\text{int} \mathcal{M} \circ \mathcal{C}) \mod 4$ and $(\text{int} \mathcal{M} \circ \mathbb{A}^-) \mod 2$ do not depend on the choice of $\mathcal{M}$; one can replace $\mathcal{M}$ with another membrane, which does not have to lift to $\tilde{Y}$. (Strictly speaking, to claim this one should fix the orientation of $\partial \mathcal{M}$ induced from $\mathcal{M}$; however, it is chosen arbitrarily for $\mathcal{M}_Y$ and does not affect the result.)

Take for a new membrane $S$ shifted along a normal vector field. To make it orientable, fix some choices used to define $\text{lk}_S w_1(S)$, cut $S$ along a simple loop $I$ representing $w'_j$, pick a generic orientable membrane $\mathcal{M}$ spanned by $I$, and attach $2\mathcal{M}$ to the cut. Let $\mathcal{M}$ be the result. Then $\text{int} \mathcal{M} \circ \mathbb{A}^- = \text{Card}(S \cap \tilde{P}) \mod 2$ and

$$\text{int} \mathcal{M} \circ \mathcal{C} = 2 \text{ind} S + (\text{int} S \circ \mathbb{A}^-) + 2 \text{Card}(\mathcal{M} \cap \mathbb{A}^-) \mod 4.$$
(The first term here is due to the original shift of $S$ along a normal field; recall that
$S$ has coefficient 2 mod 4 in $\mathcal{C}$. The second term stands for the intersection index
of $P$ and the cut of $S$, which are both oriented.) Since $\text{ind} \mathcal{M} = \text{ind} S$ mod 2, one obtains $\eta_\mathcal{E}(\partial S) = 2 \text{Card}(\mathcal{M} \cap \mathcal{A}^-) - (\text{int } S \circ \tilde{P}) = \text{lk}_\mathcal{E} w_1(S)$ mod 4. \hfill $\Box$

6.5. Resolving singularities of $P$ and $Q$. Let $(Z'; P', Q')$ be a triple satisfying
6.1.1(1)–(4), except that $P'$ and $Q'$ may be singular. Assume that the curve $P'+Q'$
has at most simple singular points (i.e., those of type $A_p$, $D_q$, $E_6$, $E_7$, or $E_8$).
Then there is a sequence of blow-ups which converts $(Z'; P', Q')$ to a triple $(Z; P, Q)$ with
$P$ and $Q$ nonsingular and satisfying 6.1.1(1)–(4). More precisely, the singularities
of $P'+Q'$ can be resolved by blowing up double or triple points. Let $O$ be a singular
point of, say, $P'$. Blow it up and denote by $e$ the exceptional divisor and by $\tilde{P}$,
the proper transform of $P'$. Then the new pair $(P, Q)$ on the resulting surface is
constructed as follows: $Q$ is the full transform of $Q'$ and $P$ is either $\tilde{P}$ or $P + e$,
depending on whether $O$ is a double or triple point of $P'$. The singular points of $Q'$
are resolved similarly, with $P'$ and $Q'$ interchanged. If the resulting curves $(P, Q)$
are still singular, the procedure is repeated.

7. Calculation for real Enriques surfaces

7.1. $M$-surfaces of elliptic and parabolic type.

7.1.1. Theorem (see [DIK]). A real Enriques $M$-surface $E$ of parabolic or elliptic
type is determined up to deformation equivalence by its complex separation and the
value $P(w_1)$ of $P$ on the characteristic element of a nonorientable component of $E_R$
of even Euler characteristic (if such a component exists). The deformation types
of such surfaces are given in Tables 1 and 2, which list the separations of the two
halves and the possible values of $P(w_1)$.

Remark. In [Kã] it is shown that in all cases listed in the tables $P$ is uniquely
recovered (up to autohomeomorphism of $E_R$ preserving the complex separation)
from the complex separation and $P(w_1)$ via 5.2.2 and, moreover, all forms satisfying
the congruences of 5.2.2 are realized by real Enriques surfaces.

Table 1. $M$-surfaces of elliptic type ($E_R = 4V_1 \cup 2S$)

| $(2V_1 \cup S) \cup (2V_1 \cup S)$ | $\emptyset$ | $(V_1 \cup S) \cup (S)$ | $(2V_1) \cup (V_1)$ |
| $(4V_1) \cup (2S)$ | $\emptyset$ | $(V_1) \cup (2S)$ | $(2V_1) \cup (V_1)$ |
| $(2V_1 \cup S) \cup (V_1 \cup S)$ | $(V_1)$ | $(3V_1) \cup (S)$ | $(V_1) \cup (S)$ |
| $(3V_1) \cup (2S)$ | $(V_1)$ | $(2V_1) \cup (V_1 \cup S)$ | $(V_1) \cup (S)$ |
| $(2V_1 \cup S) \cup (S)$ | $(V_1) \cup (V_1)$ | $(2V_1) \cup (V_1 \cup S)$ | $(V_1 \cup S)$ |
| $(V_1 \cup S) \cup (V_1 \cup S)$ | $(V_1 \cup (V_1)$ | $(2V_1) \cup (2S)$ | $(V_1) \cup (S)$ |
| $(2V_1) \cup (2S)$ | $(V_1) \cup (V_1)$ | $(V_1 \cup S) \cup (S)$ | $(V_1) \cup (V_1)$ |
| $(V_1 \cup S) \cup (V_1 \cup S)$ | $(2V_1)$ | $(V_1 \cup S) \cup (V_1)$ | $(2V_1) \cup (S)$ |
| $(2V_1) \cup (2S)$ | $(2V_1)$ | $(V_1 \cup S) \cup (V_1)$ | $(2V_1) \cup (S)$ |
| $(3V_1) \cup (V_1 \cup S)$ | $(S)$ | $(2V_1) \cup (2V_1)$ | $(2V_1)$ |
| $(3V_1) \cup (2S)$ | $(S)$ | $(2S)$ | $(2V_1)$ |

The calculation of Pontrjagin-Viro forms is based on the results of Section 5 and
the following statement, which gives explicit models of $M$-surfaces of elliptic and
parabolic types:
Table 2. $M$-surfaces of parabolic type

| Case $E_R = S_1 \sqcup V_2 \sqcup 4S$ | Case $E_R = 2V_2 \sqcup 4S$ (continued) |

7.1.2. Theorem (see [DIK]). Up to deformation any real Enriques $M$-surface of parabolic or elliptic type can be obtained by the construction of 6.1 and 6.5 from a triple $(Z'; P', Q')$, where either

1. $Z' = \mathbb{R}^2$, $P'$ is an $M$-curve of degree 4, and $Q'$ is a pair of lines, or
2. $Z'$ is a hyperboloid $\mathbb{R}p^1 \times \mathbb{R}p^1$, $P'$ is a nonsingular $M$-curve of bi-degree $(4, 2)$, and $Q'$ is a pair of generatrices of bi-degree $(0, 1)$.

Figure 1 illustrates the construction of the four nonequivalent surfaces with $E_R = \{2V_2 \sqcup 4S\}$ (see Table 2). To emphasize the difference the linear components of $Q'$ (the lines) are shown tangent to $P'$; in reality they must be shifted away from $P'$.

7.2. $M$-surfaces of hyperbolic type.

7.2.1. Theorem (see [DK3]). A real Enriques surface of hyperbolic type is determined up to deformation by the decomposition $E_R = \{E_R^{(1)}\} \sqcup \{E_R^{(2)}\}$. The realized decompositions are listed in Table 3.

As one can easily see, the Pontrjagin-Viro form of an $M$-surface of hyperbolic type is uniquely recovered from (5.2.2). The corresponding complex separations and values $P(w_1)$ are given in Table 3.

7.3. Other surfaces with Pontrjagin-Viro form.

7.3.1. Theorem. Nonmaximal real Enriques surfaces admitting Pontrjagin-Viro form are those and only those listed in Table 4. The Pontrjagin-Viro form of such a surface is determined, via (5.2.2), by the decomposition $E_R = \{E_R^{(1)}\} \sqcup \{E_R^{(2)}\}$. Table 4 lists the complex separations and values $P(w_1)$ on the characteristic class of a nonorientable component of even genus, if such a component is present. A $^*$ marks the decompositions which are also realized by a real Enriques surface of type II; a

** marks the decompositions which are also realized by a real Enriques surface of type I not admitting Pontrjagin-Viro form.

Proof of Theorem 7.3.1 is based upon the classification of real Enriques surfaces, which will appear in full in [DIK] (see also [DK1]–[DK3]). The necessary partial results are cited below.

The fact that in all cases listed in Table 4 the Pontrjagin-Viro form is determined by (5.2.2) is straightforward. Thus, it remains to enumerate the surfaces for which the Pontrjagin-Viro form is well defined. In view of (4.2.6) for such a surface \(E\) one has \(\chi(E_R) = 8, 0, \) or \(-8\). If \(b_0(E_R) = 1, 5.2.2\) applied to an empty quoter gives \(\chi(E_R) = -8\). Thus, it suffices to consider \((M - d)\)-surfaces with either \(\chi(E_R) = 8\) and \(d = 2, 4, \) or \(\chi(E_R) = 0\) and \(d = 2, 4, \) or \(\chi(E_R) = -8\) and \(d = 2\).

Case 1: \(\chi(E_R) = -8, d = 2\). The only topological type \(E_R = V_{10}\). There are two deformation families of real Enriques surfaces \(E\) with \(E_R = V_{10}\); they are both of type I and differ by whether \(w_2(E/\text{conj})\) is or is not 0 (see [DK3] and [DIK]). Since \(E_R\) has a single component, such a surface admits the Pontrjagin-Viro form if and only if \(w_2(E/\text{conj}) = 0\).

Case 2: \(\chi(E_R) = 0, d = 2\). All such surfaces are of type I (see [DK2]); hence,
they satisfy the hypotheses of 5.2.1(3) and the Pontrjagin-Viro form is well defined.

Case 3: \( \chi(E_R) = 0 \), \( d = 4 \). Among the five topological types, with \( E_R = 2S_1 \), \( S_1 \cup V_2, 2V_2, V_3 \cup V_1, \) and \( V_4 \cup S \) (see [DK1]), only the last one can satisfy 5.2.2. (Recall that an \( S_1 \) component must form a separate half.) Furthermore, the complex separation must be \( \{ (V_4 \cup S) \} \cup \{ \emptyset \} \); in particular, both the components of \( E_R \) are in one half. There are two deformation families of real Enriques surfaces \( E \) with \( E_R = \{ V_4 \cup S \} \cup \{ \emptyset \} \) (see [DIK]).\(^1\) They can be obtained by the construction of 6.1 from a triple \((Z; P, Q)\), where \( Z = \Sigma_4 \) is a rational ruled surface with a \((-4)\)-section, \( P \in [2e_\infty] \), and \( Q \in [e_0 + e_\infty] \). (Here \( e_0 \) is the exceptional \((-4)\)-section and \( e_\infty \) is the class of a generic section.) One type is obtained when \( Z_R = S_1 \) and \( P_R = \emptyset \); the other one, when \( Z_R = \emptyset \). In the former case, \( Z_R = S_1 \), one can apply Theorem 6.2.5: since \( P \) is of type II, the Pontrjagin-Viro form is not defined. Thus, it suffices to construct a surface with \( E_R = V_4 \cup S \) and well defined Pontrjagin-Viro form. This can be done as in 6.1 and 6.5, where \( Z' = \mathbb{R}P^1 \times \mathbb{R}P^1 \), \( P' \) is a pair of conjugate generatrices of bi-degree \((0, 1)\), and \( Q' \) is the union of a pair of generatrices of bi-degree \((1, 0)\) and a nonsingular curve of bi-degree \((2, 2)\).

Case 4: \( \chi(E_R) = 8 \), \( d = 2 \). There are three topological types, with \( E_R = 2V_1 \cup 3S, V_2 \cup 4S, \) and \( S_1 \cup 4S \) (see [DK1]), which we consider separately.

Each decomposition \( E_R = \{ E_R^{(1)} \} \cup \{ E_R^{(2)} \} \) of \( E_R = 2V_1 \cup 3S \) is realized by two deformation families of real Enriques surfaces, one of type I, and one of type II (see [DIK]). The surfaces of type I satisfy the hypotheses of 5.2.1(3) and, hence, have well defined Pontrjagin-Viro forms.

There is one deformation family of real Enriques surfaces \( E \) with \( E_R = \{ V_2 \} \cup \{ 4S \} \), one family of surfaces with \( E_R = \{ V_2 \cup 2S \} \cup \{ 2S \} \), and two families of surfaces with \( E_R = \{ V_2 \cup 4S \} \cup \{ \emptyset \} \) (see [DK3] and [DIK]).\(^2\) All these surfaces are of type I. In the first two cases the surfaces satisfy the hypotheses of 5.2.1(3) and, hence, have well defined Pontrjagin-Viro forms. In the last case the surfaces can be obtained by the construction of 6.1 and 6.5: one takes for \( Z' \) the projective

---

\(^1\)In [DK3] it is erroneously stated that there is one family.

\(^2\)In [DK3] it is erroneously stated that there is one family with \( E_R = \{ V_2 \cup 4S \} \cup \{ \emptyset \} \).
plane $\mathbb{R}p^2$, for $P'$, the union of two conics with two conjugate tangency points (so that $P_0 = \emptyset$), and for $Q'$, the union of a generic real line and the line through the singular points of $P'$. The conics of $Q'$ may be either both real or complex conjugate; in the former case $Q'$ is of of type II and the Pontrjagin-Viro form is not defined, in the latter case $Q'$ is of type I and the Pontrjagin-Viro form is defined due to Theorem 6.2.5.

There are two deformation families of real Enriques surfaces $E$ with $E_\mathbb{R} = \{S_1\} \cup \{4S\}$ (see [DK3] and [DIK]). They are obtained by the construction of 6.1 and 6.5 from a triple $(Z', P', Q')$, where $Z'$ is the plane $\mathbb{R}p^2$ (or hyperboloid $\mathbb{R}p^1 \times \mathbb{R}p^1$), $P'$ is a nonsingular $M$-curve of degree 4 (respectively, bi-degree $(4,2)$), and $Q'$ is a pair of conjugate lines (respectively, generatrices of bi-degree $(0,1)$). From Theorem 6.2.5 it follows that the Pontrjagin-Viro form is well defined in the latter case and is not defined in the former case (as $Z - Q_\mathbb{R}$ is nonorientable).

Case 5: $\chi(E_\mathbb{R}) = 8$, $d = 4$, i.e., $E_\mathbb{R} = 4S$. Only the decompositions $\{4S\} \cup \{\emptyset\}$ and $\{2S\} \cup \{2S\}$ can satisfy 5.2.2 (and, in fact, only these surfaces are of type I). Consider the two cases separately.

There are four deformation families of real Enriques surfaces $E$ with $E_\mathbb{R} = \{4S\} \cup \{\emptyset\}$ (see [DK]). They differ by the classes realized by the image of $X^{(1)}_\mathbb{R}$ in $X/\tau = E$ and $X/t^{(2)}$ (see 5.1); the four possibilities are $(w_2, w_2), (w_2, 0), (0, w_2), \text{ and } (0, 0)$. (Note that $X/t^{(2)}$ is diffeomorphic to an Enriques surface and $w_2(X/t^{(2)}) \neq 0$.) Since $E/\text{conj}$ can as well be represented as the quotient space of $X/t^{(2)}$ by an involution whose fixed point set is $X^{(1)}_\mathbb{R}/t^{(2)}$, only the first of the four families may possess Pontrjagin-Viro form. Such a surface can be obtained by the construction of 6.1 and 6.5. Take for $Z'$ the hyperboloid $\mathbb{R}p^1 \times \mathbb{R}p^1$. Let $(L_1, L_2)$ and $(M_1, M_2)$ be two pairs of conjugate generatrices of bi-degree $(1,0)$ and $(N_1, N_2)$ a pair of conjugate generatrices of bi-degree $(0,1)$. Pick a generic pair $(C_1, C_2)$ of conjugate members of the pencil generated by $L_1 + M_1 + N_1$ and $L_2 + M_2 + N_2$ and let $P' = C_1 + C_2$ and $Q' = N_1 + N_2$. ($P'$ is a real curve of type I with four nodes, which lie on $Q'$.) Existence of the Pontrjagin-Viro form follows from Theorem 6.2.5.

There is one deformation family of real Enriques surfaces $E$ with $E_\mathbb{R} = \{2S\} \cup \{2S\}$ (see [DIK]). A surface with Pontrjagin-Viro form is constructed similar to the previous case. One takes for $Z'$ the hyperboloid $\mathbb{R}p^1 \times \mathbb{R}p^1$, for $P'$, a real $M$-curve of bi-degree $(4,2)$ with two conjugate double points, and for $Q'$, the union of two conjugate generatrices through the singular points of $P'$.
