Supplementary Figure 1:
Evolution of highest infarct classes in postoperative (poMRI) vs. intraoperativeMRI (ioMRI) for matched cases with additional resection after ioMRI. (none = no infarct present)
Supplementary Figure 2: Illustrative case example:
33 y/o male with resection of a WHO grade III oligodendroglioma in F1. Intraoperative MRI (left) showed no signs of DWI restriction. However, after continued resection poMRI (right) showed a sector-shaped infarct at the posterior resection cavity. Postoperatively the patient showed no new neurological deficits.
Supplementary Figure 3:

(a, b) Comparison of relative changes in NIHSS (a) and mRS (b) at discharge compared to admission for cases with (red) and without (blue) additional resection after intraoperative MRI. Left plots facetted by major anatomical localization, right plots by anatomical localization and lateralization; only cases with a new infarction on postoperative MRI are shown.
