Abstract—The article considers free and forced oscillations of a system with six degrees of freedom with symmetrical and asymmetrical mass-inertial characteristics. The conditions of single-frequency oscillations are obtained. Initial deviations and initial velocities must be interconnected through one of the amplitude distribution coefficients. The differential equations of free vibrations of the system in principal coordinates are six independent linear differential equations of second order. Their common solution is obtained. We examine the possibility of reduction in the quantity of degrees of freedom of the considered system from six to two ones. Passing from six degrees of freedom to two was substantiated with the aid of the numerical experiments. According to calculations, linear and angular deflections of the transportation vehicle, which has six and two degrees of freedom, differ not more than by 10%. This fact indicates that it is possible to replace a study of a system with many degrees of freedom by a system with two degrees of freedom. An example of the transport system, which has six degrees of freedom with a system with two degrees of freedom, indicates that it is possible to replace a study of a system with many degrees of freedom by a system with two degrees of freedom. The transport system, which has six degrees of freedom with a system with two degrees of freedom, indicates that it is possible to replace a study of a system with many degrees of freedom by a system with two degrees of freedom. The transport system, which has six degrees of freedom with a system with two degrees of freedom, indicates that it is possible to replace a study of a system with many degrees of freedom by a system with two degrees of freedom. The transport system, which has six degrees of freedom with a system with two degrees of freedom, indicates that it is possible to replace a study of a system with many degrees of freedom by a system with two degrees of freedom.

Keywords—mechanical engineering; vibration effects; modeling; forced oscillations; mass-inertial characteristics

I. INTRODUCTION

Modeling machine engineering objects usually begins with the solution of the simplest tasks: modeling systems with one degree of freedom [1-3]; systems with unilateral constraints; controlled mechanical systems; systems with additional constraints. A further development of research is a system with many degrees of freedom. The systems under consideration have a complex structure; therefore, for an analytical solution, it is necessary to reduce systems to the simplest form and to the normal coordinates.

In practice [1, 4-10], the determination of the normal coordinates is a task of the same order of difficulty as a complete study of the free oscillations of this system in generalized coordinates. However, the normal coordinates are convenient for studying forced oscillations of the system [11-14], since the motion of the system in this case is differential equations that do not depend on each other.

It is advisable when considering a system with many degrees of freedom to consider a single-frequency mode, i.e. oscillations of the system, in which all points of the system under consideration oscillate with the same frequency.

The possibility of transition to a simplified system with two degrees of freedom makes it possible to obtain analytical calculations to estimate forced vibrations of a transportation vehicle. And reducing the system of differential equations, which describe the movement of engineering objects, to a
single higher order equation sometimes makes it easier to obtain analytical solutions [13-16].

II. SYSTEMS WITH SIX DEGREES OF FREEDOM

We consider free and forced oscillations of a system with six degrees of freedom with symmetrical and asymmetrical mass-inertial characteristics. When setting up a mathematical model of a mechanical system, standard assumptions for rolling stock dynamics were adopted. The model includes a transportation vehicle body having elastic and dissipative elements with intermediate load (Fig. 1).

With the help of the Lagrange equation of the second kind, a system of differential equations for the transportation vehicle model was set up:

\[
\begin{align*}
\sum \frac{k}{m} \ddot{x}_k + (\beta_1 + \beta_2) \dot{x}_k - \beta_1 \dot{x}_{11} - \beta_1 \dot{x}_{12} + \\
+ (\beta_1 \lambda_1 - \beta_2 \lambda_2) \phi_\alpha + (c_1 + c_2) \dot{x}_k - \\
- c_1 \dot{x}_{11} - c_2 \dot{x}_{12} + (c_1 \lambda_1 - c_2 \lambda_2) \phi_\alpha = 0; \\
m_{11} \ddot{x}_{11} - \beta_1 \dot{x}_k - (\beta_1 + \beta_2) \dot{x}_{12} + \\
+ (\beta_1 \lambda_1 - \beta_2 \lambda_2) \phi_\alpha + (c_1 + c_2) \dot{x}_{11} - \\
- c_1 \dot{x}_{11} - c_2 \dot{x}_{12} \phi_\alpha = 0; \\
m_{12} \ddot{x}_{12} - \beta_2 \dot{x}_k + (\beta_1 + \beta_2) \dot{x}_{11} + \\
+ (\beta_1 \lambda_1 - \beta_2 \lambda_2) \phi_\alpha + (c_1 + c_2) \dot{x}_{12} - \\
- c_1 \dot{x}_{11} - c_2 \dot{x}_{12} \phi_\alpha = 0; \\
I_1 \ddot{\phi}_\alpha + (\beta_1 \lambda_1 - \beta_2 \lambda_2) \phi_\alpha + (c_1 + c_2) \dot{\phi}_\alpha - \\
- c_1 \dot{\phi}_\alpha + c_2 \dot{x}_{12} \phi_\alpha = 0; \\
I_2 \ddot{\phi}_\alpha + (\beta_1 \lambda_1 - \beta_2 \lambda_2) \phi_\alpha + (c_1 + c_2) \dot{\phi}_\alpha - \\
- c_1 \dot{\phi}_\alpha + c_2 \dot{x}_{11} \phi_\alpha = 0,
\end{align*}
\]

where the following generalized coordinates are introduced: \(Z_k, Z_{11}, Z_{12}\) are current vertical displacements of the transportation vehicle's center of gravity, first and second intermediate loads, \(\phi_k, \phi_{11}, \phi_{12}\) are current angular displacements of the transportation vehicle's rotation and intermediate masses relative to their main inertia axes perpendicular to the longitudinal plane in which movement is examined.

It is quite difficult to obtain an analytical solution of equations (1). Therefore, we use the mathematical software package MathCAD to study them. On the resulting model in the MATHCAD package, the effect of the suspension parameters on the natural oscillations was studied. As a result of studying oscillations of a system with symmetrical and asymmetrical mass-inertial characteristics [1], it was concluded that the mass-inertial parameters of the system significantly influence the dynamic behavior of the transportation vehicle. The obtained vibration frequencies of the conservative system can be taken as the natural vibration frequencies of real transportation vehicles, including dampers. At the same time, even though resistances to oscillations are not very high, they strongly affect the amplitudes.

The differential equations of free vibrations of the system in normal coordinates are six independent linear differential equations of second order. Their common solution is obtained.

The conditions of single-frequency oscillations are obtained. Initial deviations and initial velocities must be interconnected through one of the amplitude distribution coefficients.

The method of obtaining the main coordinates is considered, which allows considering each of the obtained differential equations separately.

The general solution of the system of differential equations (2) is obtained.

\[
\begin{align*}
\sum (q_1 + q_2 + q_3 + q_4 + q_5 + q_6; \\
q_{11} = \mu_1 q_1 + \mu_2 q_2 + \mu_3 q_3 + \mu_4 q_4 + \mu_5 q_5 + \mu_6 q_6; \\
q_{12} = \mu_2 q_1 + \mu_1 q_2 + \mu_3 q_3 + \mu_4 q_4 + \mu_5 q_5 + \mu_6 q_6; \\
q_{11} = \mu_1 q_1 + \mu_2 q_2 + \mu_3 q_3 + \mu_4 q_4 + \mu_5 q_5 + \mu_6 q_6; \\
q_{12} = \mu_1 q_1 + \mu_2 q_2 + \mu_3 q_3 + \mu_4 q_4 + \mu_5 q_5 + \mu_6 q_6; \\
q_{12} = \mu_1 q_1 + \mu_2 q_2 + \mu_3 q_3 + \mu_4 q_4 + \mu_5 q_5 + \mu_6 q_6; \\
q_{12} = \mu_1 q_1 + \mu_2 q_2 + \mu_3 q_3 + \mu_4 q_4 + \mu_5 q_5 + \mu_6 q_6;
\end{align*}
\]

III. TRANSITION TO A SYSTEM WITH TWO DEGREES OF FREEDOM

The above is a system with six degrees of freedom. Let us examine the possibility of reduction in the quantity of degrees of freedom of the considered system from six to two ones [2].

Passing from six degrees of freedom to two was substantiated with the aid of the numerical experiments. Suppose that the transport system under investigation is asymmetric with respect to the main central axes of inertia. As a result of the calculations, we obtained that the period, amplitude and frequency of vertical oscillations of the object are \(T_1 \approx 0.458\) (sec), \(\lambda_1 \approx 1.47 \times 10^{-2}\) (m) and \(n_1 \approx 2.183\) (Hz), respectively. The characteristics of natural oscillations on the basis of the solution obtained are the following: \(T_2 \approx 0.4585\) (sec), \(\lambda_2 \approx 0.25\)°, \(n_2 \approx 2.181\) (Hz).

Since the intermediate masses \(m_{11}\) and \(m_{12}\) are small
compared to the mass of the transportation vehicle \( m_k \), we study a simplified model of the system.

We consider a transportation vehicle as a solid supported at two points on successively set springs with stiffnesses \( c_{11}, c_{12}, c_{21}, c_{22}, c_{31}, c_{32} \) (fig. 2).

The reduced stiffness of these springs is (3)

\[
\tilde{c}_{11} = \frac{c_{11} + c_{21}}{c_{11} + c_{21} + c_{22}}, \quad \tilde{c}_{12} = \frac{c_{12} (c_{11} + c_{22})}{c_{12} + c_{11} + c_{12}}
\]

Under the accepted assumptions, the system configuration can be determined using two independent variables: \( z_K \) is the vertical movement of the center of gravity and \( \phi_K \) is the angular movement of the transportation vehicle’s rotation.

\[
\begin{align*}
\left\{ m_k \ddot{z}_K + (\tilde{c}_{11} + \tilde{c}_{12}) z_K + (\tilde{c}_{11} L - \tilde{c}_{12} L_2) \phi_K = 0; \\
I_k \ddot{\phi}_K + (\tilde{c}_{11} L_1^2 + \tilde{c}_{12} L_2^2) \phi_K + (\tilde{c}_{11} L_1 - \tilde{c}_{12} L_2) z_K = 0.
\end{align*}
\]

As a result of the calculations, the following characteristics of the natural oscillations of the intermediate load were obtained: the period, amplitude and frequency of oscillations are \( T_1 \approx 0.459 \) (sec), \( \lambda_1 \approx 1.47 \times 10^{-2} \) (m) and \( n_1 \approx 2.179 \) (Hz), respectively; the period, amplitude and frequency of the vehicle are as follows: \( T_2 \approx 0.459 \) (sec), \( \lambda_2 \approx 0.25 \), \( n_2 \approx 2.179 \) (Hz) (fig. 3-4).

In fig. 3 and 4 the solid line indicates the movement of the transport system with six degrees of freedom, and the dotted line - with two ones.

The deviation of the linear and angular coordinates of a system with six degrees of freedom from a system with two degrees of freedom was estimated according to three norms [2]:

\[
\|x\|_1 = \max_i |x_i| \quad \text{is the first norm,} \\
\|x\|_2 = \sum_{i=1}^n |x_i| \quad \text{is the second norm,} \\
\|x\|_3 = \sqrt{\sum_{i=1}^n x_i^2} \quad \text{is the third norm.}
\]
In the second and third norms $n$ are equal to the number of points calculated on the period of the function.

Comparison of the results of calculations for a system with two and six degrees of freedom showed that the linear deviation calculated on the first norm is 4.6 %, and the angular one is 0.6 %. On the second norm, linear and angular deviations are, respectively, 1.4 % and 4.3 %. On the third norm they are 1.3 % and 3.8 %.

For a simplified system with two degrees of freedom, the differential equations describing the forced oscillations of the system (Fig. 5) take the form (5):

$$
\begin{align*}
    m_k \ddot{z}_K + (\bar{c}_{11} + \bar{c}_{12}) z_K + (\bar{c}_{11} L_1 - \bar{c}_{12} L_2) \phi_k &= F_1; \\
    I_k \ddot{\phi}_K + (\bar{c}_{11}^2 L_1^2 + \bar{c}_{12}^2 L_2^2) \phi_k + (\bar{c}_{11} L_1 - \bar{c}_{12} L_2) z_K &= F_2,
\end{align*}
$$

(5)
Here $F_1 = H_1 \sin pt$, $F_3 = H_2 \sin pt$, and, accordingly, the amplitude frequency characteristics response for the linear amplitude of the transportation vehicle oscillations $A_1$ will be determined by the expression:

$$H_1 (C_{22} - A_{22} p^2) - H_2 C_{12} \left[ C_{11} - A_{11} p^2 \right] \left[ (C_{23} - A_{22} p^2) - C_{12} \right] = 0,$$

for the angular amplitude of transportation vehicle vibrations $A_2$ is determined by the expression:

$$H_1 \left( C_{11} - A_{11} p^2 \right) - H_2 C_{21} \left( C_{11} - A_{11} p^2 \right) \left( C_{22} - A_{22} p^2 \right) - C_{12} = 0,$$

where

$$A_{11} = m_k, \; A_{11} = \bar{c}_{11} + \bar{c}_{12}, \; C_{12} = C_{21} = \bar{c}_{11} L_1 - \bar{c}_{12} L_2, \; A_{22} = I_k, \; C_{22} = \bar{c}_{11} L_1^2 + \bar{c}_{12} L_2^2.$$  

According to calculations linear and angular deflections of the transportation vehicle, which has six and two degrees of freedom, they differ not more than by 10%. This fact indicates that it is possible to replace a study of a system with six degrees of freedom with a system with two degrees of freedom.

In addition, a compelling force that influences the system and has a periodic (and not harmonic) nature is considered [1, 3].

The problem of finding the steady-state forced oscillations caused by a periodic piecewise constant driving force is considered.

$$Q(t+T) = Q(t)$$

where $T$ is the period of change of force (Fig. 6).

We obtain the system of differential equations:

$$\begin{bmatrix} A_{11} \ddot{z}_k + C_{11} \dot{z}_k + C_{12} \dot{\varphi}_k = Q(t); \\
A_{22} \ddot{\varphi}_k + C_{22} \dot{\varphi}_k + C_{21} \dot{z}_k = 0, 
\end{bmatrix}$$

where the coefficients are determined by the formula (8).

The normal coordinates of the system are obtained. As a result of the research, differential equations of motion of the system have been set up and an analytical solution has been obtained for the case of application of an external piecewise constant driving force.

IV. REDUCTION OF THE SYSTEM OF DIFFERENTIAL EQUATIONS OF A MECHANICAL ENGINEERING FACILITY TO THE SIMPLEST FORM

The above mechanical engineering facilities are described by a system of differential equations. We consider an example of a transport system that has three degrees of freedom (Fig. 7).

For the generalized coordinates we take vertical displacement $z$ and angular displacements $\varphi$ and $\psi$. We assume that the stiffnesses $\bar{c}_{11}$, $\bar{c}_{12}$, $\bar{c}_{21}$ and $\bar{c}_{22}$ are reduced and are calculated using $c_{11}$, $c_{12}$, $c_{21}$, $c_{22}$, $c_{31}$, $c_{32}$, $c_{33}$ and $c_{34}$, respectively.
The system of equations (11) describes the motion of the considered transport system.

\[
\begin{align*}
\ddot{z} + (\ddot{c}_{11} + \ddot{c}_{21} + \ddot{c}_{22} + \ddot{c}_{32})z + \\
+ (\ddot{c}_{12}L_1 + \ddot{c}_{22}L_2 - \ddot{c}_{22}L_2 - \ddot{c}_{32}L_2) \phi + \\
+ (\ddot{c}_{12}L_1 + \ddot{c}_{22}L_2 - \ddot{c}_{12}L_1 - \ddot{c}_{12}L_1) \psi = f_1; \\
I_z \dot{\phi} + (\ddot{c}_{12}L_1 + \ddot{c}_{22}L_2 - \ddot{c}_{12}L_1 - \ddot{c}_{12}L_1) z + \\
+ (\ddot{c}_{12}L_1 + \ddot{c}_{22}L_2 + \ddot{c}_{22}L_2 + \ddot{c}_{22}L_2) \phi + \\
+ (\ddot{c}_{12}L_1 + \ddot{c}_{22}L_2 - \ddot{c}_{12}L_1 - \ddot{c}_{12}L_1) z + \\
+ (\ddot{c}_{12}L_1 + \ddot{c}_{22}L_2 - \ddot{c}_{12}L_1 - \ddot{c}_{12}L_1) \phi + \\
+ (\ddot{c}_{12}L_1 + \ddot{c}_{22}L_2 + \ddot{c}_{22}L_2 + \ddot{c}_{22}L_2) \psi = f_2; \\
I_z \dot{\psi} + (\ddot{c}_{12}L_1 + \ddot{c}_{22}L_2 - \ddot{c}_{12}L_1 - \ddot{c}_{12}L_1) z + \\
+ (\ddot{c}_{12}L_1 + \ddot{c}_{22}L_2 - \ddot{c}_{12}L_1 - \ddot{c}_{12}L_1) \phi + \\
+ (\ddot{c}_{12}L_1 + \ddot{c}_{22}L_2 + \ddot{c}_{22}L_2 + \ddot{c}_{22}L_2) \psi = f_3.
\end{align*}
\]

After simplification, the system (11) takes the form:

\[
\begin{align*}
\ddot{z} + a_1 z + a_2 \phi + a_3 \psi = f_1; \\
\ddot{\phi} + s_1 z + s_2 \phi + s_3 \psi = f_2; \\
\ddot{\psi} + d_1 z + d_2 \phi + d_3 \psi = f_3.
\end{align*}
\]

Having done the obvious operations on the equations of system (12), we obtain:

\[
E_1 \psi^{VI} + E_2 \psi^{IV} + E_3 \psi + E_4 \psi = F_3
\]
The discrepancy between analytical calculations, mathematical modeling and experiments does not exceed 12%.

VI. CONCLUSION

Applying the concept of mathematical modeling to the transport system, we note that the model reflects the basic properties of the object under study to the extent necessary to assess its dynamic qualities. Free and forced oscillations of the system are considered for a given initial deviation from the equilibrium position. In practice, the problems like that are solved in the design of transportation vehicles. By changing the speed of the transport system, it is possible to determine the critical speeds and the corresponding maximum displacements in the suspension system. By changing the parameters of suspension, one can outline ways to reduce negative phenomena.

The obtained results of the dependence of the lateral displacement and the angle of the transportation vehicle, and of the first and second masses on the time indicate that the natural oscillations of the masses of transportation vehicle and the masses, which are the sum of two harmonic oscillations, are non-damping [15] since while solving the problem we disregarded the action of the inelastic resisting forces of the dampers. Since the periods of oscillations of the transport vary little in $T_1 \approx 0.7$ (sec), $T_2 \approx 0.66$ (sec), the oscillations $\zeta_1$ and $\zeta_2$ have the form of beatings. In case of symmetry breaking, the center of masses of the transportation vehicle has shifted by 7%, the movement has become a beating. As a result of studying oscillations of a system with symmetrical and asymmetrical mass-inertial characteristics [2], it was found that the amplitudes of oscillations with asymmetrical characteristics decreased. Thus, the mass-inertial parameters of the system significantly influence the dynamic behavior of the transport system.

Studies of systems with six degrees of freedom and systems with two degrees of freedom showed that they do not differ by more than 10%, which means that a system with two degrees of freedom describes the movement of a mechanical system with six degrees of freedom. A method is presented that allows one to obtain a closed solution for steady-state forced oscillations. The simplified model is further developed and supplemented, and the simulation results serve as the initial estimate for more complex models.

Processing and analysis of the obtained experimental results when compared with analytical calculations and modeling performed in MathCad confirmed the hypotheses that the parameters of oscillatory processes depend strongly on external perturbing influences and symmetry breaking. Antiresonance modes recommended by analytical studies were confirmed in experimental studies.
