TRACES ON OPERATOR IDEALS AND ARITHMETIC MEANS

VICTOR KAFTAL AND GARY WEISS*

Abstract. This article investigates the codimension of commutator spaces \([I, B(H)]\) of operator ideals on a separable Hilbert space, i.e., “How many traces can an ideal support?” We conjecture that the codimension can be only zero, one, or infinity. Using the arithmetic mean (am) operations on ideals introduced in [13] and the analogous arithmetic mean operations at infinity (am-∞) that we develop extensively in this article, the conjecture is proven for all ideals not contained in the largest am-∞ stable ideal and not containing the smallest am-stable ideal, for all soft-edged ideals (i.e., \(I = se(I) = IK(H)\)) and all soft-complemented ideals (i.e., \(I = scI = I/K(H)\)), which include all classical operator ideals we considered. The conjecture is proven also for ideals whose soft-interior, \(seI\), or soft-cover, \(scI\), are am-∞ stable or am-stable and for other classes of ideals. We show that an ideal of trace class operators supports a unique trace (up to scalar multiples) if and only if it is am-∞ stable. For a principal ideal, am-∞ stability is what we call regularity at infinity of the sequence of s-numbers of the generator. We prove for these sequences analogs of several of the characterizations of usual regularity. In the process we apply trace extension methods to two problems on elementary operators studied by V. Shulman. This article presents and extends several of the results announced in PNAS-US [19] and then expanded and developed in a series of papers [20]-[24].

1. Introduction

The study of operator ideals - two-sided ideals of the algebra \(B(H)\) of bounded linear operators on a complex separable infinite dimensional Hilbert space \(H\) - started with J. Calkin [7] in 1941. From early on (e.g., [17], [6], [28] and [3]), central in this area was the notion of commutator space and the related notion of trace. The commutator space (or commutator ideal) \([I, B(H)]\) of an ideal \(I\) is the linear span of the commutators of operators in \(I\) with operators in \(B(H)\). A trace on an operator ideal is a linear functional (not necessarily positive) that vanishes on its commutator space or, equivalently, that is unitarily invariant.

The introduction of cyclic cohomology in the early 1980’s by A. Connes and its linkage to algebraic K-theory by M. Wodzicki in the 1990’s provided additional motivation for the complete determination of the structure of commutator spaces. (Cf. [8], [9], [10] and [38].)

This was achieved by K. Dykema, T. Figiel, G. Weiss and M. Wodzicki [13] and [14] who fully characterized commutator spaces in terms of arithmetic (Cesaro) means of

monotone sequences [13, Theorem 5.6] thus concluding a line of research introduced in G. Weiss’ PhD thesis [34] (see also [36] and [37]) and developed significantly by N. Kalton in [26].

The introduction of arithmetic mean operations on ideals and the results in [13] in particular, opened up a new area of investigation in the study of operator ideals and have become an intrinsic part of the theory. To explore this area is the goal of our program outlined in [19], of which this paper and [20] are the beginning. In this paper we focus mainly on the question: “How many nonzero traces can an ideal support?” and on developing tools to investigate it.

From [13] we know that an ideal supports “no nonzero traces” precisely when the ideal is stable under the arithmetic mean (am-stable).

In Section 6 we prove that an ideal that does not contain the diagonal operator $\text{diag} < 1, \frac{1}{2}, \frac{1}{3}, \ldots >$ supports “one” nonzero trace precisely when the ideal is stable under the arithmetic mean at infinity (am-$\infty$ stable). Here, what is meant by “one” is that the ideal supports a trace that is unique up to scalar multiples.

In Section 7 we prove that “infinitely many” traces are supported by ideals whose soft-interior or soft-complement are not am-stable or not am-$\infty$ stable and by other classes of ideals as well. This motivates our conjecture that the number of traces that an ideal can support must always be either “none”, “one”, or “infinitely many”.

In the first part of this paper we develop the above mentioned notions of arithmetic mean, arithmetic mean at infinity, soft interior and soft complement of ideals as their interplay provides the tools for this study.

The arithmetic mean of operator ideals was introduced and played an important role in [13]; we review some of its properties in Section 2.

While the soft-interior and soft-complement of ideals have appeared implicitly in numerous situations in the literature, to the best of our knowledge they have never been formally studied before. We introduce them briefly in Section 3 and study their interplay with the am operations; we leave to [20] a more complete development of these notions and of the ensuing ideal classes.

The arithmetic mean at infinity was used among others in [1], [13], and [39] as an operation on sequences. In Section 4 we develop the properties of the am-$\infty$ operations on ideals which parallel only in part those of the am operations and we study their interplay with the soft-interior and soft-complement operations. The notion of regularity for sequences, which figured prominently in the study of principal ideals in [32], has a dual form for summable sequences that we call regularity at infinity (Definition 4.11). In Theorem 4.12 we link regularity at infinity to other sequence properties, including a Potter type inequality used by Kalton in [25] and Varga type properties (cf. [32]) and to the Matuszewska index introduced in this context in [13].

In Section 5, we study trace extensions from one ideal to another and in the process we obtain hereditariness (solidity) of the cone of positive operators $(\mathcal{L}_1 + [I, B(H)])^+$ where $\mathcal{L}_1$ is the trace class. (The analogous result for $(F + [I, B(H)])^+$, where $F$ is the finite rank ideal, is obtained in Corollary 6.2) These results are applied in Propositions 5.7 and 5.8 to two problems on elementary operators studied by V. Shulman (private communications related to [31]).
We do not know for which ideals, if not all, the cones \((J + [I, B(H)])^+\) are hereditary beyond the cases \(J = \{0\}, F, \mathcal{L}_1, I \subset J\) or \(J \subset [I, B(H)]\).

In Section 6 we characterize those ideals of trace class operators that support a unique trace (up to scalar multiples): they are precisely the \(am\)-\(\infty\) stable ideals (Theorem 6.6).

In Section 7 we bring the previously developed tools to bear on the question of how many traces an ideal can support.

Ideals divide naturally into three classes from the perspective developed here:

- the “small” ideals, i.e., the ideals contained in the largest \(am\)-\(\infty\) stable ideal \(st_{a\infty}(\mathcal{L}_1) \subset \mathcal{L}_1\), (see Definition 4.14)
- the “large” ideals, i.e., the ideals containing the smallest \(am\)-stable ideal \(st^a(\mathcal{L}_1)\), (see ibid)
- the “intermediate” ideals, i.e., all remaining ideals.

Intermediate ideals always support infinitely many traces, or more precisely, \([I, B(H)]\) has uncountable codimension in \(I\) (Theorem 7.2(iii)).

We conjecture that the codimension of \([I, B(H)]\) in \(I\) can be only one or infinity for small ideals and zero or infinity for large ideals.

The conjecture is proven for soft-edged ideals \((I = seI)\) and soft-complemented ideals \((I = scI)\) (Corollary 7.5). These include all the classical ideals we examined including all those investigated in [13].

A stronger result (Theorem 7.2) is that if \(seI\) (or, equivalently, \(scI\)) is not \(am\)-\(\infty\) stable (for small ideals) or \(am\)-stable (for large ideals), then \([I, B(H)]\) has uncountable codimension in \(I\).

This leaves the conjecture open for small ideals that are not \(am\)-\(\infty\) stable and for large ideals that are not \(am\)-stable but have \(am\)-stable soft interiors.

The key technical tool for these results is Theorem 7.1 which states that \([I, B(H)]\) has uncountable codimension in \(I\) whenever \(seI\) is not contained in \(F + [I, B(H)]\).

In Theorem 7.8 and Corollary 7.9 a different technique shows that \(I\) supports infinitely many traces for a class of ideals that include some cases where \(seI\) is \(am\)-stable.

Following this paper (the first of the program outlined in [19]) is [20] where we study the soft-interior and soft-complement operations on ideals and their interplay with the \(am\) and \(am\)-\(\infty\) operations. In forthcoming papers we will investigate:

1. Connections between (infinite) majorization theory, stochastic matrices, infinite convexity notions for ideals, diagonal invariance, and the \(am\) and \(am\)-\(\infty\) operations [24].

2. Lattice structure for \(B(H)\) and for some distinguished classes of ideals and their density properties. Example: between two distinct principal ideals, at least one of which is \(am\)-stable (resp., \(am\)-\(\infty\) stable), lies a third \(am\)-stable (resp., \(am\)-\(\infty\) stable) principal ideal [23].

3. First and second order arithmetic mean cancellation and inclusion properties [23]. Example: for which ideals \(I\) does \(I_a = J_a\) (resp., \(I_a \subset J_a\), \(I_a \supset J_a\)) imply \(I = J\) (resp., \(I \subset J\), \(I \supset J\))? Are there “optimal” ideals \(J\) for the inclusions \(I_a \subset J_a\) and \(I_a \supset J_a\)? In the principal ideal case concrete answers are obtained. For instance, \((\xi)_a = (\eta)_a\) implies \((\xi) = (\eta)\) for every \(\eta\) if and only if \(\xi\) is regular.
(4) In [21] conditions on $\xi$ are given which guarantee that $(\xi)_a^2 = (\eta)_a^2$ implies $(\xi)_a = (\eta)_a$ and a counterexample to this implication for the general case is provided, which settles a question of Wodzicki.

2. Preliminaries and the arithmetic mean

The natural domain of the usual trace $Tr$ on $B(H)$ (with $H$ a separable infinite-dimensional complex Hilbert space) is the trace class ideal $L_1$. However, ideals of $B(H)$ can support other traces.

**Definition 2.1.** A trace $\tau$ on an ideal $I$ is a unitarily invariant linear functional on $I$.

In this paper, traces are neither assumed to be positive nor faithful. All ideals are assumed to be proper.

Since $UXU^* \in [I, B(H)]$ for every $X \in I$ and every unitary operator $U$ and since unitary operators span $B(H)$, unitarily invariant linear functionals on an ideal $I$ are precisely the linear functionals on $I$ that vanish on the commutator space $[I, B(H)]$. Also known as the commutator ideal it is defined as the linear span of commutators of operators in $I$ with operators in $B(H)$. Thus traces can be identified with the elements of the linear dual of the quotient space $I/[I, B(H)]$ and hence to $I/[I, B(H)]$ itself.

A constant theme in the theory of operator ideals has been its connection to the theory of sequence spaces.

Calkin [7] established a correspondence between the two-sided ideals of $B(H)$ and the characteristic sets, i.e., the positive cones of $c_0^*$ (the collection of sequences decreasing to 0) that are hereditary and invariant under ampliations $c_0^* \ni \xi \to D_m\xi := <\xi_1, \ldots, \xi_1, \xi_2, \ldots, \xi_2, \xi_3, \ldots, \xi_3, \cdots>$ where each entry $\xi_i$ of $\xi$ is repeated $m$-times. The order-preserving lattice isomorphism $I \to \Sigma(I)$ maps each ideal to its characteristic set $\Sigma(I) := \{s(X) \mid X \in I\}$ where $s(X)$ denotes the sequence of $s$-numbers of $X$, i.e., all the eigenvalues of $|X| = (X^*X)^{1/2}$ repeated according to multiplicity, arranged in decreasing order, and completed by adding infinitely many zeroes if $X$ has finite rank. Conversely, for every characteristic set $\Sigma \subset c_0^*$, if $I$ is the ideal generated by $\{\text{diag } \xi \mid \xi \in \Sigma\}$ where $\text{diag } \xi$ is the diagonal matrix with entries $\xi_1, \xi_2, \ldots$, then we have $\Sigma = \Sigma(I)$. We shall also need the sequence space $S(I) := \{\xi \in c_0 \mid |\xi|^* \in \Sigma(I)\}$ where $|\xi|^*$ denotes the monotonization (in decreasing order) of $|\xi|$. Equivalently, $S(I) = \{\xi \in c_0 \mid \text{diag } \xi \in I\}$.

More recently Dykema, Figiel, Weiss, and Wodzicki [13] characterized the normal operators in the commutator spaces $[I, B(H)]$ in terms of spectral sequences. An important feature is that membership in commutator spaces (noncommutative objects) is reduced to certain conditions on associated sequences (commutative ones).

When $X \in K(H)$, the ideal of compact operators on $H$, denote an ordered spectral sequence for $X$ by $\lambda(X) := <\lambda(X)_1, \lambda(X)_2, \cdots>$, i.e., a sequence of all the eigenvalues of $X$ (if any), repeated according to algebraic multiplicity, completed by adding infinitely many zeroes when only finitely many eigenvalues are nonzero, and arranged
in any order so that \(|\lambda(X)|\) is nonincreasing. For any sequence \(\lambda = < \lambda_n >\), denote by \(\lambda_a\) the sequence of its arithmetic (Cesaro) mean, i.e.,

\[
\lambda_a := \frac{1}{n} \sum_{j=1}^{n} \lambda_j \geq_{n+1}.
\]

A special case of [13, Theorem 5.6] (see also [13, Introduction]) is:

**Theorem 2.2.** Let \(I\) be a proper ideal, let \(X \in I\) be a normal operator, and let \(\lambda(X)\) be any ordered spectral sequence for \(X\). Then \(X \in [I, B(H)]\) if and only if \(\lambda(X)_a \in S(I)\) if and only if \(|\lambda(X)_a| \leq \xi\) for some \(\xi \in \Sigma(I)\).

In fact, the conclusion holds under the less restrictive condition that \(\lambda(X)\) is ordered so that \(|\lambda(X)| \leq \eta\) for some \(\eta \in \Sigma(I)\) (see [13, Theorem 5.6]).

Arithmetic means first entered the analysis of \([L_1, B(H)]\) for a special case in [34] and [36] and for its full characterization in [26]. As the main result in [13] (Theorem 5.6) conclusively shows, arithmetic means are essential for the study of traces and commutator spaces in operator ideals. [13] also initiated a systematic study of ideals derived via arithmetic mean operations (am ideals for short). For the reader’s convenience we list the definitions and first properties from [13] Sections 2.8 and 4.3.

If \(I\) is an ideal, then the arithmetic mean ideals \(aI\) and \(I_a\), called respectively the pre-arithmetic mean and arithmetic mean of \(I\), are the ideals with characteristic sets

\[
\Sigma(aI) := \{\xi \in c_0^* | \xi_a \in \Sigma(I)\}
\]

\[
\Sigma(I_a) := \{\xi \in c_0^* | \xi = O(\eta_a) \text{ for some } \eta \in \Sigma(I)\}.
\]

The arithmetic mean-closure \(I^-\) and the arithmetic mean-interior \(I^o\) of an ideal (am-closure and am-interior for short) are defined as

\[
I^- := a(I_a) \quad \text{and} \quad I^o := (aI)_a
\]

and for any ideal \(I\), the following 5-chain of inclusions holds:

\[
aI \subset I^o \subset I \subset I^- \subset I_a.
\]

A restriction of Theorem 2.2 to positive operators can be reformulated in terms of pre-arithmetic means as:

\[
[I, B(H)]^+ = (aI)^+
\]

where \((aI)^+\) denotes the cone of positive operators in \(aI\). As a consequence, \([I, B(H)]^+\) is always hereditary, i.e., solid, \(aI \subset [I, B(H)] \subset I\), and \(aI\) and \(I\) are, respectively, the largest ideal contained in \([I, B(H)]\), and the smallest ideal containing \([I, B(H)]\) (for the latter see Remark 6.3(c)). Also, \(I = [I, B(H)]\) if and only if \(I = aI\). An ideal with the latter property is called arithmetically mean stable (am-stable for short) and it is easy to see, using the 5-chain mentioned above, that a necessary and sufficient condition for am-stability is that \(I = I_a\). Am-stability for many classical ideals and powers of ideals was studied extensively in [13, 5.13-5.27].

For \(\xi \in c_0^*\), denote by \((\xi)\) the principal ideal generated by \(\text{diag } \xi\). Notice that if \(\xi, \eta \in c_0^*\), then \((\xi) \subset (\eta)\) if and only if \(\xi = O(D_m \eta)\) for some \(m \in \mathbb{N}\); so \((\xi) = (\eta)\) if and only if both \(\xi = O(D_m \eta)\) and \(\eta = O(D_k \xi)\) hold for some \(m, k \in \mathbb{N}\). Thus \((\xi) = (\eta)\) implies \(\xi \sim \eta\) (i.e., \(\xi = O(\eta)\) and \(\eta = O(\xi)\)) if and only if \(\xi\) (and hence \(\eta\)) satisfies the
\[ \Delta_{1/2}\text{-condition}, \text{i.e., } \xi \prec D_2\xi \text{ (which is equivalent to } \xi \prec D_m\xi \text{ for all } m \in \mathbb{N}). \text{ In this context recall the well-known } \Delta_2\text{-condition for nondecreasing sequences } \sup_{n} \frac{a_n}{g_n} < \infty, \]
i.e., \( g \prec D_{1/2} g \) where \( (D_{1/m}g)_n := g_{mn} \).

The arithmetic mean \( \xi_a \) of a sequence \( \xi \in c^*_o \) always satisfies the elementary inequality \( D_2\xi_a \leq 2\xi_a \) and hence also the \( \Delta_{1/2}\)-condition. From this it follows easily that \( (\xi_a) = (\xi)_a \) and hence that the principal ideal \( (\xi) \) is am-stable if and only if \( \xi \succ \xi_a \), i.e., \( \xi \) is regular (cf. [16, p.143 (14.12)]). The notion of regularity plays a crucial role in Varga’s study of positive traces on principal ideals [32].

Of special importance in [13] and in this paper is the principal ideal \( (\omega) \), where \( \omega \) denotes the harmonic sequence \( < \frac{1}{n} > \). Elementary computations show that \( F_{a} = (\mathcal{L}_1)_a = (\omega) \) and that \( a(\omega) = \mathcal{L}_1 \). Hence \( aI \neq \{0\} \) if and only if \( \omega \in \Sigma(I) \).

An immediate but important consequence of Theorem 2.2 which will be used often throughout this paper is that \( \omega \in \Sigma(I) \) if and only if \( \mathcal{L}_1 \subset [I, B(H)] \) if and only if \( F \subset [I, B(H)] \).

3. **Soft interior and soft cover of ideals**

As mentioned in the Introduction, Theorem 7.1 which is one of our main results, is formulated in terms of the notion of the soft interior of an ideal.

**Definition 3.1.** Given an ideal \( I \), the **soft interior** of \( I \) is the ideal \( \text{si}I := IK(H) \) with characteristic set

\[
\Sigma(\text{si}I) := \{ \xi \in c^*_o \mid \xi \leq \alpha \eta \text{ for some } \alpha \in c^*_o, \eta \in \Sigma(I) \}.
\]

The **soft cover** of \( I \) is the ideal \( \text{sc}I \) with characteristic set

\[
\Sigma(\text{sc}I) := \{ \xi \in c^*_o \mid \alpha \xi \in \Sigma(I) \text{ for all } \alpha \in c^*_o \}.
\]

An ideal \( I \) is called **soft-edged** if \( \text{si}I = I \) and it is called **soft-complemented** if \( \text{sc}I = I \). A pair of ideals \( I \subset J \) is called a soft pair if \( I = \text{se}J \) and \( \text{sc}I = J \).

It is immediate to verify that the sets \( \Sigma(\text{se}I) \) and \( \Sigma(\text{sc}I) \) are indeed characteristic sets and that in the notations of [13, Section 2.8], \( \text{sc}I := I/K(H) \). Notice that \( \text{se}I \) is the largest soft-edged ideal contained in \( I \) and \( \text{sc}I \) is the smallest soft-complemented ideal containing \( I \). Also needed in this paper and easy to show is that, for every ideal \( I \), \( \text{se}I = \text{sc}I \), \( \text{se}I = \text{se}I \), \( \text{se}I \subset \text{sc}I \), and \( \text{se}I \subset \text{sc}I \) is a soft pair. (cf. [19, 20]).

**Remark 3.2.** This terminology is motivated by the fact that \( I \) is soft-edged if and only if for every \( \eta \in \Sigma(I) \) there is some \( \xi \in \Sigma(I) \) such that \( \eta = o(\xi) \). Similarly, \( I \) is soft-complemented if and only if, for every \( \xi \in c^*_o \setminus \Sigma(I) \), there is some \( \eta \in c^*_o \setminus \Sigma(I) \) such that \( \eta = o(\xi) \).

Soft-edged and soft-complemented ideals and soft pairs are common among the classical operator ideals, that is, ideals \( I \) whose \( S(I) \)-sequence spaces are classical sequence spaces. In [20] we show that the following are soft-complemented: countably generated ideals, the normed ideals \( \mathcal{G}_\phi \) induced by a symmetric norming function \( \phi \), Orlicz ideals \( \mathcal{L}_M \), Lorentz ideals generated by a nondecreasing \( \Delta_2 \)-function and, more generally, ideals whose characteristic set is a quotient of the characteristic set of a
soft-complemented ideal by an arbitrary set of sequences \( X \subset [0, \infty)^{\mathbb{Z}^+} \) and hence, in particular, Köthe duals \( \mathcal{L}_1/X \) and quotients \( I/J \) of a soft-complemented ideal by an arbitrary ideal (see [13] Section 2.8 for a discussion on quotients). Also the following are soft-edged: the ideals \( \mathfrak{G}_\phi^{(o)} \) (the closure of \( F \) under the norm of \( \mathfrak{S}_\phi \)), small Orlicz ideals \( \mathcal{L}_M^{(o)} \), and Lorentz ideals generated by a nondecreasing \( \Delta_2 \)-function. Moreover, \( \mathfrak{G}_\phi^{(o)} \subset \mathfrak{S}_\phi \) and \( \mathcal{L}_M^{(o)} \subset \mathcal{L}_M \) are natural examples of soft pairs. (See [13] for a convenient reference for these classical ideals.)

The condition \( seI \not\subset F + [I, B(H)] \) in Theorem 4.1 will need to be reformulated in terms of arithmetic means and arithmetic means at infinity. The first step is established by the following commutation relations between the arithmetic and pre-arithmetic mean ideal operations and the soft interior and soft complement operations.

**Lemma 3.3.** Let \( I \) be an ideal. Then

(i) \( sc(aI) \subset \ a(scI) \)

(ii) \( sc(aI) = \ a(scI) \) if and only if \( \omega \notin \Sigma(scI) \setminus \Sigma(I) \).

(iii) \( se(I_a) \subset \ a(scI) \)

(iv) \( a(scI) \) if and only if either \( I \not\subset \mathcal{L}_1 \) or \( I = \{0\} \).

**Proof.**

(i) For \( \xi \in \Sigma(sc(aI)) \) and all \( \alpha \in c_0^* \), by the definition of soft complement, \( \alpha\xi \in \Sigma(aI) \), that is, \( (\alpha\xi)_a \in \Sigma(I) \). But clearly \( \alpha\xi_a \leq (\alpha\xi)_a \) and hence \( \alpha\xi_a \in \Sigma(I) \). Thus \( \xi_a \in \Sigma(scI) \) and \( \xi \in \Sigma(a(scI)) \).

(ii) Recall from the end of Section 2 that for any ideal \( J \), \( aJ = \{0\} \) if and only if \( \omega \notin \Sigma(J) \). Consider separately the three cases: \( \omega \notin \Sigma(scI) \), \( \omega \in \Sigma(scI) \setminus \Sigma(I) \) and \( \omega \in \Sigma(I) \). If \( \omega \notin \Sigma(scI) \), then \( a(scI) = \{0\} \) and equality holds. If \( \omega \in \Sigma(scI) \setminus \Sigma(I) \), then \( a(scI) \neq \{0\} \) but \( aI = \{0\} \), so \( sc(aI) = \{0\} \) and equality fails. Finally assume that \( \omega \in \Sigma(I) \) and let \( \xi \in \Sigma(a(scI)) \) and \( \alpha \in c_0^* \). In case \( \xi \in l^1 \) then \( \alpha\xi_a = O(\omega) \), \( \alpha\xi \in \Sigma(aI) \) and thus \( \xi \in \Sigma(sc(aI)) \), so equality holds. In case \( \xi \notin l^1 \), it is easy to verify that \( \alpha\xi := (\alpha\xi)_a = \sum_j \frac{\alpha\xi_j}{\xi_j} \downarrow 0 \) and hence \( (\alpha\xi)_a = \alpha\xi_a \in \Sigma(I) \).

Thus \( \alpha\xi \in \Sigma(aI) \) and hence \( \xi \in \Sigma(sc(aI)) \) and equality holds.

(iii) If \( \xi \in \Sigma(sc(I_a)) \) then \( \xi \leq \alpha\eta_a \) for some \( \eta \in \Sigma(I) \) and \( \alpha \in c_0^* \). Then from the inequality in the proof of (i), \( \xi \leq (\alpha\eta)_a \in \Sigma((seI)_a) \).

(iv) Consider separately the three cases: \( I = \{0\} \), \( \{0\} \neq I \subset \mathcal{L}_1 \) and \( I \not\subset \mathcal{L}_1 \). In the case \( I = \{0\} \) the equality is trivial, and if \( \{0\} \neq I \subset \mathcal{L}_1 \), it fails trivially since \( (seI)_a = I_a = (\omega) \) (recalling that \( F_0 = (\mathcal{L}_1)_a = (\omega) \) and since \( \omega \) is not soft-edged. In the case that \( I \not\subset \mathcal{L}_1 \), for each \( \xi \in \Sigma((seI)_a) \), \( \xi \leq \rho_a \) for some \( \rho \in \Sigma(seI) \), i.e., \( \rho \leq \alpha\eta \) for some \( \eta \in \Sigma(I) \) and \( \alpha \in c_0^* \). By adding to \( \eta \) if necessary an element of \( \Sigma(I) \setminus l^1 \), one can insure that \( \eta \notin l^1 \), in which case, from the proof of (i'), again there is an \( \tilde{\alpha} \in c_0^* \) for which \( (\alpha\eta)_a = \tilde{\alpha}\eta_a \). But then \( \xi \leq \tilde{\alpha}\eta_a \in \Sigma((se(I_a)) \). By (ii) equality holds. \( \square \)
Proposition 3.4. Let $I$ be an ideal. Then the following are equivalent.

(i) $seI$ is am-stable
(ii) $scI$ is am-stable
(iii) $seI \subseteq aI$
(iii') $seI \subseteq [I, B(H)]$
(iv) $scI \supseteq I_a$

Proof. Assume first that $I \not\subset L_1$.

(i) $\Rightarrow$ (iii) Since $seI \subset I$ and the pre-arithmetic mean is inclusion preserving, $seI = a(seI) \subset aI$.

(iii) $\iff$ (iii') Obvious since $[I, B(H)]^+ = aI^+$ by Theorem 2.2.

(iii) $\Rightarrow$ (ii) Condition (ii) is immediate from the chain of relations $\ldots \subseteq scI \subseteq scI \subset scI \supseteq I_a$. For the first equality, recall the paragraph following Definition 3.1; $sc$ being inclusion preserving implies the first inclusion; Lemma 3.3(i) implies the second inclusion; and the 5-chain of inclusions implies the last inclusion.

(ii) $\Rightarrow$ (iv) From $I \subset scI$ it follows that $I_a \subset (scI)_a = scI$.

(iv) $\Rightarrow$ (i) In case $I \not\subset L_1$, $(scI)_a = sc(I_a) \subset scI = seI \subset (seI)_a$, where the first equality follows from Lemma 3.3(ii'), the first inclusion holds since $se$ is inclusion preserving, the second equality holds for all ideals (recall again the paragraph following Definition 3.1) and the last inclusion follows from the 5-chain.

In case $I \subset L_1$, if $I = \{0\}$ then all four conditions are trivially true and if $I \not\subset \{0\}$ then all four are false. Indeed the arithmetic mean of any nonzero ideal, and hence every nonzero am-stable ideal, must contain $(\omega)$ while $I \subset L_1$ implies that $seI \subset scI \subset L_1 \not\subset (\omega)$, which shows that (i), (ii), and (iv) are false. And since $aI \subset a(L_1) = \{0\}$ (recall the last paragraph of Section 2) but $seI \neq \{0\}$, (iii) too is false.

Remark 3.5. The $se$ and $sc$ operations preserve am-stability by Lemma 3.3(i) and Proposition 3.4. But am-stability of $seI$ (or $scI$) does not imply am-stability of $I$ as shown by the construction in Theorem 7.8.

4. Arithmetic mean at infinity

Since $\xi_\infty \asymp \omega$ for every $0 \neq \xi \in (\ell^1)^* := \ell^1 \cap c_0^*$, nonzero ideals $I \subset L_1$ all have arithmetic mean $I_a = (\omega)$. Thus the (Cesaro) arithmetic mean is not adequate for distinguishing between ideals contained in $L_1$. For such ideals, one needs to employ instead the arithmetic mean at infinity

$$\xi_\infty := < \frac{1}{n} \sum_{n+1}^{\infty} \xi_j >$$

(see [13] Section 2.1 (16), [25], [39]).

In this section we develop properties of the am-$\infty$ operation on sequences including a characterization of $\infty$-regular sequences which is dual to the known characterization of regular sequences and we introduce and investigate the am-$\infty$ operations on ideals. This will lead us to Proposition 4.20 which we find essential for Section 7.
The following lemma analyzes the relations between the am-∞ operation and the $D_m$ operations on sequences. Recall that if $j = mn - p$ with $n, p$ integers, $n \geq 1$, and $0 \leq p \leq m - 1$, then $(D_m \xi)_j = \xi_n$.

**Lemma 4.1.** Let $\xi \in (\ell^1)^*$. Then for $m = 2, 3, \ldots$ one has

(i) $D_m \xi_{a_\infty} \leq (D_m \xi)_{a_\infty}$

(ii) $(D_m \xi_{a_\infty})_j \geq ((D_{m-1} \xi)_{a_\infty})_j$ when $j \geq (m-1)(m-2)$

(iii) $(D_m \xi_{a_\infty})_j \geq \frac{1}{2(m-1)}(D_{m-1} \xi)_j$ when $j \geq 2m(m-1)$

(iv) $(D_{1/m} \xi)_{j} := \xi_{m_j} \leq \frac{1}{m-1}(\xi_{a_\infty})_j$ for all $j$.

**Proof.**

(i) Let $j = mn - p$ with $n, p$ integers, $n \geq 1$, and $0 \leq p \leq m - 1$. Then

\[
(D_m \xi_{a_\infty})_j = \frac{1}{mn-p} \sum_{n+1}^{\infty} (D_m \xi)_i = \frac{1}{mn-p} (p \xi_n + m \sum_{n+1}^{\infty} \xi_i)
\]

\[
= \frac{p}{mn-p} \xi_n + \frac{mn}{mn-p} (\xi_{a_\infty})_n
\]

\[
= \frac{p}{mn-p} \xi_n + \frac{mn}{mn-p} (D_m \xi_{a_\infty})_j \geq (D_m \xi_{a_\infty})_j.
\]

(ii) Let $j = mn - p$ as above. Then

\[
(D_m \xi_{a_\infty})_j = (\xi_{a_\infty})_n = (D_{m-1} \xi_{a_\infty})_{(m-1)n} = ((D_{m-1} \xi)_{a_\infty})_{(m-1)n}
\]

\[
\geq ((D_{m-1} \xi)_{a_\infty})_{j}.
\]

The third equality follows from the proof of (i) for the case $p = 0$, and the inequality holds since $(D_{m-1} \xi)_{a_\infty}$ is nonincreasing and $j \geq (m-1)(m-2)$ implies $j \geq (m-1)n$ by elementary calculation.

(iii) Let $2m(m-1) \leq j = mn - p = (m-1)(n+k) - p'$ where $0 \leq p \leq m - 1$ and $0 \leq p' \leq m - 2$, and hence $k \geq 1$. Then

\[
(D_m \xi_{a_\infty})_j = (\xi_{a_\infty})_n = \frac{1}{n} \sum_{n+1}^{\infty} \xi_j \geq \frac{1}{n} \sum_{n+1}^{n+k} \xi_j
\]

\[
\geq \frac{k}{n} \xi_{n+k} = \frac{k}{n} (D_{m-1} \xi)_j \geq \frac{1}{2(m-1)}(D_{m-1} \xi)_j
\]

where the latter inequality holds since $mn \geq j \geq 2m(m-1)$ and hence

\[
\frac{k}{n} = \frac{1}{m-1} (1 + \frac{p'}{n}) \geq \frac{1}{m-1} (1 - \frac{m-1}{n}) \geq \frac{1}{2(m-1)}.
\]

(iv) Immediate by the monotonicity of $\xi$ since then

\[
(m-1)j \xi_{mj} \leq \sum_{i=j+1}^{mj} \xi_i \leq j(\xi_{a_\infty})_j.
\]

\[\square\]
Remark 4.2. It is easy to see that the bounds in (i), (ii), and (iv) are sharp. In lieu of the bound \( \frac{1}{2(m-1)} \) in (iii) we can obtain \( \frac{1}{m-1} \) for any \( \epsilon > 0 \), but not for \( \epsilon = 0 \), i.e., \( D_m \xi_{a,\infty} \) does not majorize \( \frac{1}{m-1} D_m \xi \), even for \( j \) large enough. Indeed, for any \( j \), set \( \xi_i = 1 \) for \( 1 \leq i \leq 2j - 1 \) and 0 elsewhere. Then 
\[
(D_j \xi_{a,\infty})_{2j-1} = (\xi_{a,\infty})_j = \frac{1}{2j} < 1 = \xi_{2j-1}.
\]

Corollary 4.3. If \( \xi \in (\ell^1)^* \) then \( (\xi) \subset (\xi_{a,\infty}) \).

Proof. By Lemma 4.1 (iii) for \( m = 2 \) we have \( \xi_j \leq 2(D_2 \xi_{a,\infty})_j \) for \( j \geq 4 \), and thus \( \xi \in \Sigma((\xi_{a,\infty})) \).

In contrast to the arithmetic mean case where the sequence \( \xi_a \) always satisfies the \( \Delta_{1/2} \)-condition, Example 4.3 (ii) below shows that this is not always true for \( \xi_{a,\infty} \). Moreover, Example 4.3 (iii) shows that \( \xi_{\infty} \) may satisfy the \( \Delta_{1/2} \)-condition while \( \xi \) does not. Corollary 4.3 (iii) provides a necessary and sufficient condition for \( \xi_{a,\infty} \) to satisfy the \( \Delta_{1/2} \)-condition.

Corollary 4.4. Let \( \xi \in (\ell^1)^* \).

(i) If \( \xi \) satisfies the \( \Delta_{1/2} \)-condition, so does \( \xi_{a,\infty} \).
(ii) \( \xi_{a,\infty} \) satisfies the \( \Delta_{1/2} \)-condition if and only if \( \xi = O(\xi_{a,\infty}) \).

Proof.

(i) If \( D_2 \xi \leq M \xi \) for some \( M > 0 \), then by Lemma 4.1 (i), \( D_2 \xi_{a,\infty} \leq (D_2 \xi)_{a,\infty} \leq M \xi_{a,\infty} \).

(ii) If \( \xi_{a,\infty} \) satisfies the \( \Delta_{1/2} \)-condition then \( \xi = O(D_2 \xi_{a,\infty}) = O(\xi_{a,\infty}) \) by Lemma 4.1 (iii).

Conversely, assume that \( 0 \neq \xi = O(\xi_{a,\infty}) \), i.e., \( \xi_k \leq \frac{M}{k} \sum_{j=k+1}^{\infty} \xi_j \) for some \( M > 0 \) and all \( k \). Then \( \xi_k > 0 \) for all \( k \) and

\[
\frac{\sum_{j=n+1}^{\infty} \xi_j}{\sum_{j=2n+1}^{\infty} \xi_j} = \prod_{k=n+1}^{2n} \left( 1 + \frac{\xi_k}{\sum_{j=k+1}^{\infty} \xi_j} \right) \leq \prod_{k=n+1}^{2n} \left( 1 + \frac{M}{k} \right) = e^{\sum_{k=n+1}^{2n} \log(1 + \frac{M}{k})} \leq e^{M \sum_{k=n+1}^{2n} \frac{1}{k}} \leq 2^M.
\]

Hence \( \frac{(\xi_{a,\infty})_n}{(\xi_{a,\infty})_{2n}} \leq 2^{M+1} \) for all \( n \), i.e., \( \xi_{a,\infty} \) satisfies the \( \Delta_{1/2} \)-condition.

Example 4.5.

(i) Let \( \xi = \omega^p \) where \( p > 1 \). Then \( \xi_{a,\infty} \preceq \xi \) satisfies the \( \Delta_{1/2} \)-condition.

(ii) Let \( \xi = < q^n > \) where \( 0 < q < 1 \). Then \( \xi_{a,\infty} = o(\xi) \) and neither sequence satisfies the \( \Delta_{1/2} \)-condition.

(iii) Let \( n_k \) be an increasing sequence of integers for which \( n_k \geq kn_{k-1} \) (with \( n_1 = 1 \) and \( k \geq 2 \)), let \( \epsilon < \epsilon_k > \in \ell^p \) where \( \sum_{k=1}^{\infty} \epsilon_k n_k < \infty \), and let \( \xi_n := \epsilon_n \) for \( n_{k-1} < n \leq n_k \). Then \( \xi := < \xi_n > \in (\ell^1)^* \), \( \xi \) does not satisfy the \( \Delta_{1/2} \)-condition and \( (\xi) \neq (\xi_{a,\infty}) \), but \( \xi_{a,\infty} \) satisfies the \( \Delta_{1/2} \)-condition if and only if \( \epsilon_k n_k = O(\sum_{j=k+1}^{\infty} \epsilon_j n_j) \).

(iv) \( \xi = O(\xi_{a,\infty}) \) and \( \xi \) satisfies the \( \Delta_{1/2} \)-condition for \( \xi \) any of the sequences \( \omega/\log^p \), \( \omega/\log(\log \log)^p \), \( \omega/\log(\log \log(\log \log \log))^p \), . . . \( (p > 1) \).

Proof. The verification of (i), (ii) and (iv) is left to the reader. For (iii) let us note that if \( \frac{\epsilon_k n_k}{\epsilon_k} \leq M \) for some constant \( M \) and all \( k > 1 \), then \( \epsilon_k n_k > \frac{\epsilon_k}{M \epsilon_k} \epsilon_1 n_1 \) which is impossible because \( \epsilon_k n_k \) is summable. Thus the ratios \( \frac{\epsilon_k}{\epsilon_k} \) are unbounded and hence \( \xi \) does not satisfy the \( \Delta_{1/2} \)-condition. Moreover, \( \xi_{a,\infty} \neq O(D_m \xi) \) for every \( m \). Indeed for
every pair of integers $m, p > 1$, choose $k = m^2p^2$. Since $n_k > kn_{k-1} > pn_{k-1} > n_{k-1}$, then
\[
\left(\frac{\xi_{a_{\infty}}}{D_m\xi}\right)_{mpn_{k-1}} = \left(\frac{\xi_{a_{\infty}}}{\xi_{mpn_{k-1}}}\right) = \frac{1}{\epsilon_kmpn_{k-1}} \sum_{j=mpn_{k-1}}^{\infty} \xi_j \\
\geq \frac{1}{\epsilon_kmpn_{k-1}} \sum_{j=mpn_{k-1}}^{kn_{k-1}} \xi_j = \frac{m^2p^2n_{k-1} - mpn_{k-1}}{mpn_{k-1}} = mp - 1.
\]

Thus $\xi_{a_{\infty}} \neq O(D_m\xi)$ and hence $\xi_{a_{\infty}} \notin \Sigma((\xi))$. Finally, it is straightforward to verify that the given condition, $\epsilon_k = O\left(\frac{1}{n_k} \sum_{j=k+1}^{\infty} \epsilon_jn_j\right)$, is equivalent to the condition $\xi = O(\xi_{a_{\infty}})$, and hence by Corollary 4.12, is equivalent to $\xi_{a_{\infty}}$ satisfying the $\Delta_{1/2}$-condition.

Examples (i) and (ii) are sequences regular at infinity while (iii) and (iv) are not (see Definition 4.11 and Theorem 4.12).

An immediate consequence of Lemma 4.6(i) and (ii) is that the following definition yields characteristic sets.

**Definition 4.6.** Let $I$ be an ideal. Then $a_{\infty}I$ when $I \neq \{0\}$ and $I_{a_{\infty}}$ when $I$ is arbitrary are the ideals with characteristic sets
\[
\Sigma(a_{\infty}I) := \{\xi \in (\ell^1)^* \mid \xi_{a_{\infty}} \in \Sigma(I)\}
\]
\[
\Sigma(I_{a_{\infty}}) := \{\xi \in c_o^* \mid \xi = O(\eta_{a_{\infty}}) \text{ for some } \eta \in \Sigma(I \cap L_1)\}.
\]

Notice that $a_{\infty}I \subset L_1$ and $I_{a_{\infty}} = (I \cap L_1)_{a_{\infty}}$ by definition and that for all $\xi \in (\ell^1)^*$ one has $\xi_{a_{\infty}} = o(\omega)$, i.e., $I_{a_{\infty}} \subset se(\omega)$ for every ideal $I$ and therefore $a_{\infty}I = a_{\infty}(I \cap se(\omega))$. In particular, $L_1 \subset a_{\infty}(se(\omega))$ and hence $L_1 = a_{\infty}(se(\omega))$. And like the arithmetic and pre-arithmetic mean, the arithmetic mean and pre-arithmetic mean at $\infty$ are inclusion preserving.

**Lemma 4.7.** For $\xi \in c_o^*$,
\[
(\xi)_{a_{\infty}} = \begin{cases} 
(\xi_{a_{\infty}}) & \text{if } \xi \in \ell^1 \\
se(\omega) & \text{if } \xi \notin \ell^1.
\end{cases}
\]

In particular, if an ideal $I \not\subset L_1$ then $I_{a_{\infty}} = se(\omega)$, and moreover $(L_1)_{a_{\infty}} = se(\omega)$.

**Proof.** Assume first that $\xi \in \ell^1$. By definition $\xi_{a_{\infty}} \in \Sigma((\xi)_{a_{\infty}})$ so $(\xi_{a_{\infty}}) \subset (\xi)_{a_{\infty}}$. For the reverse inclusion, if $\eta \in \Sigma((\xi)_{a_{\infty}})$ then $\eta \leq \xi_{a_{\infty}}$ for a summable $\xi \in \Sigma((\xi))$. Since $\zeta \leq MD_m\xi$ for some $M > 0$ and $m \in \mathbb{N}$, by Lemma 4.1 (ii),
\[
(\xi_{a_{\infty}}) j \leq M((D_m\xi)_{a_{\infty}}) j \leq M(D_{m+1}\xi_{a_{\infty}}) j
\]
for $j \geq m(m - 1)$. Since $D_{m+1}\xi_{a_{\infty}} \in \Sigma((\xi_{a_{\infty}})), \eta \in \Sigma((\xi_{a_{\infty}}))$ and so $(\xi)_{a_{\infty}} \subset (\xi)_{a_{\infty}}$.

Assume now that $\xi \notin \ell^1$. It is not hard to show that $\min(\xi, \omega) \notin \ell^1$, so by passing if necessary to a sequence $(\ell^1)^* \not\subset \ell^1 = o(\min(\xi, \omega))$, one can assume without loss of generality that $\xi = o(\omega)$. For each $\zeta \in \Sigma(se(\omega))$, by passing if necessary to $\zeta' := \omega \uni(\frac{\xi}{\zeta}) \geq \zeta$ where $\uni \gamma$ is the smallest monotone nonincreasing sequence majorizing $\gamma$ and is given by $(\uni \gamma)_n := \sup_{j \geq n} \gamma_j$, one can assume without loss of
generality that \( \zeta = \alpha \omega \) for some \( \alpha \in c^*_o \) and that \( \alpha_1 \geq 1 \). To prove that \( \zeta \in \Sigma((\xi)_{a_\infty}) \), set \( m_\alpha = 0 \) and choose \( n_1 \geq 1 \) so that \( n_1 \xi_{n_1} \leq \frac{1}{2} \) and \( \alpha_{n_1} \leq \frac{1}{2} \). Since \( \xi \) is not summable, choose the first integer \( m_1 \geq n_1 \) for which \( \sum_{j=m_1}^{m_1} \xi_j \geq \alpha_1 \), and since \( \xi_{n_1} \leq \frac{1}{2} \) one also has \( \sum_{j=n_1}^{m_1} \xi_j \leq \alpha_1 + \frac{1}{2} \). Now choose \( n_2 > m_1 \) and \( m_2 \geq n_2 \) so that \( n_2 \xi_{n_2} \leq \frac{1}{2^2} \), \( \alpha_{n_2} \leq \frac{1}{2^2} \) and \( \frac{1}{2} \leq \sum_{j=n_2}^{m_2} \xi_j \leq 1 \). Iterating obtains the sequences, \( m_k \geq n_k > m_{k-1} \) so that, for \( k \geq 2 \), \( n_k \xi_{n_k} \leq \frac{1}{2^k} \), \( \alpha_{n_k} \leq \frac{1}{2^k} \) and \( \frac{1}{2^{k-1}} \leq \sum_{j=n_k}^{m_k} \xi_j \leq \frac{1}{2^{k-2}} \).

Define \( \eta_n = \begin{cases} \xi_{n_k} & \text{for } m_{k-1} < n \leq n_k \\ \xi_n & \text{for } n_k \leq n \leq m_k \end{cases} \). Then \( \eta = < \eta_n > \in c^*_o \) and \( \eta \leq \xi \). Since

\[
\sum_{j=m_k-1}^{n_k-1} \eta_j = (n_k - m_{k-1} - 1)\xi_{n_k} < n_k \xi_{n_k} \leq \frac{1}{2^k} \quad \text{and} \quad \sum_{j=n_k}^{m_k} \eta_j = \sum_{j=n_k}^{m_k} \xi_j \leq \frac{1}{2^{k-2}},
\]

one has \( \eta \in \ell^1 \). Moreover, for \( k \geq 2 \) and \( n_k-1 \leq n \leq n_k \) one has

\[
\sum_{n+1}^{n_k} \eta_j \geq \sum_{n_k}^{m_k} \xi_j \geq \frac{1}{2^{k-1}} \geq \alpha_{n_k-1} \geq \alpha_n;
\]

for \( 1 \leq n < n_1 \) one has \( \sum_{n+1}^{n_1} \eta_j \geq \sum_{n_1}^{m_1} \xi_j \geq \alpha_1 \geq \alpha_n \). Thus \( \eta \in (\ell^1)^* \), \( \eta \leq \xi \) and \( \alpha \leq < \sum_{n+1}^{n_1} \eta_j > \). Therefore \( \zeta = \alpha \omega \leq \eta_{a_\infty} \) and hence \( \zeta \in \Sigma((\xi)_{a_\infty}) \). Since \( \zeta \in \Sigma(se(\omega)) \) was arbitrary, \((\xi)_{a_\infty} \supseteq se(\omega)\). But \( I_{a_\infty} \subset se(\omega) \) for every ideal \( I \), so one has equality. Thus \( I_{a_\infty} = se(\omega) \) when \( I \not\subset \mathcal{L}_1 \). Moreover,

\[
(\mathcal{L}_1)_{a_\infty} = (\mathcal{L}_1 \cap (\omega))_{a_\infty} = (\omega)_{a_\infty} = se(\omega).
\]

Notice that to prove directly that \( se(\omega) \subset (\mathcal{L}_1)_{a_\infty} \), it would only be necessary to show that for all \( \alpha \in c^*_o \), \( \alpha \leq < \sum_{n+1}^{n_1} \eta_j > \) for some \( \eta \in (\ell^1)^* \). This is equivalent to the well-known fact that \( \alpha \) has a convex majorant in \( c^*_o \) (see [4, p. 203]). But for the proof that \( se(\omega) \subset (\xi)_{a_\infty} \) we needed to prove that the convex majorant, \( < \sum_{n+1}^{n_1} \eta_j > \), of \( \alpha \) can be chosen so that additionally \( \eta \leq \xi \).

Recall from Section 2 (see the paragraph following Theorem 2.22) that the am-ideals satisfy the 5-chain of inclusions. The situation is slightly more complicated for the am-\( \infty \) case since the inclusion \( I \subset I_{a_\infty} \) holds if and only if \( I \subset se(\omega) \), as we shall see in the next proposition. We shall also see there that the 5-chain of inclusions remains valid for all ideals \( I \) contained in \( \mathcal{L}_1 \):

\[
a_\infty I \subset (a_\infty I)_{a_\infty} \subset I \subset a_\infty (I_{a_\infty}) \subset I_{a_\infty}.
\]

More generally,

**Proposition 4.8.** Let \( I \neq \{0\} \) be an ideal.

(i) \( \{0\} \neq a_\infty I \subset (a_\infty I)_{a_\infty} \subset I \)

(ii) \( I \cap \mathcal{L}_1 \subset a_\infty (I_{a_\infty}) \subset I_{a_\infty} \)

(iii) \( a_\infty I = (a_\infty (I_{a_\infty}))_{a_\infty} \) and the map \( I \to (a_\infty I)_{a_\infty} \) is idempotent.

(iv) \( I \subset I_{a_\infty} \) if and only if \( I \subset se(\omega) \).

**Proof.**

(i) and (ii) The inclusions \( a_\infty I \subset I \) and \( I \cap \mathcal{L}_1 \subset I_{a_\infty} \) follow from Definition 4.16 and Corollary 4.3. Applying the first inclusion to \( I_{a_\infty} \) and the second to \( a_\infty I \) obtains
\[ a_\omega(I_{a_\omega}) \subset I_{a_\infty} \text{ and } a_\omega I = a_\infty I \cap L_1 \subset (a_\infty I)_{a_\omega}. \] The remaining two inclusions follow directly from Definition 4.6. And since \( <1,0,\ldots>_a=0, a_\infty I \neq \{0\} \) for all \( I \neq \{0\} \).

(ii) By (i) and (i'), \( a_\omega((a_\infty I)_{a_\omega}) \subset a_\infty I = a_\infty I \cap L_1 \subset a_\infty((a_\infty I)_{a_\omega}) \).

(iii) If \( J_{a_\infty} \subset I \) then, by (i'), one has \( J \cap L_1 \subset a_\infty(J_{a_\infty}) \subset a_\infty I \). Conversely, if \( J \cap L_1 \subset a_\infty I \) then, by (i) and the paragraph preceding Lemma 4.7, one has \( J_{a_\infty} = (J \cap L_1)_{a_\infty} \subset (a_\infty(I_{a_\infty}))_{a_\omega} \subset I \).

(iv) That \( I \cap se(\omega) \subset I_{a_\infty} \) is a simple consequence of Corollary 4.9 and Lemma 4.7. In particular, \( I \subset se(\omega) \) implies \( I \subset I_{a_\infty} \). The converse implication is automatic since, by definition, \( I_{a_\infty} \subset se(\omega) \). \hfill \( \square \)

Immediate consequences of Proposition 4.8(iii), Lemma 4.7, and the identities \( sc se(\omega) = sc(\omega) = (\omega) \) and \( se sc I = se I \subset I \) are:

**Corollary 4.9.** Let \( I \neq \{0\} \) be an ideal.

(i) \( a_\omega I = L_1 \) if and only if \( se(\omega) \subset I \) if and only if \( \omega \in \Sigma(se I) \).

(ii) \( I_{a_\omega} = se(\omega) \) if and only if \( L_1 = a_\omega(I_{a_\infty}) \).

**Am-\( \infty \) stability**, the analog of am-stability, is defined for nonzero ideals by any of the following equivalent conditions.

**Corollary 4.10.** Let \( I \neq \{0\} \) be an ideal. The following are equivalent.

(i) \( I = a_\infty I \)

(ii) \( I \cap L_1 = I_{a_\omega} \)

(iii) \( I \subset L_1 \) and \( I = I_{a_\infty} \)

**Proof.**

(i) \( \Rightarrow \) (ii) Since \( I = a_\infty I \subset L_1 \), \( I = I \cap L_1 \subset I_{a_\infty} \) by Proposition 4.8(i') and the reverse inclusion follows by Proposition 4.8(i).

(ii) \( \Rightarrow \) (iii) If \( I \not\subset L_1 \), by Lemma 4.7, \( I_{a_\infty} = sc(\omega) \not\subset L_1 \), against (ii).

(iii) \( \Rightarrow \) (i) One has \( I = I \cap L_1 \subset a_\infty(I_{a_\infty}) = a_\infty I \subset I \) by Proposition 4.8(i') and (i). \hfill \( \square \)

**Definition 4.11.** An ideal \( I \neq \{0\} \) is called am-stable at infinity (or am-\( \infty \) stable) if \( I = a_\infty I \). A sequence \( \xi \in (l]^1* \) is called regular at infinity (\( \infty \)-regular for short) if \( (\xi) = a_\infty(\xi) \).

Therefore, \( (\xi) \) is \( \infty \)-regular if and only if \( (\xi) = (\xi_{a_\infty}) \) by Corollary 4.10 and Lemma 4.7, if and only if \( \xi_{a_\infty} = O(D_m \xi) \) for some \( m \in \mathbb{N} \) by Corollary 3.3 (cf. Corollary 5.6(c)), and surprisingly and more simply, if and only if \( \xi_{a_\infty} = O(\xi) \) (see Theorem 4.12 below). The notion of regularity at infinity for summable sequences is an analog of the usual notion of regularity of nonsummable sequences that was used extensively in [16] and that plays a key role also in Varga’s construction of positive traces on principal ideals [32].

Several characterizations of regular sequences in the am-case have analogs in the am-\( \infty \) case (Theorem 4.12 below), although the proofs have to contend with the problem that \( \xi_{a_\infty} \) may not satisfy the \( \Delta_{1/2} \) condition or, equivalently (Corollary 4.4), that \( \xi \) may not be \( O(\xi_{a_\infty}) \).
For convenience we recall the definition of the Matuszewska indices \( \alpha(\xi) \) and \( \beta(\xi) \) for a monotonic sequence \( \xi \) ([13, Section 2.4]):

\[
\alpha(\xi) := \lim_{n} \frac{\log \xi_{n}}{\log n} = \inf_{n \geq 2} \frac{\log \xi_{n}}{\log n} \quad \text{and} \quad \beta(\xi) := \lim_{n} \frac{\log \xi_{n}}{\log n} = \sup_{n \geq 2} \frac{\log \xi_{n}}{\log n}
\]

where \( \xi_{n} := \sup_{k} \frac{\xi_{k}}{\xi_{n}} \) and \( \xi_{n} := \inf_{k} \frac{\xi_{k}}{\xi_{n}} \). It can be shown that

\[
\alpha(\xi) = \inf \{ \gamma : \exists C > 0 \text{ such that } \xi_{n} \leq C \left( \frac{n}{m} \right)^{\gamma} \xi_{m} \text{ for all } n \geq m \}
\]

\[
\beta(\xi) = \sup \{ \gamma : \exists C > 0 \text{ such that } \xi_{n} \leq C \left( \frac{n}{m} \right)^{\gamma} \xi_{m} \text{ for all } n \geq m \}
\]

The above inequalities characterizing the Matuszewska indices are the discrete analog of the Potter type inequalities in the theory of functions of regular and \( O \)-regular variation (cf. [5, Proposition 2.2.1]), and were linked to regularity of \( c_{0}^{*} \)-sequences in [13, Theorem 3.10], where it was proven that a sequence \( \xi \in c_{0}^{*} \) is regular if and only if \( \beta(\xi) > -1 \) if and only if \( \xi_{a} \) is regular. As indicated in [13, Remark 3.11], the equivalence of \( \xi \) regularity and \( \xi_{a} \) regularity is also implicit in the work of Varga [32, Theorem IRR].

**Theorem 4.12.** If \( \xi \in (\ell^{1})^{*} \), the following conditions are equivalent.

(i) \( \xi \) is \( \infty \)-regular.
(ii) \( \xi_{a} = 0(\xi) \)
(iii) \( \alpha(\xi) < -1 \), i.e., there are constants \( C > 0 \) and \( p > 1 \) for which \( \xi_{n} \leq C \left( \frac{m}{n} \right)^{p} \xi_{m} \) for all integers \( n \geq m \).
(iv) \( \xi_{a} = \infty \)-regular.
(v) \( \inf_{n} \frac{\xi_{a}(\xi)}{\xi_{kn}} > k \) for some integer \( k > 1 \)
(v') \( \inf_{n} \frac{\xi_{a}(\xi)}{\xi_{kn}} > k \) for all integers \( k > 1 \)
(v'') \( \inf_{n} \frac{\xi_{a}(\xi)}{\xi_{kn}} > 0 \) for all integers \( k > 1 \)
(v''') \( \inf_{n} \frac{\xi_{a}(\xi)}{\xi_{kn}} > 0 \) for some integer \( k > 1 \)
(vi) \( \sup_{k} \inf_{n} \frac{\xi_{a}(\xi)}{\xi_{kn}} = \infty \)

**Proof.**

(i) \( \Rightarrow \) (ii) Assume that \( \xi \) is regular at infinity, that is, \( (\xi) = (\xi) = a_{\infty}(\xi) \). Then \( (\xi) = (\xi) = (\xi) = (\xi) \) by Corollary 4.10 and Lemma 4.7 and therefore \( \xi_{a} \leq MD_{m} \xi \) for some \( m \in \mathbb{N} \) and \( M > 0 \). In particular, \( (\xi_{a})_{mn} \leq M \xi_{n} \) for all \( n \). The case \( m = 1 \) is

(ii). If \( m > 1 \) then

\[
(\xi_{a})_{mn} = \frac{1}{mn} \sum_{m+1}^{\infty} \xi_{i} = \frac{1}{mn} \left\{ \sum_{m+1}^{m^2n} \xi_{i} + \sum_{m^2n+1}^{m^3n} \xi_{i} + \sum_{m^3n+1}^{m^4n} \xi_{i} + \cdots \right\}
\]

\[
\geq \frac{1}{mn} \left\{ (m-1)mn \xi_{m^2n} + (m-1)m^2n \xi_{m^3n} + (m-1)m^3n \xi_{m^4n} + \cdots \right\}
\]

\[
= \frac{m-1}{m^2} \sum_{k=2}^{\infty} m^k \xi_{m^kn}.
\]
Thus \( \frac{m-1}{m^2} \sum_{k=2}^{\infty} m^k \xi_{m^k n} \leq M \xi_n \) for all \( n \) and hence, by substituting here \( mn \) for \( n \),

\[
\frac{m-1}{m^3} \sum_{k=3}^{\infty} m^k \xi_{m^k n} \leq M \xi_{mn}.
\]

On the other hand, the same formula for \( (\xi_{a_n})_{mn} \) yields

\[
(\xi_{a_n})_{mn} \leq \frac{1}{mn} \left\{ (m-1)mn \xi_{mn} + (m-1)m^2 n \xi_{m^2 n} + (m-1)m^3 n \xi_{m^3 n} + \cdots \right\}
\]

\[
= \frac{m-1}{m} (m \xi_{mn} + m^2 \xi_{m^2 n}) + \frac{m-1}{m} \sum_{k=3}^{\infty} m^k \xi_{m^k n}
\]

\[
\leq \frac{m-1}{m} (m + m^2) \xi_{mn} + m^2 M \xi_{mn} = M' \xi_{mn}.
\]

From this, since for each \( j \in \mathbb{N} \), \( j = mn - p \) for some \( n \in \mathbb{N} \) and some \( 0 \leq p \leq m - 1 \), one obtains

\[
(\xi_{a_n})_j = \frac{1}{mn - p} \left\{ \xi_{mn - p + 1} + \xi_{mn - p + 2} + \cdots + \xi_{mn} + \sum_{i=mn+1}^{\infty} \xi_i \right\}
\]

\[
\leq \frac{p}{mn - p} \xi_{mn - p} + \frac{mn}{mn - p} (\xi_{a_n})_{mn}
\]

\[
\leq \frac{p}{mn - p} \xi_{mn - p} + \frac{mn}{mn - p} M' \xi_{mn}
\]

\[
\leq (\frac{p}{mn - p} + \frac{mn}{mn - p} M') \xi_{mn - p}
\]

\[
\leq (m - 1 + mM') \xi_j,
\]

which concludes the proof.

(ii) \( \Rightarrow \) (i) Obvious from remarks following Definition 4.11.

(ii) \( \Rightarrow \) (iii) Let \( \xi_{a_n} \leq M \xi \) for some \( M > 0 \) and without loss of generality assume that \( \xi_n > 0 \) for all \( n \). From the basic identity

\[
(n - 1)(\xi_{a_n})_{n-1} = \xi_n + n(\xi_{a_n})_n
\]

follows the recurrence

\[
(\xi_{a_n})_n = \frac{n-1}{n}(\xi_{a_n})_{n-1}
\]

and hence for all \( n > m \geq 1 \),

\[
(\xi_{a_n})_n = \frac{m}{n} \prod_{j=m+1}^{n} \left( 1 + \frac{1}{j} (\xi_{a_n})_j \right) (\xi_{a_n})_m
\]

\[
\leq \frac{m}{n} \prod_{j=m+1}^{n} \left( 1 + \frac{1}{Mj} \right) (\xi_{a_n})_m
\]

\[
= \frac{m}{n} e^{-\sum_{j=m+1}^{n} \log \left( 1 + \frac{1}{Mj} \right)} (\xi_{a_n})_m.
\]

Let \( N \) be the smallest integer larger than or equal to \( \frac{1}{M} \), \( p := 1 + \frac{1}{M} \) and set \( K := Ne^{\left( \frac{\log 2}{M} - \frac{1}{2M^2} \right)} \). If \( m \geq N \) then \( Mj > 1 \) for all \( j \geq m + 1 \) and hence
log \left( 1 + \frac{1}{Mj} \right) > \frac{1}{Mj} - \frac{1}{2M^2j^2}. \quad \text{Thus if } n > m \geq N,
\begin{align*}
(\xi_{a_\infty})_n &\leq \frac{m}{n} e^{-\sum_{j=m+1}^{n} \frac{1}{2Mj^2}} (\xi_{a_\infty})_m \\
&\leq \frac{m}{n} e^{-\frac{1}{M} \log \frac{m}{n} + \frac{m}{2M}} (\xi_{a_\infty})_m \\
&\leq e^{\log \frac{2}{M} + \frac{1}{2M^2}} (\frac{m}{n})^p (\xi_{a_\infty})_m.
\end{align*}

If \( n > N > m \), the above inequality implies
\[(\xi_{a_\infty})_n \leq e^{\log \frac{2}{M} + \frac{1}{2M^2}} (\frac{N}{n})^p (\xi_{a_\infty})_N \leq K(\frac{m}{n})^p (\xi_{a_\infty})_m.\]

If \( N \geq n \geq m \) then \( K \geq N^p \geq (\frac{m}{n})^p \) and hence
\[(\xi_{a_\infty})_n \leq (\xi_{a_\infty})_m \leq K(\frac{m}{n})^p (\xi_{a_\infty})_m.\]

Thus \( (\xi_{a_\infty})_n \leq K(\frac{m}{n})^p (\xi_{a_\infty})_m \) for all \( n \geq m \), hence \( (\xi_{a_\infty})_n \leq MK(\frac{m}{n})^p \xi_m \).

From Lemma \( \text{[iv]} \), \( \xi_{2n} \leq (\xi_{a_\infty})_n \) so
\[\xi_{2n} \leq MK(\frac{m}{n})^p \xi_m\]
for all \( n \geq m \). Set \( C = 3^p MK \) and let \( k \geq 2m \). If \( k \) is even, then
\[\xi_k \leq MK(\frac{m}{k/2})^p \xi_m \leq C(\frac{m}{k})^p \xi_m,\]
while if \( k \) is odd then
\[\xi_k \leq \xi_{n-1} \leq MK(\frac{m}{(k-1)/2})^p \xi_m \leq 3^p MK(\frac{m}{k})^p \xi_m = C(\frac{m}{k})^p \xi_m.\]

Finally, if \( m \leq k < 2m \), \( \xi_k \leq \xi_m \leq 2^p (\frac{m}{k})^p \xi_m \leq C(\frac{m}{k})^p \xi_m \) since \( MK > M2^{1/M} > 1 \).

(iii) \( \Rightarrow \) (ii) A direct computation shows that \( (\xi_{a_\infty})_n \leq \frac{C}{p-1} \xi_n \).

(ii) \( \Rightarrow \) (iv) If \( \xi_{a_\infty} \leq M \xi \), then \( \xi_{a_\infty}^n \leq M(\xi_{a_\infty})^n \), hence by the equivalence of (i) and (ii), \( \xi_{a_\infty} \) is \( \infty \)-regular.

(iv) \( \Rightarrow \) (ii) Since (i) and (iii) are equivalent, there exists \( p > 1, C > 0 \) so
\[(\xi_{a_\infty})_n \leq C(\frac{m}{n})^p (\xi_{a_\infty})_m \text{ for all } n \geq m.\]

Thus \( (\xi_{a_\infty})_{km} \leq (\frac{1}{k})^q (\xi_{a_\infty})_m \) for some \( q > 1 \) and integer \( k > 1 \), and hence \( \sum_{\xi_{km+1}}^{\xi_{km}} \leq (\frac{1}{k})^{q-1} \Omega_{k+1} \) \( \xi_i \) for all \( m \). But then \( (1 - (\frac{1}{k})^{q-1}) \sum_{\xi_{m+1}}^{\xi_m} \leq \sum_{\xi_{m+1}}^{\xi_m} \xi_i \leq (k-1) m \xi_m \) and hence (ii) holds.

(ii) \( \Rightarrow \) (v') \( \Rightarrow \) (v'') \( \Rightarrow \) (v''') For every \( k > 1 \),
\[(k-1)n \xi_{kn} \leq \sum_{\xi_{j=n+1}}^{\xi_{kn}} \xi_j \leq (k-1)n \xi_n \quad \text{for all } n,
\]

hence
\[1 + \frac{(k-1) \xi_{kn}}{k(\xi_{a_\infty})_{kn}} \leq \frac{\sum_{\xi_{j=n+1}}^{\xi_{kn}} \xi_j}{\sum_{\xi_{j=n+1}}^{\xi_{kn}} \xi_j} \leq 1 + \frac{(k-1) \xi_n}{k(\xi_{a_\infty})_{kn}}\]
or, equivalently,
\[(k-1) \frac{\xi_{kn}}{(\xi_{a_\infty})_{kn}} \leq \frac{(\xi_{a_\infty})_n}{(\xi_{a_\infty})_{kn}} - k \leq (k-1) \frac{\xi_n}{(\xi_{a_\infty})_{kn}}.\]
Thus, for every $k > 1$, 
\[
\xi_{a\infty} = O(\xi) \Rightarrow \inf_n \frac{\xi_{kn}}{\xi_{a\infty})_n} > 0 \Rightarrow \inf_n \frac{(\xi_{a\infty})_n}{(\xi_{a\infty})_n} > k \Rightarrow \inf_n \frac{\xi_n}{(\xi_{a\infty})_n} > 0.
\]

(v') $\Rightarrow$ (v) $\Rightarrow$ (v'') $\Rightarrow$ (i) The first implication is obvious and the second follows from the same double inequality we used above. If (iv'') holds, i.e., for some $M > 0$ and $k > 1$, $(\xi_{a\infty})_n \leq M \xi_n$ for all $n$, then for $j \in \mathbb{N}$, $j = kn - p$ with $0 \leq p \leq k - 1$ and 
\[
\xi_{a\infty})_j = \frac{1}{kn-p}(\xi_{kn-p+1} + \cdots + \xi_{kn} + kn(\xi_{a\infty})_n)
\]
\[
\leq \frac{1}{kn-p}(p\xi_n + knM\xi_n)
\]
\[
\leq (k-1 + kM)\xi_n
\]
\[
= (k-1 + kM)(D_k\xi)_j.
\]
Thus $\xi_{a\infty} = O(D_k\xi)$, that is, $\xi$ is $\infty$-regular.

(v') $\Rightarrow$ (vi) $\sup_k \inf_n \frac{(\xi_{a\infty})_n}{(\xi_{a\infty})_n} \geq 1$ since $n(\xi_{a\infty})_n \geq kn(\xi_{a\infty})_n$ for all $n, k$. Suppose $\sup_k \inf_n \frac{(\xi_{a\infty})_n}{(\xi_{a\infty})_n} = M < \infty$. Then $M = 1$ since otherwise, for some $k$, $\inf_n \frac{(\xi_{a\infty})_n}{(\xi_{a\infty})_n} \geq \sqrt{M}$ and hence $\inf_n \frac{(\xi_{a\infty})_n}{(\xi_{a\infty})_n} \geq \inf_n \frac{(\xi_{a\infty})_n}{(\xi_{a\infty})_n} \inf_n \frac{(\xi_{a\infty})_n}{(\xi_{a\infty})_n} > M$ against the definition of $M$. But $M = 1$.

(vi) $\Rightarrow$ (v) Obvious.

\[\square\]

Remark 4.13.

(a) The Potter type inequality in (iii) (cf. [3] Proposition 2.2.1, and see also [2] and [13] Theorem 3.10, Remark 3.11) was shown by Kalton in [25] Corollary 7) to be necessary and sufficient for (\xi) to support a unique separately continuous trace. By Theorem 4.12 and Theorem 6.6 below this condition is also necessary and sufficient for (\xi) to support a unique trace, which in this case coincides with $Tr$ and hence is separately continuous.

(b) In the course of the proof of (ii) $\Rightarrow$ (iii) we have obtained that if $\xi$ is $\infty$-regular and if $\xi_{a\infty} \leq M \xi$, then $\alpha(\xi) \leq -\left(1 + \frac{1}{M}\right)$. Hence $\alpha(\xi) \leq -1 - \inf \xi_{a\infty}$.

(c) The proof of (iv) $\Rightarrow$ (ii) is an adaptation of the proof in the am-case in [13] Theorem 3.10: (c)' $\Rightarrow$ (a)]. Conditions (v)-(v'') and their proofs are am-$\infty$ analogues of the characterizations of regular sequences given by Varga in [32] Lemma 1]. Albeverio et al. in [1] used conditions equivalent to the negation of (v) and (vi) to define “generalized eccentric” operators (for the trace class case) for which their main result showed the existence of positive singular traces.

(d) Condition (ii) strengthens [13] Corollary 5.19 and [39] Corollary 5.6] by eliminating the need for ampliations, i.e., replacing the condition $\xi_{a\infty} = O(D_m\xi)$ for some $m$ by the condition $\xi_{a\infty} = O(\xi)$.

(d) Whereas regular sequences are those for which $\xi \cong \xi_{a}$; this is not true for the am-$\infty$ case. In fact, by Corollary 4.14(ii), $\xi \cong \xi_{a\infty}$ if and only if $\xi$ is $\infty$-regular (i.e., $\xi = (\xi_{a\infty})$) and satisfies the $\Delta_{1/2}$-condition. And as Example 4.5(ii) shows, $\xi$ can be regular at infinity while $\xi \not\cong \xi_{a\infty}$.
The equivalence of (ii) and (iii) is the am-∞ analog of [13, Theorem 3.10(a),(b),(b)']. We give a direct proof of the am-case that provides also a lower bound for $\beta(\xi)$.

**Proposition 4.14.** A sequence $\xi \in c_0$ is regular, i.e., $\xi_a = O(\xi)$, if and only if there are constants $C > 0$ and $0 < p < 1$ for which $\xi_n \geq C(\frac{m}{n})^{p} \xi_m$ for all $n \geq m$, and then $\beta(\xi) \geq -1 + \inf \frac{\xi}{\xi_a}$.

**Proof.** A simple computation shows that if $\xi_n \geq C(\frac{m}{n})^{p} \xi_m$ for all $n \geq m$, then $\xi_a \leq \frac{1}{(1-p)^{C}} \xi$.

Conversely, assume $\xi \neq 0$ and $\xi_a = O(\xi)$, i.e., $\xi_a \leq M\xi$ for some $M > 1$. The identity $n(\xi_a)_n = \xi_n + (n-1)(\xi_a)_{n-1}$ implies the recurrence

$$
(\xi_a)_n = \frac{n-1}{n}(\xi)_n(\xi_a)_{n-1}
$$

and hence

$$
(\xi_a)_n = \frac{m}{\prod_{j=m+1}^{n}(1 - \frac{1}{\xi_a}_j)}(\xi_a)_m
$$

for all $n > m$. Then

$$
\xi_n = \frac{m}{\prod_{j=m+1}^{n}(1 - \frac{1}{\xi_a}_j)}(\xi_a)_m \geq \frac{m}{\prod_{j=m+1}^{n}(1 - \frac{1}{\xi_a})} \xi_m
$$

$$
= \frac{m}{Mn} e^{-\sum_{j=m+1}^{n} \log(1 - \frac{1}{\xi_a})} \xi_m \geq \frac{m}{Mn} e^{\sum_{j=m+1}^{n} \frac{1}{\xi_a}} \xi_m
$$

$$
\geq \frac{m}{Mn} e^\left(\frac{1}{\log(\frac{m}{n})}\right) \xi_m = \frac{1}{M2^{\frac{1}{\log(\frac{m}{n})}}} \xi_m.
$$

And from the inequality characterizing the Matuszewska index $\beta(\xi)$ mentioned prior to Theorem 4.12, $\beta(\xi) \geq -1 + \frac{1}{M}$, from which it follows that $\beta(\xi) \geq -1 + \inf \frac{\xi}{\xi_a}$. □

For the readers’ convenience, we summarize the known relations between the sequence properties most frequently considered in this paper, the Matuszewska index $\beta$, and the new relations to the analogous properties for Matuszewska’s index $\alpha$ developed here.

**Corollary 4.15.** Let $\xi \in c_0^\ast$. Then $-\infty \leq \beta(\xi) \leq \alpha(\xi) \leq 0$ and

(i) $\xi$ satisfies the $\Delta_{1/2}$-condition if and only if $\beta(\xi) > -\infty$, i.e., if and only if there are constants $C > 0$ and $p > 0$ for which $\xi_n \geq C(\frac{m}{n})^{p} \xi_m$ for all $n \geq m$, and if only if $\xi^e$ is regular for some $e > 0$. ([13, 2.4 (22), 2.23, Theorem 3.5])

(ii) If $\xi < \eta_a$ for some $\eta \in c_0^\ast$, then $\beta(\xi) \geq -1$ (since for $n \geq m$, $\frac{(\xi_a)_n}{(\xi_a)_n} \geq \frac{m}{n}$).

(iii) $\xi$ is regular if and only if $\beta(\xi) > -1$. ([13, Theorem 3.10])

(iv) $\xi^s$ is regular for every $s > 0$ if and only if $\beta(\xi) = 0$. ([13, Corollary 5.16])

(i') $\xi$ satisfies the condition $\sup \frac{\xi_a}{\xi_n} < 1$ if and only if $\alpha(\xi) < 0$, i.e., if and only if there are constants $C > 0$ and $p > 0$ for which $\xi_n \leq C(\frac{m}{n})^{p} \xi_m$ for all $n \geq m$, and if only if $\xi^e$ is $\infty$-regular for some $e > 0$. (Elementary from the definition and (i))

(ii') If $\xi < \eta_{a\infty}$ for some $\eta \in c_0^\ast$, then $\alpha(\xi) \leq -1$ (since for $n \geq m$, $\frac{\xi_a_{\infty}}{(\xi_a)_{\infty}} \leq \frac{m}{n}$).

(iii') $\xi$ is $\infty$-regular if and only if $\alpha(\xi) < 1$. (Theorem 4.12)

(iv') $\xi^s$ is $\infty$-regular for every $s > 0$ if and only if $\alpha(\xi) = -\infty$. (By (iii').)
In another paper we study lattice properties of am-$\infty$ stable ideals. Among other results there we show that every principal ideal with the exception of the finite rank ideal $F$ contains a am-$\infty$ stable principal ideal strictly larger than $F$ and is contained in an am-stable principal ideal. $F$ is the smallest nonzero am-$\infty$ stable ideal, $K(H)$ is the largest am-stable ideal and there is a largest am-$\infty$ stable ideal $st_{a_{\infty}}(L_1)$ and a smallest am-stable ideal $st^a(L_1)$ (see below). These naturally divide all ideals into the three classes described in the Introduction, namely, the “small ideals” contained in $st_{a_{\infty}}(L_1)$, the “large ideals” containing $st^a(L_1)$, and the “intermediate ideals” that are neither.

**Definition 4.16.** The lower and upper am-stabilizers (resp., am-$\infty$ stabilizers) for an ideal $I$ are:

$$st_a(I) := \bigcap_{m=0}^{\infty} a^m I$$

$$st^a(I) := \bigcup_{m=0}^{\infty} I_0^m$$

$$st_{a_{\infty}}(I) := \bigcap_{m=0}^{\infty} a^m_\infty I \text{ for } I \neq \{0\}$$

$$st^{a_{\infty}}(I) := \bigcup_{m=0}^{\infty} I_0^m_\infty \text{ for } I \subset st_{a_{\infty}}(L_1)$$

It is easy to verify that $st_a(I)$ (resp., $st^a(I)$) is the largest am-stable ideal contained in $I$ (resp., the smallest am-stable ideal containing $I$).

It follows similarly from Proposition 4.8(i) that $st_{a_{\infty}}(I)$ is well-defined and is the largest am-$\infty$ stable ideal contained in $I$.

If $I \subset se(\omega)$, then $\{I_0^m\}$ is an increasing nest of ideals by Proposition 4.8(iv) and hence its union is an ideal and $I \subset (\cup_{m=0}^{\infty} I_0^m_\infty)_{a_{\infty}} = \cup_{m=0}^{\infty} I_0^m_\infty$. If furthermore $I \subset st_{a_{\infty}}(L_1)$, then also $I_0^m_{a_{\infty}} \subset st_{a_{\infty}}(L_1) \subset L_1$ for all $m$, hence $\cup_{m=0}^{\infty} I_0^m_\infty \subset L_1$ and by Corollary 4.19 $st_{a_{\infty}}(L_1)$ is am-$\infty$ stable. Notice that if $I \subset se(\omega)$ but $I \not\subset st_{a_{\infty}}(L_1)$, i.e., $I_0^m \not\subset L_1$ for some $m \geq 0$, then, by Lemma 4.7, $I_0^{m+1} = se(\omega)$ and so $\cup_{m=0}^{\infty} I_0^m_\infty = se(\omega)$ which is not am-$\infty$ stable.

Thus, in particular, $st^a(L_1) = st^a(F) = st^a((\omega))$ is the smallest am-stable ideal and $st_{a_{\infty}}(L_1) = st_{a_{\infty}}(K(H)) = st_{a_{\infty}}((\omega))$ is the largest am-$\infty$ stable ideal.

**Remark 4.17.**

(i) If $I$ is a principal ideal which is not am-stable, then $st^a(I)$ is a strictly increasing nested union of principal ideals. Indeed, $(\xi_a^m) = I_a^m = I_a^{m+1} = (\xi_a^{m+1})$ if $I = (\xi)$ implying that $\xi_a^m$ is regular and hence as recalled before Theorem 4.12, $\xi$ is regular, i.e., $(\xi)$ is am-stable.

(ii) Similarly, if $I \subset st_{a_{\infty}}(L_1)$ is principal and not am-$\infty$ stable, by Theorem 4.12 (the equivalence of (i) and (iv)) and Lemma 4.7, $st^{a_{\infty}}(I)$ is also a strictly increasing nested union of principal ideals. This phenomenon does not even extend to countably generated ideals as Example 5.5 shows by constructing a countably generated ideal $L \subset L_a = L_a^{\infty}$.
The next proposition shows that \(st^a(L_1)\) is the union of principal ideals and that \(st_{a\infty}(L_1)\) is the intersection of Lorentz ideals. Recall from [13 Sections 2.25, 2.27, 4.7] that if \(\pi\) is a positive nondecreasing \(\Delta_2\)-sequence, then \(L(\sigma(\pi))\) is the Lorentz ideal with characteristic set \(\Sigma(L(\sigma(\pi))) := \{\xi \in c_0^* \mid \sum_n \xi_n \pi_n < \infty\}\).

**Proposition 4.18.**

\[
\begin{align*}
(i) \quad st^a(L_1) &= \bigcup_{m=0}^{\infty} (\omega \log^m) \\
(ii) \quad st_{a\infty}(L_1) &= \bigcap_{m=0}^{\infty} L(\sigma(\log^m))
\end{align*}
\]

**Proof.**

(i) This is clear since \(st^a(L_1) = st^a((L_1)_a) = st^a((\omega))\) and \((\omega)_a = (\omega \log^m)\) for every \(m \in \mathbb{N}\).

(ii) \(\xi \in \Sigma(a\infty L(\sigma(\log^m)))\) if and only if \(\xi \in (\ell^1)^*\) and

\[
\sum_{n=1}^{\infty} \left( \sum_{j=n+1}^{\infty} \xi_j \right) \frac{\log^m n}{n} < \infty \text{ if and only if } \sum_{n=1}^{\infty} \xi_n \log^{m+1} n < \infty,
\]

i.e., \(\xi \in \Sigma(L(\sigma(\log^{m+1})))\). Therefore \(a\infty L(\sigma(\log^m)) = L(\sigma(\log^m))\) and hence \(a\infty(L_1) = L(\sigma(\log^m))\). \(\square\)

Thus, if \(\xi \in c_0^*\) is \(\infty\)-regular, then \(\xi \in \Sigma(st_{a\infty}(L_1))\) and hence \(\sum_{n=1}^{\infty} \xi_n \log^m n < \infty\) for every \(m\) (cf. Example 4.5(iv)). Notice also that the proof of (ii) shows in particular that \(a\infty(L_1) = L(\sigma(\log))\). In [20] we prove that \(st^a(L_1)\) and \(st_{a\infty}(L_1)\) are both soft-edged and soft-complemented.

In Section 7 we will need the following analogues of Lemma 3.3 and Proposition 3.4.

**Lemma 4.19.** Let \(I\) be an ideal.

(i) \(sc(a\infty I) = a\infty(sc I)\) when \(I \neq \{0\}\)

(ii) \((seI)_{a\infty} = se(I_{a\infty})\)

**Proof.**

(i) Let \(\eta \in \Sigma(sc(a\infty I))\). Since \(a\infty I \subset L_1\), \(sc(a\infty I) \subset scL_1 = L_1\) and hence \(\eta \in (\ell^1)^*\).

Choose a strictly increasing sequence of positive integers \(n_k\) with \(n_{-1} = n_0 = 0\) for which \(\sum_{n_k}^{n_{k+1}} \eta_j \geq \frac{1}{2} \sum_{n_k}^{n_{k+1}} \eta_j\) for \(k \geq 0\).

For each \(\alpha \in c_0^*\) set \(\alpha_0 := \alpha_1\) and define

\[
\tilde{\alpha}_j := 2\alpha_{n_{k+1}} \quad \text{for } n_k < j \leq n_{k+1} \text{ and } k \geq 0.
\]

Then \(\tilde{\alpha} = < \tilde{\alpha}_j > \in c_0^*\) and for all \(n_k < p \leq n_{k+1}\) and \(k \geq 0\),

\[
\sum_{p}^{\infty} \tilde{\alpha}_j \eta_j \geq \sum_{p}^{n_{k+2}} \tilde{\alpha}_j \eta_j = 2\alpha_{n_{k+1}} \sum_{p}^{n_{k+1}} \eta_j + 2\alpha_{n_k} \sum_{n_{k+1}}^{n_{k+2}} \eta_j
\]

\[
\geq \alpha_{n_{k-1}} \sum_{p}^{n_{k+1}} \eta_j + \alpha_{n_k} \sum_{n_{k+1}+1}^{\infty} \eta_j \geq \alpha_{n_k} \sum_{p}^{\infty} \eta_j.
\]
Thus $\alpha\eta_{a_\infty} \leq (\tilde{\alpha}\eta)_{a_\infty}$. Since $\tilde{\alpha}\eta \in \Sigma(a_\infty I)$ from the definition of $sc$ it follows that $(\tilde{\alpha}\eta)_{a_\infty} \in \Sigma(I)$ and hence that $\eta_{a_\infty} \in \Sigma(scI)$, i.e., $\eta \in \Sigma(a_\infty (scI))$. Hence $sc(a_\infty I) \subset a_\infty (scI)$.

Now let $\eta \in \Sigma(a_\infty (scI))$ and $\alpha \in c^*_o$. Then $\eta_{a_\infty} \in \Sigma(scI)$ and hence $\alpha\eta_{a_\infty} \in \Sigma(I)$. Since $(\alpha\eta)_{a_\infty} \leq \alpha\eta_{a_\infty}$, also $(\alpha\eta)_{a_\infty} \in \Sigma(I)$, i.e., $\alpha\eta \in \Sigma(a_\infty I)$ so $\eta \in \Sigma(sc(a_\infty I))$, which yields the set equality.

(ii) Assume first that $I \not\in \mathcal{L}_1$. Since $\mathcal{L}_1$ is soft-complemented, also $seI \not\in \mathcal{L}_1$ since otherwise $I \subset scI = sc \subset sc\mathcal{L}_1 = \mathcal{L}_1$. But then, from Lemma 4.10, it follows that $(seI)_{a_\infty} = sc(\omega) \subset scI = sc(\omega)$, hence $se(I_{a_\infty}) = sc(\omega) = (seI)_{a_\infty}$.

Assume now that $I \in \mathcal{L}_1$. If $\xi \in \Sigma((seI)_{a_\infty})$ then $\xi \leq \rho_{a_\infty}$ for some $\rho \in \Sigma(scI)$, i.e., $\rho \leq \alpha\eta$ for some $\alpha \in c^*_o$ and $\eta \in \Sigma(I)$. But then $\xi \leq (\alpha\eta)_{a_\infty} \leq \alpha\eta_{a_\infty}$. By definition, $\alpha\eta_{a_\infty} \in \Sigma(sc(I_{a_\infty}))$, hence $(seI)_{a_\infty} \subset sc(I_{a_\infty})$. For the reverse inclusion, let $\xi \in \Sigma(sc(I_{a_\infty}))$ hence $\xi \leq \alpha\rho$ for some $\alpha \in c^*_o$ and $\rho \in \Sigma(I_{a_\infty})$, that is, $\rho \leq \eta_{a_\infty}$ for some $\eta \in \Sigma(I)$. As in the proof of part (i), $\xi \leq \alpha\eta_{a_\infty} \leq (\tilde{\alpha}\eta)_{a_\infty}$ for some $\tilde{\alpha} \in c^*_o$. But $\tilde{\alpha}\eta \in \Sigma(scI)$ and therefore $\xi \in \Sigma((seI)_{a_\infty})$, which yields the set equality. \qed

**Proposition 4.20.** The following are equivalent for ideals $I \neq \{0\}$.

(i) $seI$ is am-$\infty$ stable.

(ii) $scI$ is am-$\infty$ stable.

(iii) $seI \subset \alpha_{a_\infty}I$

(iii’) $\omega \notin \Sigma(I)$ and $seI \subset F + [I, B(H)]$.

(iv) $\omega \notin \Sigma(scI)$ and $scI \supset I_{a_\infty}$

**Proof.**

(i) $\Rightarrow$ (iii) Since $seI \subset I$ and the pre-arithmetic mean at infinity is inclusion preserving, $seI = a_{a_\infty}(seI) \subset a_{a_\infty}I$.

(iii) $\Rightarrow$ (ii) $scI = sca_{a_\infty}I = a_{a_\infty}(scI) \subset scI$ where the first equality is true for all ideals (recall comment preceding Remark 3.2), the second equality follows from Lemma 4.19(i) and the last inclusion from Proposition 4.8(i).

(ii) $\Rightarrow$ (iv) By Corollary 4.10 $seI \subset \mathcal{L}_1$ so $\omega \notin \Sigma(scI)$. Also $scI = (scI)_{a_\infty} \supset I_{a_\infty}$.

(iv) $\Rightarrow$ (i) $I \subset \mathcal{L}_1$ because otherwise $se(\omega) = I_{a_\infty} \subset scI$ by Lemma 4.7 and thus $scI = sc(sc(\omega)) \subset scI$, against the hypothesis. But then $seI \subset \mathcal{L}_1$ and hence $scI \subset (seI)_{a_\infty}$ from Proposition 4.8(i’). For the reverse inclusion, by Lemma 4.19(ii), $(seI)_{a_\infty} = se(I_{a_\infty}) \subset sc(scI) = seI$, and so $(seI)_{a_\infty} = seI$. The conclusion now follows from Corollary 4.10.

(iii) $\Rightarrow$ (iii’) Since (iii) implies (iv), $\omega \notin \Sigma(I)$ and by Corollary 6.2(i) $seI \subset a_{a_\infty}I = \overline{\text{span} \{a_{a_\infty}I\}^+} \subset \overline{\text{span} \{F + [I, B(H)]\}^+} \subset F + [I, B(H)]$.

(iii’) $\Rightarrow$ (iii) Again by Corollary 6.2(ii), $(seI)^+ \subset (F + [I, B(H)])^+ = (a_{a_\infty}I)^+$, hence $seI \subset a_{a_\infty}I$. \qed

**Remark 4.21.** Analogous to Remark 3.3, the se and sc operations preserve am-$\infty$ stability by Lemma 4.19(i) and Proposition 4.20. However, Example 4.22 below shows that $seI$ and $scI$ can be am-$\infty$ stable while $I$ is not.
Example 4.22. We construct an ideal \( I \) such that \( seI = se(\omega^2) \) and hence \( scI = (\omega^2) \) are am-\( \infty \) stable but \( I \) is not am-\( \infty \) stable.

Indeed, let \( m_k = (k!)^2 \) and define \( \eta_j = \frac{1}{m_k^j} \) for \( m_{k-1} < j \leq m_k \). Then \( \eta \in c_0^*, \eta \leq \omega^2 \) but \( \eta \neq o(\omega^2) \). Set \( I = se(\omega^2) + (\eta) \). Then \( seI = se(\omega^2) \) and hence \( scI = (\omega^2) \). By Example 4.20(i), \( \omega^2 \) is \( \infty \)-regular, i.e., \( (\omega^2) \) is am-\( \infty \) stable and thus so are \( seI \) and \( scI \). However \( I \) is not am-\( \infty \) stable. To prove this by contradiction, assume that it is. Then \( \eta_{a_\infty} \in \Sigma(I) \), i.e., there is an \( \alpha \in c_0^*, M > 0 \), and \( p \in \mathbb{N} \) such that \( \eta_{a_\infty} \leq \alpha \omega^2 + MD_p \eta \).

Without loss of generality assume that \( \alpha_j = \epsilon_k \) for \( m_{k-1} < j \leq m_k \). For every \( m_{k-1} < n \leq m_k \),

\[
(\eta_{a_\infty})_n > \frac{1}{n} \sum_{j=n+1}^{m_k} \frac{1}{m_k^2} = \frac{m_k - n}{nm_k^2}.
\]

In particular, for \( k > p \) by choosing \( n = km_{k-1} = \frac{m_k}{k} \) we have

\[
\frac{k - 1}{m_k^2} < \epsilon_k \frac{k^2}{m_k^2} + M(D_p \eta)_{km_{k-1}} = \epsilon_k \frac{k^2}{m_k^2} + M \frac{1}{m_k^2}.
\]

This implies \( \epsilon_k > \frac{k - 1}{m_k^2} > \frac{1}{2k} \) for \( k \) large enough, in which case then \( 2\epsilon_k m_k > km_{k-1} \).

Now by choosing \( n = [2\epsilon_k m_k] \) and \( k \) large enough to insure that \( \epsilon_k \leq \frac{1}{2} \), we have \( km_{k-1} \leq n \leq m_k \) and hence

\[
\frac{m_k - n}{nm_k^2} < (\eta_{a_\infty})_n \leq \frac{\epsilon_k}{n^2} + (D_p \eta)_n = \frac{\epsilon_k}{n^2} + \frac{M}{m_k^2}.
\]

Then

\[
M + 1 \geq \frac{m_k}{n} - \frac{\epsilon_k m_k^2}{n^2} \geq \frac{1}{2\epsilon_k} - \frac{\epsilon_k m_k^2}{(2\epsilon_k m_k - 1)^2} = \frac{1}{\epsilon_k} \left( 1 - \frac{1}{(2 - \epsilon_k m_k)^2} \right)
\]

which is a contradiction since \( \epsilon_k m_k \to \infty \) and \( \epsilon_k \to 0 \).

5. Nonsingular traces and applications to elementary operators

It is well-known that the restriction of a trace on an ideal \( I \) to the ideal \( F \) of finite rank operators must be a (possibly zero) scalar multiple of the standard trace \( Tr \).

Definition 5.1. A trace on an ideal that vanishes on \( F \) is called singular, and nonsingular otherwise.

Dixmier [11] provided the first example of a (positive) singular trace. Its domain is the am-closure, \((\eta)^- = a(\eta)_a\), of a principal ideal \((\eta) \subset se(\eta)_a\).

Theorem 2.2 yields a complete characterization of ideals that support a nonsingular trace, namely, those ideals that do not contain \( \text{diag} \omega \) (cf. [13] Introduction, Application 3 of Theorem 5.6) and also [14]). For the reader’s convenience this argument is presented and generalized in Proposition 5.3 below. To prove it we first need another simple consequence of Theorem 2.2.

Lemma 5.2. Let \( I \neq \{0\} \) be an ideal for which \( \omega \notin \Sigma(I) \).

(i) \( \mathcal{L}_1 \cap [I,B(H)] \) \( \subset \) \( \{X \in \mathcal{L}_1 \mid Tr \; X = 0\} \)

(ii) \( \text{dim} \; \frac{F(I,B(H))}{[I,B(H)]} = 1 \)
Proof.

(i) Since the subspace $\mathcal{L}_1 \cap [I, B(H)]$ is the span of its selfadjoint elements, consider $X = X^* \in \mathcal{L}_1 \cap [I, B(H)]$. Then $\lambda(X)_a \in S(I)$ by Theorem 2.2. Then if $\sum_{j=1}^{\infty} \lambda(X)_j = \text{Tr} X \neq 0$, it would follow that $|\lambda(X)_a| > \omega$ and hence, by the hereditarily of $I^+$, $\omega \in \Sigma(I)$, against the hypothesis.

(ii) Fix a rank one projection $P$. Then $\lambda(P)_a = \omega$ and so $P \notin [I, B(H)]$ by Theorem 2.2. For each $X \in F + [I, B(H)]$ choose $T \in F$ for which $X - T \in [I, B(H)]$. As $T - (\text{Tr} T)P \in [F, B(H)] \subset [I, B(H)]$ from the well-known fact that a finite complex matrix is a commutator if and only if it has zero trace (cf. [18, Discussion of Problem 230]), one obtains $X - (\text{Tr} T)P \in [I, B(H)]$. Thus

$$F + [I, B(H)] = \{\lambda P + [I, B(H)] \mid \lambda \in \mathbb{C}\}.$$ 

\[\square\]

**Proposition 5.3.** Let $I$ and $J$ be ideals and let $\tau$ be a trace on $J$. Then $\tau$ has a trace extension to $I + J$ if and only if

$$J \cap [I, B(H)] \subset \{ X \in J \mid \tau(X) = 0 \}.$$ 

Moreover, the extension is unique if and only if $I \subset J + [I, B(H)]$.

In particular, $\omega \notin \Sigma(I)$ if and only if $\text{Tr}$ extends from $\mathcal{L}_1$ to $\mathcal{L}_1 + I$ if and only if $\text{Tr}$ extends from $F$ to $I$.

**Proof.** Assume that a trace $\tau$ on $J$ has a trace extension $\tilde{\tau}$ to $I + J$ and that $X \in J \cap [I, B(H)]$. Then $X \in [I + J, B(H)]$ and hence $\tau(X) = \tilde{\tau}(X) = 0$ since every trace on $I + J$ must vanish on the commutator space of $I + J$.

Conversely, assume that $J \cap [I, B(H)] \subset \{ X \in J \mid \tau(X) = 0 \}$. For $X \in J + [I, B(H)]$ choose $Y \in J$ for which $X - Y \in [I, B(H)]$ and define $\tau'(X) := \tau(Y)$. As is easy to verify, $\tau'$ is a well-defined linear functional on $J + [I, B(H)]$, it extends $\tau$, it vanishes on $[I, B(H)]$ and hence also on $[I + J, B(H)] = [I, B(H)] + [J, B(H)]$, and it is the unique linear extension of $\tau$ to $J + [I, B(H)]$ that vanishes on $[I, B(H)]$.

If $I + J \neq J + [I, B(H)]$, use a Hamel basis argument to further extend $\tau'$ to a linear functional $\tau''$ on $I + J$, and this extension is never unique. Since $\tau''$ vanishes on $[I + J, B(H)]$ it is a trace on $I + J$.

The case for extending $\text{Tr}$ from $\mathcal{L}_1$ or $F$, when $\omega \notin \Sigma(I)$, follows from Lemma 5.2(i). Conversely, if $\omega \in \Sigma(I)$, then $\mathcal{L}_1 \subset I$ and by Theorem 2.2, $\mathcal{L}_1^+ \subset [I, B(H)]$, whence $\mathcal{L}_1 \subset [I, B(H)]$. Thus all traces on $I$ vanish on $\mathcal{L}_1$, i.e., $\text{Tr}$ cannot extend from $F$ or $\mathcal{L}_1$ to $I$. \[\square\]

A simple consequence of this is that all traces on $J$ extend to $I + J$ if and only if $J \cap [I, B(H)] \subset [J, B(H)]$ since, as is elementary to show,

$$[J, B(H)] = \bigcap \{ \{ X \in J \mid \tau(X) = 0 \} \mid \tau \text{ is a trace on } J \}.$$ 

**Remark 5.4.**

(i) A routine argument shows that for any ideal $J$ and trace $\tau$ on $J$, the collection of the ideals to which $\tau$ can be extended, i.e. the ideals $I \supset J$ for which

$$J \cap [I, B(H)] \subset \{ X \in J \mid \tau(X) = 0 \},$$

is closed under directed unions and hence it always has maximal elements. Because this collection is hereditary with respect to inclusion, it is closed under addition if and only if it has a unique maximal element. That this may not be the case is easy to show for \( \tau = \text{Tr} \) and \( J = F \) by constructing two principal ideals \( I_1 \) and \( I_2 \) with \( I_1 \neq I_2 \), \( I_1 + I_2 = (\omega) \), but \( I_i \neq (\omega) \) for \( i = 1, 2 \).

(ii) If a trace \( \tau \) on and ideal \( J \) has extensions \( \tau_i \) to the ideals \( I_1 \subset I_2 \), there is no reason for \( \tau_1 \) to have an extension to \( I_2 \). For instance, again in the case of \( \tau = \text{Tr} \), \( J = F \), and \( \omega \notin \Sigma(I) \), there is a unique trace on \( I \) if and only if \( I \) is am-\( \infty \) stable (see Theorem 6.6 below). Thus if \( I_1 \) is not am-\( \infty \) stable but is contained in an am-\( \infty \) stable ideal \( I_2 \), then all but one of the traces on \( I_1 \) do not further extend to \( I_2 \).

(iii) By Lemma 6.2(i), the set equality holds always in

\[
J \cap [I, B(H)] \subset \{ X \in J | \tau(X) = 0 \}
\]

for \( \tau = \text{Tr} \), \( J = F \) and any ideal \( I \supset (\omega) \). By Proposition 6.3 below (see also the remark following it), equality holds for \( \tau = \text{Tr} \), \( J = \mathcal{L}_1 \) and an ideal \( I \supset \mathcal{L}_1 \) to which \( \text{Tr} \) can be extended (i.e., \( \omega \notin \Sigma(I) \)) if and only if \( \text{se}(\omega) \subset I \). Notice that if \( \text{Tr} \) is extendable to \( I \), then \( \text{Tr} \) is extendable also to \( \text{se}(\omega) + I \) as \( \omega \notin \Sigma(\text{se}(\omega) + I) \). So every maximal ideal \( I \) for the extension must contain \( \text{se}(\omega) \) and satisfies the set equality.

(iv) Although \( \text{Tr} \) is positive on \( \mathcal{L}_1 \) and it has extensions to any ideal \( I \) properly containing \( \mathcal{L}_1 \) but not containing \( \omega \) (uncountably many according to Corollary 7.6(iii)), none of these extensions can be positive. Indeed, as is well known (e.g., see the proof of [39, Lemma 2.15] or [11, Remark 2.5]), \( \tau \geq \tau(\text{diag}(1, 0, 0, \ldots)) \text{Tr} \), for any positive trace \( \tau \). Thus if \( I \) properly contains \( \mathcal{L}_1 \), it follows that \( \tau(\text{diag}(1, 0, 0, \ldots)) = 0 \), so \( \tau \) is singular, i.e., \( \tau \) does not extend \( \text{Tr} \).

The following result will also be useful.

**Proposition 5.5.** Let \( I \) be an ideal for which \( \omega \notin \Sigma(\text{se} I) \). Then

\[
(\mathcal{L}_1 + [I, B(H)])^+ = \mathcal{L}_1^+.
\]

**Proof.** Let \( 0 \leq X \in \mathcal{L}_1 + [I, B(H)] \) and so \( X - T \in [I, B(H)] \) for some \( T \in \mathcal{L}_1 \). Since \( X = X^* \) and \( [I, B(H)] = [I, B(H)]^* \), assume without loss of generality that \( T = T^* \). Let \( f_j \) be an orthonormal basis for \( \mathcal{N}(X - T) \), the null space of \( X - T \), and let \( e_j \) be an orthonormal basis of eigenvectors of \( X - T \) for \( \mathcal{N}(X - T)^+ \) arranged so that \(|((X - T)e_j, e_j)|| \) is monotone nonincreasing. Since \( \sum_j (X f_j, f_j) = \sum_j (T f_j, f_j) < \infty \), to prove that \( X \in \mathcal{L}_1 \) it suffices to show that \( \sum_j (X e_j, e_j) < \infty \).

But if otherwise \( \sum_j^\infty (X e_j, e_j) = \infty \), then \( \sum_j^\infty ((X - T) e_j, e_j) = \infty \) since \( T \in \mathcal{L}_1 \), and so \( \omega = o\left(\frac{\sum_{j=1}^n ((X - T)e_j, e_j)}{n}\right) \). By Theorem 2.2, \( |\sum_{j=1}^n ((X - T)e_j, e_j)| \leq \xi \) for some \( \xi \in \Sigma(I) \) and hence \( \omega = o(\xi) \), against the hypothesis. \( \square \)

**Remark 5.6.**

(i) The condition \( \omega \notin \Sigma(\text{se} I) \) is also necessary since in [20] Lemma 6.2(iv) we show that if \( \omega \in \Sigma(\text{se} I) \), then \( I \supset \mathcal{L}_1 \) and therefore \( [I, B(H)]^+ = (a I)^+ \supset \mathcal{L}_1^+ \).

(ii) If \( \omega \notin \Sigma(I) \) and \( I \supset \mathcal{L}_1 \), then the extension of \( \text{Tr} \) to \( I \) is unique only in the trivial case \( I = \mathcal{L}_1 \). Indeed, from Proposition 5.3, uniqueness implies \( I \subset \mathcal{L}_1 + [I, B(H)] \), which implies \( I^+ \subset \mathcal{L}_1^+ \) by Proposition 5.3. Corollary 7.6(iii) will show that, but for the \( I = \mathcal{L}_1 \) case, there are always uncountably many linearly independent extensions of \( \text{Tr} \) to \( I \).
Trace extensions find natural applications to questions on *elementary operators*. If \( A_i, B_i \in B(H) \), then the \( B(H) \)-map

\[
B(H) \ni T \to \Delta(T) := \sum_{i=1}^{n} A_i T B_i
\]

is called an elementary operator and its adjoint \( B(H) \)-map is \( \Delta^*(T) := \sum_{i=1}^{n} A_i^* T B_i^* \). Elementary operators include commutators and intertwiners and hence their theory is connected to the structure of commutator spaces. The Fuglede-Putnam Theorem [15, 29] states that for the case \( \Delta(T) = \Delta^*(T) = 0 \). Also for \( n = 2 \), Weiss [33] generalized this further to the case where \( \{A_i\} \) and \( \{B_i\}, i = 1, 2 \), are separately commuting families of normal operators by proving that \( \Delta(T) \in \mathcal{L}_2 \) implies \( \Delta^*(T) \in \mathcal{L}_2 \) and \( \|\Delta(T)\|_2 = \|\Delta^*(T)\|_2 \). (This is also a consequence of Voiculescu’s [33] Theorem 4.2 and Introduction to Section 4) but neither Weiss’ nor Voiculescu’s methods seem to apply to the case \( n > 2 \). In [31] Shulman showed that for \( n = 6 \), \( \Delta(T) = 0 \) does not imply \( \Delta^*(T) \in \mathcal{L}_2 \).

If we impose some additional conditions involving ideals on the families \( \{A_i\}, \{B_i\} \) and \( T \), we can extend these implications to arbitrary \( n \) past the obstruction found by Shulman.

Assume that \( \{A_i\}, \{B_i\}, i = 1, \ldots, n \), are separately commuting families of normal operators and let \( T \in B(H) \).

Define the following ideals:

\[
L := (\sum_{i=1}^{n}(A_i T)(B_i))^2, \quad L_* := (\sum_{i=1}^{n}(A_i^* T)(B_i))^2, \\
R := (\sum_{i=1}^{n}(A_i)(TB_i))^2, \quad R_* := (\sum_{i=1}^{n}(A_i)(TB_i^*))^2 \text{ and} \\
I_{\Delta,T} := L \cap L_* \cap R \cap R_* \quad \text{and} \quad S = (\sum_{i=1}^{n}(A_i TB_i)) \cap L^{1/2} \cap R^{1/2}
\]

where \((X)\) denotes the principal ideal generated by the operator \( X \) and \( MN \) (resp., \( M + N \)) denotes the product (resp., sum) of the ideals \( M, N \). Then \( I_{\Delta,T} \) and \( S \) are either \( \{0\} \), \( B(H) \), or a principal ideal.

**Proposition 5.7.** If \( \omega \notin \Sigma(I_{\Delta,T}) \), then \( \Delta(T) \in \mathcal{L}_2 \) implies

\[
\Delta^*(T) \in \mathcal{L}_2 \text{ and } \|\Delta(T)\|_2 = \|\Delta^*(T)\|_2.
\]

**Proof.** Define \( I_1 = L \cap L_* \cap (R + R_*) \) and \( I_2 = R \cap R_* \cap (L + L_*) \) so \( I_{\Delta,T} = I_1 \cap I_2 \). Assume first that \( \omega \notin \Sigma(I_1) \). We start by showing that \( |\Delta^*(T)|^2 - |\Delta(T)|^2 \in [L, B(H)] \). Observe that

\[
|\Delta(T)|^2 = \sum_{i,j=1}^{n} B_j^* T^* A_j^* A_i T B_i \\
|\Delta^*(T)|^2 = \sum_{i,j=1}^{n} B_i T^* A_i A_j^* T B_j^*.
\]
Then for each $i, j,$
\[ B^*_j T^* A_j^* A_i T B_i - T^* A_j^* A_i T B_i B_j^* \in [(B^*_j), (T^* A_j^*) (A_i T) (B_i)] \]
\[ = [(B_j^*), (A_j T) (A_i T) (B_i)] \]
\[ = [(A_i T) (B_j^*) (A_i T) (B_i), B(H)] \subset [L, B(H)]. \]

Here use the elementary facts that $(X) = (X^*)$ for every operator $X$, that the product of ideals is a commutative operation, and use the deep identity $[M, N] = [M N, B(H)]$ [13, Theorem 5.10] for ideals $M, N$. By the Fuglede-Putnam Theorem [29] and the assumption that $\{B_i\}$ are normal and commuting we get that, for all $i, j$:
\[ T^* A_j^* A_i T B_i B_j^* = T^* A_j^* A_i T B_j^* B_i. \]

Then, as above,
\[ T^* A_j^* A_i T B_j^* B_i - B_j T^* A_j^* A_i T B_j^* \in [L, B(H)]. \]

Again by the Fuglede-Putnam Theorem, $B_j T^* A_j^* A_i T B_j^* = B_j T^* A_i A_j^* T B_j^*$, which proves the claim. Interchanging the role of $\Delta$ and $\Delta^*$ yields also $|\Delta^*(T)|^2 - |\Delta(T)|^2 \in [L, B(H)]$. On the other hand, by the same argument, for all $i, j$ one has
\[ B_j^* T^* A_j^* A_i T B_i - A_j^* A_i T B_i B_j^* T^* \in [R, B(H)] \]
and by applying twice the Fuglede-Putnam Theorem,
\[ A_j^* A_i T B_i B_j^* T^* = A_j A_j^* T B_j^* B_i T^*. \]

Similarly,
\[ A_i A_j^* T B_j^* B_i T^* - B_i T^* A_i A_j^* T B_j^* \in [R, B(H)] \]
and hence
\[ |\Delta^*(T)|^2 - |\Delta(T)|^2 \in [R, B(H)] + [R, B(H)] = [R + R, B(H)]. \]

A simple consequence of Theorem 2.2 is that for ideals $M, N,$
\[ [M, B(H)] \cap [N, B(H)] = [M \cap N, B(H)]. \]

Therefore $|\Delta^*(T)|^2 - |\Delta(T)|^2 \in [I_1, B(H)]$.

If $\Delta(T) \in \mathcal{L}_2$ and hence $|\Delta(T)|^2 \in \mathcal{L}_1$, then by Proposition 5.5
\[ |\Delta^*(T)|^2 \in (\mathcal{L}_1 + [I_1, B(H)])^+ = \mathcal{L}_1^+. \]

Moreover, by Proposition 5.3, there is a trace extension $\tau$ of $Tr$ from $\mathcal{L}_1$ to $\mathcal{L}_1 + I_1$. Since $\tau$ vanishes on $[I_1, B(H)] \subset \mathcal{L}_1 + [I_1, B(H)]$, so $\tau(|\Delta(T)|^2) = \tau(|\Delta^*(T)|^2)$ and hence $Tr(|\Delta(T)|^2) = Tr(|\Delta^*(T)|^2)$.

If $\omega \in \Sigma(I_1)$, then $\omega \notin \Sigma(I_2)$ and then we apply the same arguments to show that $\Delta^*(T)(\Delta^*(T))^* - \Delta(T)(\Delta(T))^* \in [I_2, B(H)]$ and to draw the same conclusions. $\square$

A sufficient condition independent of $T$ that insures that $\omega \notin \Sigma(I_{\Delta,T})$ is
\[ \omega^{1/4} \neq O(\sum_{i=1}^n (s(A_i) + s(B_i))). \]
So also is the condition $\omega^{1/2} \neq O(\sum_{i=1}^n s(A_i))$ or the condition $\omega^{1/2} \neq O(\sum_{i=1}^n s(B_i))$. 
Propositions 5.3 and 5.5 can also be applied to a problem of Shulman. Let
\[ \Delta(T) = \sum_{i=1}^{n} A_i T B_i \]
be an elementary operator where the operators \( A_i \) and \( B_i \) are not assumed to be commuting or normal. Shulman showed that the composition \( \Delta^*(\Delta(T)) = 0 \) does not imply \( \Delta(T) = 0 \) and conjectured that this implication holds under the additional assumption that \( \Delta(T) \in \mathcal{L}_1 \). In the case that the ideal \( S \) is “not too large” we can prove the implication without making this assumption.

**Proposition 5.8.** If \( \omega \notin \Sigma(S) \), then \( \Delta^*(\Delta(T)) \in \mathcal{L}_1 \) implies that \( \Delta(T) \in \mathcal{L}_2 \) and \( \|\Delta(T)\|_2 = Tr T^* \Delta^*(\Delta(T)) \).

In particular, if \( \Delta^*(\Delta(T)) = 0 \) then \( \Delta(T) = 0 \).

**Proof.** Let \( S_L = (\sum_{i=1}^{n}(A_i T B_i)) \cap L^{1/2} \) and \( S_R = (\sum_{i=1}^{n}(A_i T B_i)) \cap R^{1/2} \), so that \( S = S_L \cap S_R \). Assume that \( \omega \notin \Sigma(S_L) \). Using the first step in the proof of Proposition 5.7 one has
\[ |\Delta(T)|^2 - T^* \Delta^*(\Delta(T)) = \sum_{i,j=1}^{n} (B_j^* T^* A_j^* A_i T B_i - T^* A_j^* A_i T B_i B_j^*) \in [S_L, B(H)]. \]

So if \( \Delta^*(\Delta(T)) \in \mathcal{L}_1 \) then \( |\Delta(T)|^2 \in (\mathcal{L}_1 + [S_L, B(H)])^+ = \mathcal{L}_1^+ \) by Proposition 5.5.

The required equality then follows by the same reasoning as in the conclusion of the proof of Proposition 5.7.

If \( \omega \in \Sigma(S_L) \), then \( \omega \notin \Sigma(S_R) \) and we reach the same conclusions by considering \( |\Delta(T)^2 - \Delta^*(\Delta(T)) T^* | \in [S_R, B(H)] \).

6. **Uniqueness of Traces**

An ideal \( I \) supports a unique nonzero trace (up to scalar multiplication) precisely when \( \dim \left( \frac{I}{I \cap B(H)} \right) = 1 \). In this section we characterize in terms of arithmetic means at infinity when this occurs for those ideals where \( \omega \notin \Sigma(I) \).

The next proposition is based on Theorem 2.2 which Kalton [27] extended to non-normal operators for the class of geometrically stable ideals. These are the ideals \( I \) for which \( \Sigma(I) \) is invariant under geometric means, that is,

\[ \xi \in \Sigma(I) \text{ implies } \xi_g := <(\xi_1 \cdots \xi_n)^{1/n} > \in \Sigma(I). \]

Notice that if \( X \in I \) and \( \lambda(X) \) and \( \tilde{\lambda}(X) \) are two different orderings of the sequence of all the eigenvalues (if any) of \( X \), repeated according to algebraic multiplicity, augmented by adding infinitely many zeros when there are only a finite number of nonzero eigenvalues, and arranged so that both \( |\lambda(X)| \) and \( |\tilde{\lambda}(X)| \) are monotone nonincreasing, then \( |\lambda(X)| \) and \( |\tilde{\lambda}(X)| \in \Sigma(I) \) and it is elementary to show that \( |\tilde{\lambda}(X)| = 2|\lambda(X)| \). Similarly, \( |\lambda(X)_{a\infty}| \leq |\lambda(X)|_{a\infty} | + 2|\lambda(X)| \) when \( X \in \mathcal{L}_1 \cap I \). For this, notice that there is an increasing sequence of indices \( n_k \) with \( n_1 = 1 \) for which \( |\lambda(X)|_{j} = |\lambda(X)|_{j} = |\lambda(X)|_{n_k} \) for \( n_k \leq j < n_{k+1} \). Then
\[ \sum_{n_k}^{n_{k+1}} \lambda(X)_j = \sum_{n_k}^{n_{k+1}} \tilde{\lambda}(X)_j \] for all \( k \) and hence \( \sum_{n_k}^{\infty} \lambda(X)_j = \sum_{n_k}^{\infty} \tilde{\lambda}(X)_j \). If \( n_k \leq n < n_{k+1} \) then

\[
\begin{align*}
| (\tilde{\lambda}(X)_{a\infty})_n | - | (\lambda(X)_{a\infty})_n | & \leq | (\tilde{\lambda}(X)_{a\infty})_n - (\lambda(X)_{a\infty})_n | \\
& = \frac{1}{n} \left( \sum_{n+1}^{\infty} \tilde{\lambda}(X)_j - \sum_{n+1}^{\infty} \lambda(X)_j \right) \\
& = \frac{1}{n} \left( \sum_{n_k}^{n} \tilde{\lambda}(X)_j - \sum_{n_k}^{n} \lambda(X)_j \right) \\
& \leq 2 | \lambda(X)_n | .
\end{align*}
\]

Thus \( \lambda(X)_a \in S(I) \) (resp., \( \lambda(X)_{a\infty} \in S(I) \)) if and only if \( \tilde{\lambda}(X)_a \in S(I) \) (resp., \( \tilde{\lambda}(X)_{a\infty} \in S(I) \)). This illustrates in an elementary way why the choice of the ordering for \( \lambda(X) \) does not matter in Theorem 2.2 and in Proposition 6.1 below. (See also [13, Theorem 5.6].)

**Proposition 6.1.** Let \( I \) be an ideal, let \( X \in \mathcal{L}_1 \cap I \), and assume that either \( X \) is normal or \( I \) is geometrically stable. Then

\[ X \in F + [I, B(H)] \] if and only if \( \lambda(X)_{a\infty} \in S(I) \).

*Proof.* Assume first \( \omega \in \Sigma(I) \) and so, by Theorem 2.2, \( F \subset [I, B(H)] \). Because
\[ \lambda(X)_a + \lambda(X)_{a\infty} = (Tr X) \omega , \] one sees that \( \lambda(X)_{a\infty} \in S(I) \) if and only if \( \lambda(X)_a \in S(I) \), which, by Theorem 2.2 if \( X \) is normal or by [27] if \( I \) is geometrically stable, is then equivalent to the condition \( X \in [I, B(H)] = F + [I, B(H)] \).

Assume now that \( \omega \notin \Sigma(I) \). In case \( X \) is quasinilpotent, i.e., \( \lambda(X) = 0 \), then \( \lambda(X)_{a\infty} = \lambda(X)_a = 0 \) are in \( S(I) \) and so, by Theorem 2.2 if \( X \) is normal or, by [27], if \( I \) is geometrically stable, one has that \( X \in [I, B(H)] \). On the other hand, if \( \lambda(X) \neq 0 \), let \( P \) be a rank one projection on an eigenvector of \( X \) corresponding to the eigenvalue \( \lambda(X)_1 \). From the proof of Lemma 5.2 ii) and by Lemma 5.2 i), \( X \in F + [I, B(H)] \) if and only if \( Y := X - (Tr X)P \in [I, B(H)] \). Now, by Theorem 2.2 if \( X \) and hence \( Y \) are normal or, by [27], if \( I \) is geometrically stable, \( Y \in [I, B(H)] \) if and only if \( \lambda(Y)_a \in S(I) \). \( X \) can be represented as a \( 2 \times 2 \) block matrix where the upper left block is upper triangular (and \( \lambda(X)_1 \) lies in its \((1,1)\) position) and the lower right block is quasinilpotent [12, Proposition 2.1]. Also it is known that for compact upper triangular operators, the diagonal sequence is precisely the eigenvalue sequence repeated by algebraic multiplicity. Therefore an eigenvalue sequence of \( Y \) counting multiplicity is

\[ < \lambda(X)_1 - Tr X, \lambda(X)_2, \lambda(X)_3, \cdots > . \]

Thus a monotonization in modulus of this sequence is given by

\[
\lambda(Y) = \begin{cases} 
< \lambda(X)_2, \lambda(X)_3, \ldots, \lambda(X)_p, \lambda(X)_1 - Tr X, \lambda(X)_{p+1}, \cdots > \\
\text{for some } p \geq 1 \text{ if } \lambda(X)_1 \neq Tr X \\
< \lambda(X)_2, \lambda(X)_3, \cdots > \text{ if } \lambda(X)_1 = Tr X
\end{cases}
\]
where for $p = 1$ we mean $\lambda(Y) = < \lambda(X)_1 - Tr X, \lambda(X)_2, \lambda(X)_3, \cdots >$. Then

$$
\sum_{j=1}^{n} \lambda(Y)_j = \begin{cases}
\sum_{j=1}^{n} \lambda(X)_j - Tr X = -\sum_{j=n+1}^{\infty} \lambda(X)_j & \text{if } \lambda(X)_1 \neq Tr X \\
\sum_{j=1}^{n} \lambda(Y)_j = -\sum_{j=n+2}^{\infty} \lambda(X)_j & \text{if } \lambda(X)_1 = Tr X
\end{cases}
$$

for $n \geq p$

for $n = 1, 2, \ldots$

So, in either case, $\lambda(Y)_a \in S(I)$ if and only if $\lambda(X)_{a^\infty} \in S(I)$. \hfill \Box

**Corollary 6.2.** Let $I \neq \{0\}$ be an ideal.

(i) If $\omega \notin \Sigma(I)$, then $(F + [I, B(H)])^+ = (a^\infty I)^+$.

(ii) If $\omega \in \Sigma(I)$, then $(F + [I, B(H)])^+ = (a I)^+$.

(iii) $(F + [I, B(H)])^+$ is hereditary (i.e., solid).

**Proof.**

(i) By Proposition 5.5 (ii) $(F + [I, B(H)])^+ \subset L_1^+$ and so by Proposition 6.1

$$X \in (F + [I, B(H)])^+ \text{ if and only if } X \in (L_1 \cap I)^+ \text{ and } \lambda(X)_{a^\infty} \in \Sigma(I),$$

i.e., $X \in (a^\infty I)^+$.

(ii) That $\omega \in \Sigma(I)$ implies $F \subset [I, B(H)]$ and $[I, B(H)]^+ = (a I)^+$ both follow from Theorem 2.2 (see also its succeeding reformulation for positive operators).

(iii) This is immediate from (i) and (ii) since the positive cone of an ideal is hereditary. \hfill \Box

So, for instance, by combining (i) with the proof of Proposition 4.18(ii) one obtains $(F + [L_1, B(H)])^+ = (a^\infty (L_1))^+ = L(\sigma (log))^+$ (the positive cone of a Lorentz ideal).

**Remark 6.3.**

(a) In [13], Theorem 5.11(i) it is shown that $|X| \in [I, B(H)]$ if and only if $(X) \subset [I, B(H)]$. The proof depends on $[I, B(H)]^+ = (a I)^+$ being hereditary. By the same argument combined with Corollary 6.2(iii), it follows that

$$|X| \in F + [I, B(H)] \text{ if and only if } (X) \subset F + [I, B(H)].$$

(b) $X \in [I, B(H)]$ implies $|X| \in [I, B(H)]$ (resp., if $\omega \notin \Sigma(I)$, $X \in F + [I, B(H)]$ implies $|X| \in F + [I, B(H)]$) if and only if $I$ is am-stable (resp., $I$ is am-$\infty$ stable). The condition is sufficient: if $I$ is am-stable (resp., am-$\infty$ stable), then $[I, B(H)] = I$ (resp., $F + [I, B(H)] = I$) is an ideal and for ideals, containment of $X$ and $|X|$ are equivalent. The condition is necessary: for every $Y \in I$ and in particular for every $Y \in I^+$,

$$Y \oplus (-Y) = \begin{pmatrix} 0 & Y \\ 0 & 0 \end{pmatrix} \begin{pmatrix} 0 & 0 \\ I & 0 \end{pmatrix} - \begin{pmatrix} 0 & 0 \\ I & 0 \end{pmatrix} \begin{pmatrix} 0 & Y \\ 0 & 0 \end{pmatrix} \in [I, B(H)]$$

where $H$ is identified with $H \oplus H$ and $I$ is identified with $M_2(I)$, the set of $2 \times 2$ matrices with entries in $I$. Thus by assumption $|Y \oplus (-Y)| = Y \oplus Y \in [I, B(H)]$, and $Y \oplus 0 \in [I, B(H)]$ for every $Y \in I^+$ by hereditariness. Since every positive $X \in I$ is unitarily equivalent to $Y \oplus 0 + 0 \oplus Z$ for some $Y, Z \in I^+$, it follows that $I^+ \subset [I, B(H)]^+ = (a I)^+$. Thus $I = I_a$, i.e., $I$ is am-stable. The same argument
shows that when $\omega \notin \Sigma(I)$, if $X \in F + [I, B(H)]$ implies $|X| \in F + [I, B(H)]$, then $I^+ \subseteq (F + [I, B(H)])^+ = (a_\infty I)^+$ by Corollary 6.2(i) and hence $I$ is am-$\infty$ stable.

(c) Notice that the same $2 \times 2$ matrix argument shows that $I$ is the smallest ideal containing $[I, B(H)]$.

**Proposition 6.4.** For ideals $I$ and $J \neq \{0\}$ and arbitrary $J$, if $\omega \notin \Sigma(I)$, then the following are equivalent.

(i) $\dim \frac{J + [I, B(H)]}{[I, B(H)]} = 1$

(ii) $J \subseteq F + [I, B(H)]$

(iii) $J \subseteq L_1$ and $J \cap [I, B(H)] = \{X \in J \mid Tr X = 0\}$

(iv) $J \subseteq a_\infty I$

(iv') $J \subseteq L_1$ and $J_{a_\infty} \subseteq I$

*Proof.*

(i) $\iff$ (ii) Immediate from Lemma 5.2(ii) and the identity:

$$\dim \frac{J + [I, B(H)]}{[I, B(H)]} = \dim \frac{J + [I, B(H)]}{F + [I, B(H)]} + \dim \frac{F + [I, B(H)]}{[I, B(H)]}.

(ii) $\iff$ (iv) This follows from the equivalences $J \subseteq F + [I, B(H)]$ if and only if $J^+ \subseteq (F + [I, B(H)])^+ = (a_\infty I)^+$ by Corollary 6.2(i), if and only if $J \subseteq a_\infty I$.

(iv) $\iff$ (iv') See Corollary 4.8(iii).

(ii) $\Rightarrow$ (iii) $J \subseteq L_1$ since (ii) implies (iv'), hence

$$J \cap [I, B(H)] \subseteq \{X \in J \mid Tr X = 0\}$$

follows from Lemma 5.2(i) without needing to invoke hypothesis (ii). For the reverse inclusion, let $X \in J$ and $Tr X = 0$. By (ii), $X - T \in [I, B(H)]$ for some $T \in F$, hence $Tr(X - T) = 0$ by the previous inclusion, and therefore $Tr T = 0$. Then $T \in [F, B(H)] \subseteq [I, B(H)]$ as seen in the proof of Lemma 5.2(ii), hence $X \in [I, B(H)]$

and thus (iii) holds.

(iii) $\Rightarrow$ (ii) Let $X \in J$ and let $P$ be a rank one projection. But then $Tr(X - (Tr X)P) = 0$, hence $X - (Tr X)P \in [I, B(H)]$, and thus $X \in F + [I, B(H)]$.

The equivalence of (iii) and (iv') also follows from [13, Theorem 5.11(iii)].

A special case is when $I = J$ is a principal ideal, and then Proposition 6.4 subsumes [13, Corollary 5.19]. Another special case is when $J = L_1$, i.e.,

$$L_1 \cap [I, B(H)] = \{X \in L_1 \mid Tr X = 0\}$$

if and only if $L_1 = a_\infty I$ (since $a_\infty I \subseteq L_1$),

which by Corollary 4.9(i) is equivalent to the condition $se(\omega) \subseteq I$.

The analog below of Proposition 6.4 for the case when $\omega \in \Sigma(I)$ is simpler and its proof is left to the reader. The equivalence of (iii) and (iii') is a simple consequence of the five chain of inclusions presented in Section 2.
Proposition 6.5. For ideals $I$ and $J$, if $\omega \in \Sigma(I)$, then the following conditions are equivalent.

(i) $\dim \frac{I + [I, B(H)]}{[I, B(H)]} = 0$
(ii) $J \subset [I, B(H)]$
(iii) $J \subset \alpha I$
(iii') $J_\alpha \subset I$

Proposition 6.1 and Corollary 6.2 allow us to characterize the ideals with $\omega / \notin \Sigma(I)$ that support a unique trace up to scalar multiples.

Theorem 6.6. If $I \neq \{0\}$ is an ideal where $\omega / \notin \Sigma(I)$, then the following are equivalent.

(i) $I$ supports a nonzero trace unique up to scalar multiples.
(ii) $I \subset \mathcal{L}_1$ and every trace on $I$ is a scalar multiple of $\text{Tr}$.
(iii) $\dim \frac{I}{[I, B(H)]} = 1$
(iv) $I = F + [I, B(H)]$
(v) $I \subset \mathcal{L}_1$ and $[I, B(H)] = \{X \in I \mid \text{Tr } X = 0\}$
(vi) $I$ is am-$\infty$ stable, i.e., $I = \alpha I$.

Proof. The equivalence of (iii)-(vi) is the case $J = I$ in Proposition 6.4. The equivalence of (i) and (iv) follows from the case $J = F$ and $\tau = \text{Tr}$ in Proposition 5.3 which provides both the existence of a nonsingular trace on $I$ and the condition for its uniqueness. Since $\alpha I \subset \mathcal{L}_1$, (i) and (vi) imply (ii) and (ii) trivially implies (i). □

Remark 6.7. By the remarks following Definition 4.16, $\text{sta}_\infty(\mathcal{L}_1)$ is the largest am-$\infty$ stable ideal, so by Theorem 6.6, it is the largest ideal not containing $(\omega)$ that has a nonzero trace unique up to scalar multiples. We do not know whether or not an ideal $I$ containing $(\omega)$ can have a nonzero trace unique up to scalar multiples. However, nonuniqueness for large classes of ideals containing $(\omega)$ follows from Theorems 7.1, 7.2, Corollary 7.5, and Theorem 7.8.

As mentioned in the introduction, a principal ideal $(\xi)$ supports no nonzero trace precisely when $\xi$ is regular. A similar characterization of the principal ideals supporting a unique nonzero trace in terms of regularity at infinity was obtained in [39, Corollary 5.6]. It is also an immediate consequence of Theorem 6.6.

Corollary 6.8. Let $\xi \in c_0^*$ and $\omega \notin \Sigma((\xi))$. Then $(\xi)$ supports a nonzero trace unique up to scalar multiples if and only if $\xi$ is $\infty$-regular.

As remarked after Definition 4.11 a sequence $\xi \in (\ell^1)^*$ is $\infty$-regular precisely when $(\xi) = (\xi_\infty)$ or, equivalently, $\xi_\infty = O(\xi)$ (see Theorem 4.12). Moreover, by Remark 6.7 such a sequence must be contained in $\Sigma(\text{sta}_\infty(\mathcal{L}_1))$ and hence $\sum_{n=1}^\infty \xi_n \log^m n < \infty$ for every $m$ (see remarks succeeding Proposition 4.18).
7. Infinite Codimension

In this section we present some conditions under which \([I, B(H)]\) has infinite codimension in \(I\). First notice that by setting \(I = J\) in the identity in the proof of (i) \(\Leftrightarrow\) (ii) in Proposition 6.1 \([I, B(H)]\) has minimal codimension in \(I\) precisely when \(I = F + [I, B(H)]\).

Thus if \(\omega \in \Sigma(I)\), the codimension is zero precisely when \(I\) is am-stable (Theorem 2.2), and if \(\omega \notin \Sigma(I)\), the codimension is one precisely when \(I\) is am-\(\infty\) stable (Theorem 6.6). We conjecture that in all other cases, i.e., whenever \(I \neq F + [I, B(H)]\), the codimension of \([I, B(H)]\) in \(I\) is infinite, i.e., that

\[
\dim \frac{I}{[I, B(H)]} \in \begin{cases} 
1, \infty & \text{when } \omega \notin \Sigma(I) \\
0, \infty & \text{when } \omega \in \Sigma(I).
\end{cases}
\]

In order to verify this conjecture for various classes of ideals, we depend on the following result.

Theorem 7.1. If \(I\) and \(J\) are ideals and \(seJ \not\subset F + [I, B(H)]\) then \(\frac{J + [I, B(H)]}{F + [I, B(H)]}\) has uncountable dimension.

In particular, if \(seI \not\subset F + [I, B(H)]\) then \(\frac{I}{[I, B(H)]}\) has uncountable dimension.

Proof. Since \(seJ = \text{span}(seJ)^+\) and \(F + [I, B(H)]\) is a linear space, it follows that \((seJ)^+ \not\subset F + [I, B(H)]\). Thus, let \(X \in (seJ)^+ \setminus (F + [I, B(H)])\) and let \(\eta = s(X)\) be the sequence of \(s\)-numbers of \(X\). Since \(X - UXU^* \in [I, B(H)]\) for every unitary \(U\), \(\text{diag } \eta \in (seJ)^+ \setminus (F + [I, B(H)])\). By definition, \(\eta = o(\xi)\) for some \(\xi \in \Sigma(J)\) and without loss of generality assume that \(\eta \leq \xi\). Also, \(\eta_n > 0\) for all \(n\) since \(\text{diag } \eta \notin F\). Define \(\zeta(t) := \xi^t\eta^{1-t}\) for \(t \in [0,1]\). Then since \(\zeta(t) \in c_0^\ast\) and \(\zeta(\xi) \leq \xi\), also \(\zeta(t) \in \Sigma(J)\). We claim that for any choice of \(0 = t_0 < t_1 < \cdots < t_N = 1\) the cosets \(\{\text{diag } \zeta(t_j) + F + [I, B(H)]\}_{j=0}^N\) are linearly independent in \(\frac{J + [I, B(H)]}{F + [I, B(H)]}\).

Indeed, assuming otherwise, \(\text{diag } (\zeta(t_j) + \sum_{i=0}^{j-1} \lambda_i \zeta(t_i)) \in F + [I, B(H)]\) for some \(0 < j \leq N\) and some constants \(\lambda_i, i = 0, 1, \ldots, j - 1\). Since \(F + [I, B(H)]\) is a selfadjoint linear space and \(\zeta(t_i)\) are real-valued sequences, one can choose all \(\lambda_i\) to be real. Define \(\rho = \zeta(t_j) + \sum_{i=0}^{j-1} \lambda_i \zeta(t_i)\) and set \(\chi = \max(\rho, \eta)\). Since \(\zeta(t_i) = o(\zeta(t_j))\) for \(i = 0, 1, \ldots, j - 1\) and \(\eta = o(\zeta(t_j))\), one has \(\eta = o(\rho)\), so that \(\chi_n = \rho_n\) for \(n\) large enough. Thus \(\text{diag } (\rho - \chi) \in F\) and hence \(\text{diag } \chi \in F\). Since \(\chi \geq \eta\) and since \((F + [I, B(H)])^+\) is hereditary by Corollary 6.2(iii), it follows that \(\text{diag } \eta \in F + [I, B(H)]\), against the hypothesis. Thus the cosets \(\{\text{diag } \zeta(t_j) + F + [I, B(H)]\}_{j=0}^N\) are linearly independent and so \(\frac{J + [I, B(H)]}{F + [I, B(H)]}\) has uncountable dimension. This implies of course that in case \(I = J\), \(\frac{J + [I, B(H)]}{[I, B(H)]}\) also has uncountable dimension. \(\square\)

Notice that the condition \(seJ \not\subset F + [I, B(H)]\) is equivalent to

\[
seJ \not\subset \begin{cases} 
as I & \text{if } \omega \notin \Sigma(I) \\
a I & \text{if } \omega \in \Sigma(I).
\end{cases}
\]

Notice also that if \(L \subset J\) is any ideal for which \((L + [I, B(H)])^+\) is hereditary, Theorem 7.1 with the same proof remains valid if we substitute \(L + [I, B(H)]\) for \(F + [I, B(H)]\).
In the following theorem, conditions (i) and (ii) are expressed in terms of the am-stability (resp., am-∞ stability) of seI. Recall from Propositions 3.4 and 4.20 that this is equivalent to the am-stability (resp., am-∞ stability) of seI. Recall also that \( st^a(\mathcal{L}_1) \) is the smallest am-stable ideal and that \( st_{a_\infty}(\mathcal{L}_1) \) is the largest am-∞ stable ideal (Definition 4.16 and succeeding remarks).

**Theorem 7.2.** Let \( I \neq \{0\} \) be an ideal. Then \( \frac{I}{[I, B(H)]} \) has uncountable dimension if any of the following conditions hold.

(i) \( I \subset st_{a_\infty}(\mathcal{L}_1) \) and seI is not am-∞ stable.

(ii) \( I \supset st^a(\mathcal{L}_1) \) and seI is not am-stable.

(iii) \( I \not\subset st_{a_\infty}(\mathcal{L}_1) \) and \( I \not\supset st^a(\mathcal{L}_1) \).

**Proof.**

(i) Since \( \omega \notin \Sigma(I) \) because \( st_{a_\infty}(\mathcal{L}_1) \subset \mathcal{L}_1 \) by Proposition 4.20 seI \( \not\subset F + [I, B(H)] \) and the conclusion follows from Theorem 7.1.

(ii) \( F \subset [I, B(H)] \) since \( \omega \in \Sigma(I) \), and thus seI \( \not\subset F + [I, B(H)] \), by Proposition 3.4 and the conclusion follows from Theorem 7.1.

(iii) Assume first that \( \omega \notin \Sigma(I) \). As \( I \not\subset st_{a_\infty}(\mathcal{L}_1) \), one has seI \( \not\subset st_{a_\infty}(\mathcal{L}_1) \). Since \( st_{a_\infty}(\mathcal{L}_1) \) is the largest am-∞ ideal, seI is not am-∞ stable, hence by Proposition 4.20 seI \( \not\subset a_\infty I \), and so by Corollary 6.2(i), seI \( \not\subset F + [I, B(H)] \).

Assume now that \( \omega \in \Sigma(I) \). Since \( I \not\supset st^a(\mathcal{L}_1) \), one has seI \( \not\supset st^a(\mathcal{L}_1) \). As \( st^a(\mathcal{L}_1) \) is the smallest am-stable ideal, seI is not am-stable, hence by Proposition 3.4 seI \( \not\subset [I, B(H)] = F + [I, B(H)] \).

In either case the result follows now from Theorem 7.1.

Theorem 7.2(ii),(iii) were motivated by an analysis of ideals of the form \( I = se(\xi_a) + (\xi) \) when \( \xi \) is irregular and nonsummable.

We can extend the method of Theorem 7.2 in two directions.

**Corollary 7.3.** Let \( I \neq \{0\} \) be an ideal. Then \( \frac{I}{[I, B(H)]} \) has uncountable dimension if any of the following conditions hold.

(i) \( I \not\supset st^a(\mathcal{L}_1) \) and \( I \subset J \) but \( I \not\subset st_{a_\infty}(J) \) for some soft-complemented ideal J.

(ii) \( I \not\subset st_{a_\infty}(\mathcal{L}_1) \) and \( J \subset I \) but \( st^a(J) \not\subset I \) for some soft-edged ideal J.

**Proof.**

(i) By Theorem 7.2(iii) it remains to consider the case that \( I \subset st_{a_\infty}(\mathcal{L}_1) \). Since \( I \not\subset st_{a_\infty}(J) \), then for some \( n \geq 0 \), \( I \subset a_n J \) but \( I \not\subset a_{n+1} J \). And since \( a_n J \) is soft-complemented as well by Lemma 4.19(i), assume without loss of generality that \( n = 0 \), i.e., \( I \not\subset a_0 J \). But then seI \( \not\subset a_0 J \), while seI \( \subset J \), hence \( a_\infty(seI) \subset a_\infty J \), so seI is not am-∞ stable. Hence the conclusion follows from Theorem 7.2(ii) and Proposition 4.20.

(ii) By Theorem 7.2(iii) it remains to consider the case that \( I \supset st^a(\mathcal{L}_1) \) and that for some \( n \geq 0 \), \( J_a n \subset I \) but \( J_{a^{n+1}} \not\subset I \). In particular, this implies that \( J_{a^n} \not\subset \mathcal{L}_1 \) since otherwise \( st^a(J) \supset st^a(\mathcal{L}_1) \subset I \) against the hypothesis. Hence, since \( J \) is soft-edged, \( J_{a^n} \) is soft-edged by Lemma 3.3(ii). Thus \( J_{a^n} \subset seI \), and hence \( J_{a^{n+1}} \subset (seI)_a \) while \( J_{a^{n+1}} \not\subset seI \). This shows that seI is not am-stable and hence the conclusion follows from Theorem 7.2(ii).
Using a method similar to the one employed in Theorem 7.2 and building on Propositions 6.4 and 6.5, we obtain:

**Proposition 7.4.** If \( I \) and \( J \) are nonzero ideals and if \( I \) is soft complemented or \( J \) is soft-edged, then

\[
\dim \frac{J + [I, B(H)]}{[I, B(H)]} = \begin{cases} 
1 \text{ or uncountable} & \text{if } \omega \notin \Sigma(I) \\
0 \text{ or uncountable} & \text{if } \omega \in \Sigma(I). 
\end{cases}
\]

**Proof.** Assume that \( \omega \notin \Sigma(I) \). If \( \dim \frac{J + [I, B(H)]}{[I, B(H)]} \neq 1 \), then by Proposition 6.4, \( J \not\subset a_\infty I \). If \( J \) is soft-edged, then \( seJ \not\subset a_\infty I \). If \( I \) is soft-complemented, then \( seJ \subset a_\infty I \) would imply that \( J \subset scJ = sc(se(J)) \subset sc(a_\infty I) = a_\infty (scI) = a_\infty I \) (see Lemma 4.19(i)). Thus, in either case, \( seJ \not\subset a_\infty I \), which is equivalent to \( seJ \not\subset F + [I, B(H)] \) by Proposition 6.4. Uncountable dimension then follows from Theorem 7.1.

The case when \( \omega \in \Sigma(I) \) (i.e., \( F \subset [I, B(H)] \)) follows similarly from Proposition 6.5 and Lemma 3.3(i). \[\square\]

A case of special interest is when \( I = J \) which, for soft-edged and soft-complemented ideals, proves the codimension conjecture stated in the introduction.

**Corollary 7.5.** If \( I \) is a soft-edged or soft-complemented ideal, then

\[
\dim \frac{I}{[I, B(H)]} = \begin{cases} 
1 \text{ or uncountable} & \text{if } \omega \notin \Sigma(I) \\
0 \text{ or uncountable} & \text{if } \omega \in \Sigma(I). 
\end{cases}
\]

In particular, \( \dim \frac{I}{[I, B(H)]} \) is uncountable since \( \omega \) is not regular.

Another case of interest is when \( I \) or \( J \) are the trace class \( L_1 \), which is both soft-edged and soft-complemented.

**Corollary 7.6.** Let \( I \) be a nonzero ideal. Then

(i)

\[
\dim \frac{I + [L_1, B(H)]}{[L_1, B(H)]} = \begin{cases} 
1 & \text{if } I \subset a_\infty(L_1) \\
\text{uncountable} & \text{if } I \not\subset a_\infty(L_1) 
\end{cases}
\]

(ii)

\[
\dim \frac{L_1 + [I, B(H)]}{[I, B(H)]} = \begin{cases} 
0 & \text{if } \omega \in \Sigma(I) \\
1 & \text{if } \omega \in \Sigma(scI) \setminus \Sigma(I) \\
\text{uncountable} & \text{if } \omega \notin \Sigma(scI) 
\end{cases}
\]

(iii) If \( \omega \notin \Sigma(I) \) then

\[
\dim \frac{I}{I \cap L_1 + [I, B(H)]} = \begin{cases} 
0 & \text{if } I \subset L_1 \\
\text{uncountable} & \text{if } I \not\subset L_1 
\end{cases}
\]

In particular, if \( L_1 \not\subset I \), then there are uncountably many linearly independent extensions of \( \text{Tr} \) from \( L_1 \) to \( I \).
Proof.
(i) Immediate from Propositions 7.4 and 6.4 (the equivalence of (i) and (iv)) since \( \omega \notin \Sigma(L_1) \).
(ii) Recall that \( L_1 \subset [I, B(H)] \) if and only if \( \omega \in \Sigma(I) \). If \( \omega \notin \Sigma(I) \), by Proposition 6.4, \( \dim \frac{\xi_1 + [I, B(H)]}{[I, B(H)]} = 1 \) when \( L_1 \subset a_\infty I \), which by Corollary 4.9(i) is equivalent to \( \omega \in \Sigma(scI) \), and \( \dim \frac{\xi_1 + [I, B(H)]}{[I, B(H)]} \) is uncountable otherwise.
(iii) First notice that if \( seI \subset I \cap L_1 + [I, B(H)] \), then
\[
(seI)^+ \subset (I \cap L_1 + [I, B(H)])^+ = (I \cap L_1)^+ \subset L_1^+
\]
and hence \( seI \subset L_1 \), where the equality follows from Proposition 5.5. Since \( L_1 \) is soft-complemented, \( I \subset scI = sc(seI) \subset L_1 \). Thus, if \( I \not\subset L_1 \), \( seI \not\subset I \cap L_1 + [I, B(H)] \).

By the second remark following Theorem 7.1, \( \dim \frac{I \cap L_1 + [I, B(H)]}{I} \) is uncountable. The particular case is then clear. \( \square \)

Remark 7.7. Dixmier proved in [11] that the am-closure \( (\eta)^- = \alpha(\eta_a) \) of a principal ideal \( (\eta) \) for which \( (\eta) \subset se(\eta)_a \) (i.e., \( \eta = o(\eta_a) \), which is equivalent to \( \frac{(\eta_a)_n}{(\eta)_n} \to \frac{1}{2} \)) supports a positive singular trace. In [13] Section 5.27 Remark 1 it was noted that Dixmier’s construction can be used to show that \( \dim \frac{\eta^-}{cl(\eta)^-, B(H)} = \infty \) where \( cl \) denotes the closure in the principal ideal norm. Corollary 7.3 shows that \( \dim \frac{\eta^-}{(\eta)^-, B(H)} \) is uncountable if \( \eta \) is not am-stable precisely when \( (\eta)^- \) is not am-stable, i.e., \( \dim \frac{\eta^-}{(\eta)^-, B(H)} > 0 \). In [20] we show that \( (\eta)^- \) is always soft-complemented and so by Corollary 7.3, \( \dim \frac{\eta^-}{(\eta)^-, B(H)} \) is uncountable.

The condition in Theorem 7.2(ii) for \( [I, B(H)] \) to have infinite codimension in \( I \), namely that \( seI \) be not am-stable, is only sufficient. The next theorem presents a class of ideals \( I \) with \( seI \) am-stable but \( \dim \frac{I}{[I, B(H)]} = \infty \). The technique used does not depend on Theorem 7.1 nor on the method of its proof but is more combinatoric in nature. As indicated in Corollary 7.9 this technique can be used to prove infinite codimension for a wider class of ideals.

Theorem 7.8. For every am-stable principal ideal \( J \neq \{0\} \) there is an ideal \( I \) with \( seJ \subset I \subset J \) for which \( \dim \frac{I}{[I, B(H)]} = \infty \), yet \( seI \) and hence \( scI \) are am-stable.

Proof. Choose a generator \( \mu \) for \( \Sigma(J) \). Then \( \mu \) is regular, i.e., \( \mu \asymp \mu_a \), and hence nonsumnable. Now construct a sequence \( \xi \in c_0^* \) together with a strictly increasing sequence of indices \( p_i > i \in \mathbb{N} \) for which: (i) \( \xi \leq \mu \), (ii) \( \xi_{p_i} = \frac{1}{i} \mu_{p_i} \) and (iii) \( (\xi_a)_{p_i} \geq \frac{1}{2}(\mu_a)_{p_i} \). Set \( p_1 = 1 \), \( \xi_1 = \mu_1 \) and assume that \( p_1 < \cdots < p_i \) for \( 1 \leq i \leq p_i \) and \( \xi_i \) for \( 1 \leq i \leq p_i \) have been chosen so that (i)-(iii) hold. Define \( \xi_i := \min \{ \xi_{p_i}, \mu_i \} \) for \( p_i < i \leq p_{i+1}-1 \) where \( p_{i+1} > p_i \) and \( p_{i+1} \geq 3 \) is chosen large enough so that \( \sum_{i=1}^{p_{i+1}-1} \xi_i \geq \frac{3}{4} \sum_{i=1}^{p_{i+1}-1} \mu_i \), which is possible due to the nonsummability of \( \mu \). Define \( \xi_{p_{i+1}} := \frac{1}{i+1} \mu_{p_{i+1}} \). Then
\[
\sum_{i=1}^{p_{i+1}} \xi_i \geq \frac{3}{4} \sum_{i=1}^{p_{i+1}-1} \mu_i \geq \frac{1}{2} \sum_{i=1}^{p_{i+1}} \mu_i,
\]
the inequality following from \( \sum_{i=1}^{n+1} \mu_i \geq 2\mu_{p+1} \). Therefore (i)-(iii) hold. Notice that (ii),(iii) imply \( \xi \neq \xi_a \), i.e., \( \xi \) is irregular.

Define now \( I := seJ + (\xi) \). Since \( \xi \leq \mu \), one has \( (\xi) \subset (\mu) = J \) and hence \( seJ \subset I \subset J \). Since \( J = scJ \) because principal ideals are soft-complemented \(^{[20]}\), \( seJ \) and \( J \) form a soft pair and hence \( seI = J \) and \( seI = seJ \). Since \( J \) is am-stable, so are \( seI \) and \( scI \) (see Remark \( \text{(3.5)} \)).

Notice that \( \mu \notin \ell^1 \) implies \( \omega = o(\mu_a) \) and hence \( \omega \in \Sigma(\mu_a) \subset \Sigma(I) \). Condition (iii) implies that \( \xi \notin \ell^1 \).

The pair \( \xi, I \) has the following property which as we will show does imply that \( \dim \begin{pmatrix} I \colon B(H) \end{pmatrix} = \infty \): there is a strictly increasing sequence of indices \( p_i \) such that for every \( \chi \in \Sigma(I), (\chi_{\xi_a})_{p_i} \to 0 \) for some integer \( m \in \mathbb{N} \).

Indeed, for every \( \chi \in \Sigma(I) \) there are \( \alpha \in \mathbb{C}_\ast \), \( M > 0 \) and \( m \in \mathbb{N} \) for which \( \chi \leq \alpha \mu + MD_m \xi \) and so

\[
\begin{align*}
(\chi_{\xi_a})_{p_i} & \leq \frac{(\alpha \mu)_{p_i} + M(D_m \xi)_{p_i}}{(\xi_a)_{p_i}} \\
& \leq \frac{\alpha p_i \mu_{p_i} + M \xi_{p_i}}{(\xi_a)_{p_i}} \quad \text{by the monotonicity of } \alpha \text{ and } \mu \\
& \leq m \frac{\alpha p_i \mu_{p_i} + M \xi_{p_i}}{(\mu_a)_{p_i}} \quad \text{since } (\xi_a)_{p_i} \geq \frac{1}{m} (\xi_a)_{p_i} \\
& \leq 2m \frac{\alpha p_i \mu_{p_i} + M}{m} \rightarrow 0 \quad \text{by (ii) and (iii)} \\
& \leq 2m(\alpha p_i + \frac{M}{m}) \rightarrow 0 \quad \text{since } \mu_a \geq \mu.
\end{align*}
\]

We proceed now to prove that the codimension of \([I, B(H)]\) is infinite. For each positive integer \( N > 1 \) and \( 1 \leq j \leq N \), choose strictly increasing sequences of indices \( m_{k}^{(j)} < n_{k}^{(j)} \) where for all \( k \in \mathbb{N} \):

(a) \( n_{k}^{(j)} \in \{p_i\} \) and when \( n_{k}^{(j)} = p_l \) then \( l \geq k \).

(b) \( \sum_{i=m_{k}^{(j)}}^{n_{k}^{(j)}} \xi_i \geq 3 \sum_{i=1}^{m_{k}^{(j)}} \xi_i \).

(c) \( m_{k}^{(j-1)} = kn_{k}^{(j)} + 1 \) for \( 2 \leq j \leq N \).

(d) \( m_{k+1}^{(N)} = \min \{i \mid \xi_{kn_{k}^{(1)}} \geq N \xi_i\} \).

To construct the sequences \( m_{k}^{(j)} \) and \( n_{k}^{(j)} \), start with \( m_{1}^{(N)} = 1 \) and choose \( n_{1}^{(N)} \in \{p_l\} \) satisfying (b), which is possible since \( \xi \notin \ell^1 \). Then set \( m_{1}^{(N-1)} = n_{1}^{(N-1)} + 1 \) according to (c). Alternating between (b) and (c), obtain \( m_{1}^{(j)}, n_{1}^{(j)} \) for \( 1 \leq j \leq N \). Then choose \( m_{2}^{(N)} > n_{1}^{(1)} \) so to satisfy (d), which is possible since \( \xi \in \mathbb{C}_\ast \). Continue then the construction for \( k = 2 \) and so on. So for each \( k \),

\[
m_{k}^{(N)} < kn_{k}^{(N)} < m_{k}^{(N-1)} < kn_{k}^{(N-1)} < \cdots < m_{k}^{(1)} < kn_{k}^{(1)} < m_{k+1}^{(N)}.
\]
Then define $N$ sequences $\eta^{(j)} \in \mathbb{C}^*$ by setting

$$ (\eta^{(j)})_i := \begin{cases} 
\min (j, p) \xi_i, & \text{if } m_k^{(p)} \leq i \leq k n_k^{(p)} \text{ for } 1 \leq p \leq N \\
\min (\xi_{kn_k^{(1)}}, j \xi_i), & \text{if } kn_k^{(1)} < i < m_k^{(N)}. 
\end{cases} $$

Thus $\xi = \eta^{(1)} \leq \eta^{(2)} \leq \cdots \leq \eta^{(N)}$ and $\eta^{(j)} \leq j \xi$ so that $\eta^{(j)} \in \Sigma(I)$ for every $1 \leq j \leq N$.

To illustrate this construction, the following figure provides a continuous analog of the sequences $\eta^{(1)}, \eta^{(2)}$ and $\eta^{(3)}$ for the case $N = 3$.

![Diagram](image)

To prove that the cosets $\text{diag} (\eta^{(j)}) + [I, B(H)]$ are linearly independent, suppose $\text{diag} \sum_{j=1}^N \lambda_j \eta^{(j)} \in [I, B(H)]$ for some $\lambda_j \in \mathbb{C}^N$. Since $[I, B(H)]$ is self-adjoint and the sequences $\eta^{(j)}$ are real-valued, one can assume without loss of generality that $\lambda_j \in \mathbb{R}^N$. Define $\zeta := \sum_{j=1}^N \lambda_j \eta^{(j)}, \gamma_1 := 0, \gamma_p := \sum_{j=1}^{p-1} \lambda_j$ for $2 \leq p \leq N$ and $\beta_p := \sum_{j=p}^N \lambda_j$ for $1 \leq p \leq N$. A direct computation shows that $\zeta_1 = (\gamma_N + N \beta_N) \xi_1$ and that

$$ \zeta_i = \begin{cases} 
(\gamma_p + p \beta_p) \xi_i, & \text{if } m_k^{(p)} \leq i \leq k n_k^{(p)} \text{ for } 1 \leq p \leq N \\
\gamma_p \xi_i + \beta_p \xi_{kn_k^{(1)}}, & \text{if } kn_k^{(1)} < i < m_k^{(N)} \text{ and } (p - 1) \xi_i \leq \xi_{kn_k^{(1)}} \leq p \xi_i \text{ for } 2 \leq p \leq N.
\end{cases} $$

Setting $\gamma = \max \{\gamma_p + p \beta_p\}$, we claim that $|\zeta_i| \leq \gamma \xi_i$ for every $i$. If $m_k^{(p)} \leq i \leq k n_k^{(p)}$ for some $k \geq 1$ and some $1 \leq p \leq N$, then $|\zeta_i| = |\gamma_p + p \beta_p| \xi_i \leq \gamma \xi_i$. And if $kn_k^{(1)} < i < m_k^{(N)}$ and $(p - 1) \xi_i < \xi_{kn_k^{(1)}} < p \xi_i$ for some $k \geq 1$ and some $2 \leq p \leq N$, then $\zeta_i = \gamma_p \xi_i + \beta_p \xi_{kn_k^{(1)}}$. Assuming that $\zeta_i \geq 0$, one has

$$ 0 \leq \zeta_i \leq \begin{cases} 
(\gamma_p + p \beta_p) \xi_i, & \text{if } \beta_p \geq 0 \\
(\gamma_p + (p - 1) \beta_p) \xi_i = (\gamma_{p-1} + (p - 1) \beta_{p-1}) \xi_i, & \text{if } \beta_p < 0.
\end{cases} $$
In either case, $\zeta_i \leq \gamma \xi_i$. In the case that $\zeta_i < 0$, the same argument can be applied to $-\zeta_i$ to obtain the claim.

The crux of the proof is to show that $\gamma = 0$, whence an elementary computation will show that the linear system of the $N$ equations $\gamma_p + p\beta_p = 0$ has only the trivial solution $\lambda_1 = \lambda_2 = \cdots = \lambda_N = 0$, i.e., the $N$ cosets are linear independent. To prove that $\gamma = 0$, first choose $1 \leq r \leq N$ for which $\gamma = |\gamma_r + r\beta_r|$. Then for every $m_k^{(r)} \leq n \leq kn_k^{(r)}$ and every $n' \geq n$, one has $|\zeta_{n'}| \leq \gamma \xi_{n'} \leq \gamma \xi_n = |\zeta_n|$. This implies that if $\pi : \mathbb{N} \to \mathbb{N}$ is an injection for which $|\zeta_{\pi}|$ is monotone nonincreasing, then \( \{\zeta_i \mid i = m_k^{(r)}, \ldots, n\} \subseteq \{\zeta_{\pi(i)} \mid i = 1, 2, \ldots, n\} \). Define the set

\[ \Lambda_n := \{\pi(i) \mid i = 1, 2, \cdots, n\} \setminus \{m_k^{(r)}, \cdots, n\} \]

Then $\text{card} \: \Lambda_n = m_k^{(r)} - 1$ and, from the monotonicity of $\xi$ and the fact that $|\zeta_i| \leq \gamma \xi_i$, for every $i$,

\[
|\sum_{i=1}^{n} \zeta_{\pi(i)}| = |\sum_{i=m_k^{(r)}}^{n} \zeta_i + \sum_{i \in \Lambda_n} \zeta_i| \geq |\sum_{i=m_k^{(r)}}^{n} \zeta_i| - \sum_{i \in \Lambda_n} |\zeta_i| \\
= \gamma \sum_{i=m_k^{(r)}}^{n} \xi_i - \sum_{i \in \Lambda_n} |\zeta_i| \geq \gamma (\sum_{i=m_k^{(r)}}^{n} \xi_i - \sum_{i \in \Lambda_n} \xi_i) \\
\geq \gamma (\sum_{i=m_k^{(r)}}^{n} \xi_i - \sum_{i=1}^{m_k^{(r)}-1} \xi_i).
\]

If additionally $n_k^{(r)} \leq n \leq kn_k^{(r)}$, then combining this with the inequality in (b) yields that $|\sum_{i=1}^{n} \zeta_{\pi(i)}| \geq \frac{\gamma}{2} \sum_{i=1}^{n} \xi_i$, that is, $|((\zeta_{\pi})_a)_n| \geq \frac{\gamma}{2} (\xi_a)_n$. The assumption that $\text{diag} \: \zeta \in [I, B(H)]$ implies, by Theorem 2.2, that $|((\zeta_{\pi})_a)| \leq \rho$ for some $\rho \in \Sigma(I)$. But then, by the first part of this proof, there exists an $m \in \mathbb{N}$ for which $(\frac{\gamma}{\xi_a})_{m\rho} \to 0$. As $(\frac{\gamma}{\xi_a})_{m\rho} \geq \frac{\gamma}{2}$ for all $k \geq m$ and as $n_k^{(r)} \in \{p_i\}$, it follows that $\gamma = 0$, which concludes the proof.

In contrast to the other results on codimension in this paper, the proof of Theorem 7.8 does not seem to yield uncountable codimension.

**Corollary 7.9.** The second part of the proof of Theorem 7.8 shows that its conclusion holds for a larger class: if $I$ is an ideal for which there exists a nonsummable sequence $\xi \in \Sigma(I)$ and a monotone sequence of indices $\{p_i\}$ so that for every $\chi \in \Sigma(I)$ there is an associated $m \in \mathbb{N}$ for which $(\frac{\chi}{\xi_a})_{m\rho} \to 0$, then $\dim \left[ \frac{I}{[I, B(H)]} \right] = \infty$.

Acknowledgments. We wish to thank Daniel Beltita for his input on this paper, and Ken Davidson and Allan Donsig for their early input on the research.
